A sidereal clock is often considered a necessary adjunct to an equatorial mounting, in order to find objects invisible to the naked eye. But it may be dispensed with by the following method of "differentiation" in all cases, excepting during the brief season of twilight, when neither sun nor stars can be employed. Write down the difference of Right Ascension (taking particular notice whether additive or subtractive) between the required and some known object—the sun by day, a neighboring bright star by night. Seek the known object by the finder, and place it in the centre of your largest field; clamp the R. A. circle; set the telescope to the declination of the object sought, and clamp it there; unclamp in R. A. and move the telescope E. or W., as the case requires, to the value of the ascertained difference in R. A., and the object will be found in the field, somewhat W. of the centre, by a distance dependent on the duration of the process.

An observatory is by no means essential, but it would be difficult to overestimate its advantage in point of comfort as well as economy of time. It used to be an expensive luxury; but a very simple and cheap "telescope-house," combining shelter with open-air freedom, to the great merit of which I can bear full testimony, has been devised by the Rev. E. L. Berthon, and is described in the *English Mechanic*, Oct. 13 and 20, 1871. The Rev. W. Conybeare Bruce has also handled the subject very ably in the same publication, Feb. 6 and 27, and April 2, 1880.

We will close this section with the encouraging words of the Council of the Royal Astronomical Society, in their Report for 1828: "Every one who possesses an instrument, whose claims rise even not above a humble mediocrity, has it in his power to chalk out for himself a

* A very cheap equatorial stand is described in *Astron. Register*, xiv. 35. Franks observes that a common equatorial mounting may be made very efficient at a trifling expense by the addition of plain metal circles, on which slips of paper graduated with pen and ink are fastened by glue dissolved in strong acetic acid, and afterwards sized and varnished. A good pillar-stand may be made by letting a 4-inch iron pipe deep into the ground, in which a small table with a long foot revolves.

useful and honorable line of occupation for leisure hours, in which his labor shall be really valuable, if duly registered; . . . those who possess *good* instruments, have a field absolutely boundless for their exertions."—*From advance sheets of Webb's Celestial Objects for Common Telescopes.*

Etching on Copper.

SINCE the publication of the articles on Collodio-Etching, we have had several inquiries in regard to the method of etching on copper. The simplest and most thorough directions to amateurs for pursuing this interesting art are those by R. Scott Burn, which we here reproduce. The art of etching is not difficult to acquire, the principal requisite being the ability on the part of the operator to draw freely and accurately.

It will be our endeavor to describe the process in such a clear manner as to enable any one who has a knowledge of drawing to make a successful plate.

Etching enables us to produce lines on a metal plate capable of throwing off an impression. To effect this, it is necessary to cover the plate with a preparation which will resist acid. If on such a preparation acid is applied, it will not act on the copper; but if a scratch is made through the preparation, and the acid thereafter applied, it will eat into a line, deeper or shallower, according to the length of time the acid is allowed to remain. The metal generally used for etching is copper, the plates of which should be carefully prepared.

Etching is not meant, as some suppose, to be an easy method of imitating line-engraving; in fact, the grand distinction between the two styles is this, that in line-engraving the lines, however beautiful in effect, are produced by means more or less mechanical, while in etching, the lines and effect are put in with a facility of drawing and freedom of touch which is displayed in free pencil-sketching on paper. In etching, the needle and the aquafortis are the only assistants; the graver is seldom required, and the oftener it is used, the stiffer the drawing becomes, and more removed from that exquisite freedom and ease which is the characteristic of a true etching, representing, as it does, or ought to do, the ease with which the original design or subject is transferred to the paper or the canvass.

First, as to the "etching ground" This is a preparation of wax, asphaltum, etc., the following being a favorite recipe: Take of beeswax and asphalt two parts each; Burgundy pitch and black pitch 1 part each. Melt the wax and the pitch in an earthen vessel, and add the asphalt by degrees in fine powder. Expose to heat until a drop, which has been cooled, breaks by bending back and forth two or three times in the fingers. As much depends on the quality of the ground, the expense not being great, we would recommend our readers to purchase it ready made. It is sold by most of the dealers in engravers' tools, etc. In order to prevent any grit coming to the plate, it is better to inclose the ground in silk for the purpose of filtering any imperfection.

The following tools and implements are necessary: The "dabber," which is composed of silk of a fine texture, and evenly stuffed with wool until it assumes the form required (Fig. 1). It is necessary to place

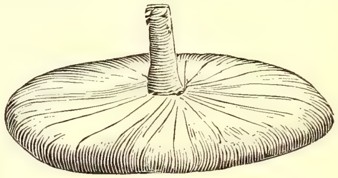

Fig. 1.

a circular piece of card at the top of the dabber, immediately below the handle. The "etching-point," the "graver," the "scraper," the "burnisher," and the "hand-vice." An etching table must also be provided, with the following accessories: A copper plate on which the subject is to be etched, with support and ruler. Looking-glass for the purpose of reversing drawing. Tissue paper strained on a thin frame to prevent the light from glistening too much on the plate. Black varnish for stopping out scratches and such tints as are "bit" sufficiently dark. Nitric acid. Water. Spirit of turpentine. An ordinary china or earthenware plate and pencils for mixing the varnish.

Fig 2. ETCHING POINT.

Fig. 3. GRAVER.

Fig, 4. SCRAPER.

Fig. 5. BURNISHER.

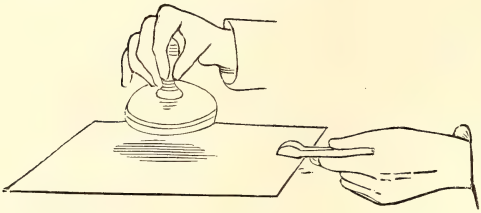

Fig. 6.

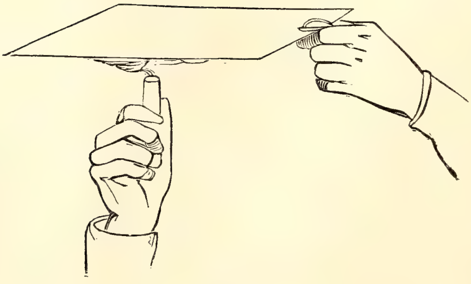

Fig. 7.

The first preparatory process is laying the etching-ground.

The plate having been polished from tarnish, in order to remove all grease from the surface, wash it well with spirit of turpentine, and, after the plate is dry, rub it carefully with whiting and wash-leather; then fix the hand-vice, and proceed to heat the plate either on the top of a stove, or by any other process by which a steady and not too great a heat may be obtained; in the absence of a stove, a piece of flat metal, heated and placed on bricks, is a good substitute. It may be known when the plate is sufficiently hot, by placing the etching-ground on the plate with a gentle pressure, and, after allowing it to remain a few seconds, pass it slowly from one end of the plate to the other; if a thin layer is equally left along the surface, the heat is proper. Continue to pass thin layers of etching-ground from end to end of the plate, at tolerably equal distances, and then, in the same manner, from side to side; the object of this is to place an equal quantity of etching-ground, in order that the dabber may spread it more readily over the surface; then take the dabber (Fig. 6), now in requisition, and use it by constantly dabbing over the plate for the purpose of entirely covering the portion of the plate required. When an even and complete layer has been obtained, take a wax-taper (Fig. 7), and next proceed immediately to smoke the ground; the taper must be kept in motion, in order that the whole of the ground may be evenly blacked; if the flame of the taper is allowed to remain too long in the same position, the ground will be burnt, and not offer sufficient resistance to the acid; and if the plate, during the process of smoking, is too cold, the smoke will not incorporate itself with the ground, but remain on the surface. The essentials of a good ground are, first, that the surface be *completely covered;* second, the covering to be as equal as possible, and not so thick as to prevent the free use of the etching point; and third, that it shall present, when cold, a polished black surface. If, when the plate is cold, the surface appears in parts dull, it is caused either by the ground being burnt by using too much heat while spreading the ground, or that, when smoking, the plate has been too cold. It is easy, when the plate is cold, to discover from which of these causes the dulness of the surface proceeds, by rubbing the part slightly with a soft handkerchief; if the black is removed to the handkerchief, the plate has been too cold when the taper was applied; but if the dull black remains on the plate, the imperfection has been caused by heat. If the dulness arises from the smoke lying on the surface, it may be readily altered by slightly heating the plate; if from burning, the ground must be removed by heat and spirit of turpentine, and the plate again thoroughly cleansed.

The best method of getting the subject transferred to the plate is to send a careful outline, either in pencil or red chalk, to a copperplate-printer, who will slightly damp and pass it through the press. If this is not convenient, a piece of tissue paper may be rubbed with powdered vermillion, and fixed with the colored side towards the plate. The tracing must then be put in its proper place, and fastened with wax at the corners to prevent it shifting. The outline must be then gone over with a blunt etching-point. This process will leave a clear outline in red, on a black ground. When thus transferring, the pressure should not be so strong as to damage the etching-ground.

The student will observe that, in order that the plate may throw off a correct impression, the subject must be reversed. This difficulty may be remedied by placing the drawing so that it may be seen in a looking-glass, which will have the effect of giving it the same appearance that it would have on the plate.

The plate is now prepared for the etching process.

A New Breed of Whales.—A whaling captain, lately returned from the Arctic seas, declares that a new breed of whales have made their appearance in those waters. They are supposed to have emigrated from the open sea at the Poles.

The Crawfish and the Minnow.

A FISH STORY IN RHYME.

BY L. M. HOSEA.

A pert little crawfish, crustaceous and fat,
Voting ancestral shingles and shallows a bore,
Determined one day, 'spite of warnings and all that
His elders could say, to remain there no more;
But to see the great world in the deeper blue water,
And the wonders of mid-channel far from the shore.

"You silly young brachi'pod"—spoke his old granny,
(Hard-shell old Baptist, with claws like a vice),
"Don't be a fool, like the genus humani,
"Those air-breathing bipeds who never grow wise,
"Except in exchange of expensive experience.
"Be happy at home, sir; there! that's my advice."

Then big Papa Crawfish: "Out there in the brine
"Are Ichthyosauri, and terrible Ptero-
"Dactylian reptiles, and catfish a-sighin'
"For juicy young headstrong crustaceans, who ne'er o-
"Vercame their propensity backward to wander,
"And hold their papa's admonitions at zero."

"Pooh!" quoth this impertinent juv'nal, "keep easy!
"Tell that to marines! D'ye see any green?"
And he put up one claw to his eye. "As for Ichthy-
"O'Soreeye, that's thin, much too thin to be seen.
"And as for that Terry Dac-what's-his name, why—
"Just let me alone; I'll run my machine."

Well, nothing would do this precocious knight-errant
But to wander abroad in the wide wat'ry world,
Over shingle and mud-bank, out into the current—
The pitiless current—that seized him and hurled
Him far out among swift darting fish, in the torrent
That rolled him and tossed him where angry waves curled.

Affrighted, dismayed, clutching wildly at naught,
Borne on by the flood in its fatal embrace,
He at length on a rock in mid-channel was caught,
And clung with despair to the shallowest place.
Cruel fish sported round in the swift-moving wat-
Er, where eddy chased eddy in mad whirling race.

Old Crusoe was never so much isolated,
On his little isle in the wide waste of sea,
As this little decapod—lonely, ill-fated,
Repentant young prisoner—bound by decree
Of the water-god fast to that rock, as I've stated,
With hungry fish waiting there under its lee.

He thought of his home—of the scenes of his childhood—
His playmates—his teeter-board, marbles, and ball—
His dinners of grub in the brook through the wildwood—
How hungry that made him!—and, lastly of all,
His own foolish boasts, which, to draw it but mild, would
Prove that pride ever precedes a great fall.

By-and-by came a minnow, borne on by the race,
And strayed in the eddy there formed in the tide,
Seeking refuge from divers (not sun-dry) great bass,
Whose fierce-gleaming armor-scales, mouths opened wide,
And pitiless optics, all threatened disas-
Ter to such little fish as in deep waters glide,

But, strange to relate, while such perils environ,
It pops in the head of our foolish young friend
To fall dead in love with that luscious young siren
(Siren? that's wrong; but no matter), and end
His misguided existence; and all for aspirin'
To things far beyond him, as I apprehend.

For, reaching out softly to clasp his fair prize in
His long taper claws, thinking only of love,
A bass darted up like a flash, or a rise in
Stocks, from dim depths to the surface above.
His jaws fiercely clapped on the minnow, entrapped
Thus by clap-trap—like many a poor human dove.

Now crawfish are curious creatures; behind them—
Like folks who leap blindly—ne'er viewing the goal,
They travel tail-foremost, and frequently find them-
Selves out of the plain road in some pesky hole;
Or, to finish this stanza as old Sancho Panza
Would—"Out of the frying pan into the coal."

So 'twas in this instance; the foolish macruran,
Scared out of his wits by the sudden attack,
To 'scape the fell jaws, darted back in a jiffy
Tail-foremost, of course, like a born maniac,
And fell plump in the jaws of another bass waiting,
Who gobbled young crusty in one single smack.

Moral:

So ends the sad tragedy; ring down the curtain.
The moral has troubled me more than you'd think.
For, if it be obvious, then it is certain-
Ly useless to waste on it paper and ink.
But if it be not so, why then it were better
Than writing this "pome," to have paused on the brink.

But the plain, simple truth is, in this case at least,
It's no dearth of morals that troubles me so.
I'm embarrassed with wealth—like the boy at the feast
When the pudding came on; and I really don't know
Which to choose; and therefore I mildly suggest
To you, Reader, to capture the one that suits you.

Cincinnati, March, 1881.

Three Amateur Workers—and What They Did—IX.

BY FRED. T. HODGSON.

"NOW," said Mr. Carpenter, on the following evening, "I will show you how to make the furniture for Jessie's play-house; but before we proceed to business it will be necessary that you be informed on a few matters touching the use of some

Fig. 30.

other tools I have procured for you, and a style of work you have not yet performed; namely, mortising and tenoning. A mortise is a hole of some given dimensions

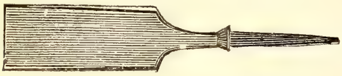

Fig. 31.

cut into a piece of wood or other material. Its object is to receive a tenon which is fitted tightly into it, and the two pieces thus framed together generally form a right angle. The mortise is made by first

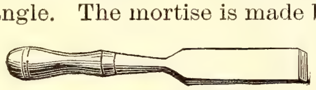

Fig. 32.

boring a hole at one end of it with a bit not larger than the width of the mortise. A chisel is used to remove the other portions of wood. The chisel is driven into the wood with a wooden mallet until it is more than half way through the stuff being mortised; the "core," or wood that

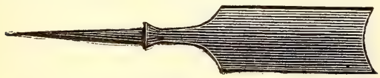

Fig. 33.

has been moved by the chisel, is then pried out of the mortise, and another cut is taken, and so on until the mortise is all cut on the one side. The piece is then turned over, and the same operations are gone through. You will notice that the mortise is "laid out" or marked on both sides of the stuff. On small stuff this is accomplished by using a mortise gauge, which you see is something like the single gauge you have been using, only it has a screwed spur, which can be adjusted to any width of mortise within the capacity of the tool, by a slide that is movable in a

Fig. 34.

slot. Sometimes this slide is controlled by a thumb-screw, which is attached to the end of the stem.

When the "core" or chips are all cleaned out of the mortise with a firmer chisel, and the ends properly squared down, it is then ready to receive the tenon.

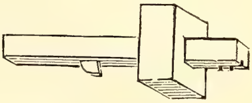

Fig. 35.

A tenon is formed with a saw, or rather with two saws—a rip saw being used to cut down the tenon lengthwise of the grain, and a back saw for cutting the shoulders. The gauge used for markin the mortises must be used for laying out the tenons without being changed."

Mr. Carpenter then explained how the lines were carried over the stuff to show the shoulders on the tenons and the ends of the mortises, with the try-square. It is often a puzzle to young people to discover how a line can be carried round the four sides of a piece of stuff and join without any divergence. If a piece of stuff is straight and parallel on every side, and a *true* try-square be applied with its stock against one edge, and the blade lapping over a side at right angles with the aforesaid edge, then a fine line drawn on the stuff along the edge of the blade; then

---

Fig. 30 shows a socket mortising chisel. Fig. 31 is an English duck-bill mortise chisel; the handle is made of wood and fits on the shank. This kind of chisel is seldom used now. Fig. 32 is a framing chisel, and Fig. 33 is a gouge. Fig. 34 shows a mallet. This is used to strike the handle of the chisel with when making a mortise; sometimes mallets are made with a square head and oval handle. Fig. 35 shows a mortise gauge of the cheaper sort. This can be made to do exact work if everything is tight about it.

the stuff turned, and the same operation repeated, with the blade of the try-square made to coincide with the work already made, there will be no difficulty in understanding the reason why any line may be

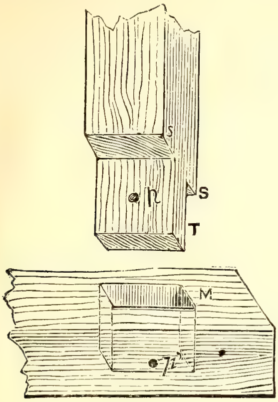

Fig. 36.

carried round a piece of *trued* stuff so that all the lines will meet at the corners, and yet be at right angles with the edges of the stuff.

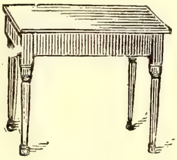

Fig. 37.

This matter being now fully understood, Mr. Carpenter instructed the boys how to make a table like the one shown in Fig. 37. The legs and sides were cut out with

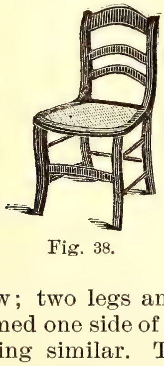

Fig. 38.

the scroll saw; two legs and one side in one piece formed one side of the table, the other side being similar. The ends were cut out seperately, and were glued and bradded on to the legs, as shown. The following are the dimensions of the pieces used in making the table:

Height of legs and sides, 2¾ inches.

Length of sides over all, including legs, 5½ inches.

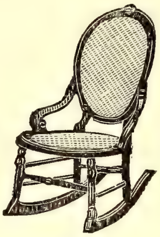

Fig. 39.

Length of the end pieces over legs, 2½ inches.

Length of table top, 6 inches.

Width of table top, 3 inches.

Width of end and side pieces, half-inch.

The stuff used for the table should not

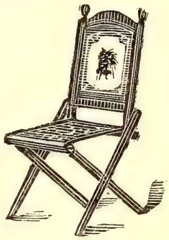

Fig. 40.

be less than half an inch thick, and may be of white-wood, pine, or other soft wood, and, when finished, should be painted in appropriate colors.

Fig. 36 shows a tenon and mortise. The tenon, T, should seldom exceed one-third of the thickness of the stuff, otherwise the piece containing mortise, M, will be weaker at that part than the tenon. After the tenon has been driven home, so that the shoulders, S S, bed fairly on the surface of the wood around the mortise—in which they will fail if all the parts be not exactly square—the hole, *p p*, must be bored, but rather smaller than it will ultimately be required. The tenon must then be withdrawn from the mortise, and the hole, *p*, be enlarged to the proper size for the pin; *p* must also be increased to the same size, but its centre is removed a trifle towards the shoulders, S S, so that when the tenon is reinserted in the mortise, the holes, *p p*, will not exactly tally. The discrepancy should be very slight, otherwise the tenon may be split when the pin is driven home. By setting the hole in the tenon a little behind that in the mortise, the pin is enabled to draw the tenon forward until both the holes correspond, when the shoulders, S S, will bear firmly on the surface, M.

It will be noticed that the table is made on the same scale as that used in building the house, and the other pieces of furniture that follow will be built on that scale also.

A good height for a dining table is about 2 feet, 8½ inches. The one described will, when finished, represent a height of 2 feet nine inches, or, by actual measurement, two inches and nine-twelfths, which, according to our scale of one inch to the foot would represent a table two feet nine inches high, by six feet long and three feet wide.

In making the chairs, each side of Fig. 38 should be cut out of one piece, and the cross pieces on the front, back and seat should be tenoned, and fit into mortises in the side pieces and legs. Small chairs like this may be sawed out of the solid, but this requires a larger saw than the one Fred and Ellwood now possess.

The rocking-chair, Fig. 39, should have the back and two legs cut out of one piece, the seat out of another, and one front leg, rail, and one rocker out of another. The scrolls forming the arms and the one front rail, are cut from separate pieces. The back legs are tenoned into the rockers, and the front legs are tenoned into the seat; the front rail is also tenoned into the front legs. The scrolls or arms are glued on and bradded; the back legs are also bradded and glued to the seat.

The camp chair, Fig. 40, requires no explanation; the construction is so simple that the boys found no difficulty whatever in making one. A few straight strips of walnut half an inch wide, and less than a quarter of an inch thick, were used for the frame, and a narrow strip of flowered silk was used for the seat and back; this was glued to the strips where necessary.

Eighteen inches is the height to make a chair seat, from the floor, and the height of a back should be about two feet ten inches. This would make our chairs one and a half inches high to the top of seats, and two inches and five-eighths to the top of backs. These sizes make the chairs in the same proportion as the house.

An Old Cement Revived.

MANY years ago it used to be a practice amongst housewives to mend broken china and crockery ware very thoroughly and in a very simple manner. The plan has fallen into disuse, and although it is *mentioned* in one or two books, we know of no case in which it is *described*, and it is years since we met any person who is familiar with it.

The plan is simply to bind the broken surfaces firmly together, and boil the article in skim-milk. We have seen cups, plates, bowls, and other articles which seemed to be beyond all possibility of being repaired, mended in this way, so as to be almost as good as new, the joints being very strong and almost invisible.

The secret of success seems to lie in binding the parts firmly together, and boiling for a sufficient length of time. The tying together of the pieces of a round cup or bowl is not a very simple matter, but it can be done by going the right way to work. First, arrange the parts in their proper positions, and, if a bowl, set it mouth down, as the pieces will keep their arrangement best in this position. Then wind stout tape round the article, so as to hold the pieces together. Tape is far better than twine, and some pieces should be kept for this purpose. It is easy to draw the tape tight until we come to tie the ends, and then special devices must be used. When sufficient tape has been wound round the article, let one person hold it from slipping, by pressing a finger firmly on each end, and then let another person tie the ends in a firm knot, but leaving the tape so loose from the article that a pencil or stout skewer may be passed under it. Then by twisting the skewer the tape is tightened in the same way that a surgeon compresses an artery with his tourniquet, and by passing the fingers over the tape, and smoothing it forward toward the ends, all the pieces may be pressed together with a firmness that cannot be obtained in any other way.

The article should now be placed in a pan of cold milk (skim-milk is the best and cheapest), which should be gradually

heated to the boiling point, and kept at this temperature for some time—say half an hour to an hour—care being taken not to allow it to burn. The articles are allowed to cool in the milk, and when taken out are wiped dry and allowed to stand for a day or two until the cement has become quite hard. They may then be washed off with warm water, and the parts will be found to be strongly cemented together. The same milk may be used again, but not with such good effect. Generally, however, it is possible to pack quite a number of articles in the pan in the first place, especially if they can be *nested*, or placed one within the other.

Lens Making.

A WRITER in the *English Mechanic* thus describes his method of grinding and polishing lenses:

So far as microscopic glasses are concerned, the modes usually proposed are very tedious, troublesome, and most uncertain. I have devoted many years to making for my own use achromatic and other lenses for microscopic object-glasses; and as it may be useful to some who grind their own, I send a general description of the way I go to work, first stating that I take from ten to twenty minutes to make a plano-convex from the rough, if no accident happens.

I take a piece of glass and cement it to a chuck, and then turn it with a hard steel tool to the required radius. There is no trouble in doing this if the tool is wetted with saliva. I find this far superior to anything else. I then grind it smooth with a brass tool, and, after washing, go on grinding it with the same emery, only covering the tool with a bit of silk. I use oil just at first, and then water. This will go some way towards polishing. I then clear away the emery, and work the glass on the silk with putty powder, now making the lens revolve for a little time till all scratches are nearly removed, and then finish it with the tool revolving. The reason for making the lens revolve is that the putty powder acts very much quicker, and so saves time and trouble. The emery I use is the common flour-emery washed once. I use the finest part, and this is quite enough, as I turn the lens to the right shape, so that it requires very little coarse grinding. While the lathe gives a circular motion, the hand should move backward and forward, changing the position of the lens. This gives a true figure. I use different silks for slight alterations in the focus.

Something Nice.

WE have just secured a few miniature "charm" opera-glasses, which we feel sure will please those of our readers that get one. These little opera-glasses are of white ivory, being single tubes about half an inch long, and having an opening through them of about a sixteenth of an inch in diameter. On looking through this hole in the same way that we would look through a common spy-glass, there will be seen a portrait, view, or enlarged picture, of the Creed, Lord's Prayer, etc. These pictures are so small as to be quite invisible to the naked eye, but there is a powerful magnifier in the little ivory tube, and when we look at the pictures through it they appear to be quite large and very distinct.

We will send one of these postpaid to any of our subscribers that will procure for us another subscription, and send on the fifty cents. For all sums under one dollar we accept postage stamps at their full value.

Correspondence.

A Wise Woodpecker.

Ed. Young Scientist—Last summer, while walking in the woods, I found the nest of a golden-winged woodpecker (*Colaptes Auratus*) built in the hollow of a dead tree. Wishing the eggs for my collection, I got a boy to climb the tree and collect the eggs for me, which he did with little trouble. A few days later, while walking by the same tree, I heard the woodpecker hard at work deepening the hole which had previously contained the eggs, with a view, I suppose, of protecting its eggs in future from all mankind, which I have no doubt it succeeded perfectly in doing.

ALEXANDER G. GIBBS.

EXCHANGES.

Only those who are *yearly* subscribers, and whose names are entered on our books have the privilege of inserting exchanges.

Exchanges must be on separate slips of paper or postal cards. If mixed with business letters or cards they cannot be used.

Exchanges must not exceed thirty words.

Buying and selling belong to the advertising department.

We reserve the right to omit the exchange column, when we have not room for it, and the amount of space at our disposal will regulate the number of insertions given to each *exchange,* the preference being always given to those who have not previously used our columns.

To exchange, for engine or offers, a pair of Bliss Telephones and 200 feet of copper wire. J. W. Grant, 402 Broad St., Newark, N. J.

To exchange, a 2½ octave chromatic xylophone for microscope, microscopical apparatus, scientific books, or offers. J. E. Moore, Box 81, Newcastle, Ind.

Photographic camera, with lens for taking 3¼ by 4¼ pictures, tripod, plate holder, printing frame, instruction book, etc., in exchange for electrical instruments or offers. W. Chamberlain, 446 Broome St., N. Y.

I have McAllister's Naturalists' Microscope, with achromatic triplet objectives, used only 2 months, cost $12.00. I wish to exchange for an inch or 2-3 inch objective. Address, with particulars, F. F. Colwell, Urbana, Champaign Co., O.

To exchange for offers; a small lot of microscopic mounting apparatus. List on application to J. N. B., Box 1468, N. Y.

To exchange, books and YOUNG SCIENTIST, and trinkets, for other books, revolver, or stylographic pen. Frank Bicknell, Humboldt, Iowa.

Ancient petrified grain, Indian pottery, birds eggs, papers, magazines, Confederate money, fossils, minerals, to exchange for arrow-heads, Indian relics, Confederate, Continental, and other paper money. Fred T. Brinkerhoff, Box 347, Neenah, Wis.

Minerals, tricks, copper coins, book on pigeons and rabbits, Wilson School History, for book on experiments, or specimens, minerals, stamps or coins. P. R. Bradley, Box 305, Dunkirk, N. Y.

Wanted, a second-hand screw cutting foot lathe, must be in good condition; state what is wanted in exchange, also size and make of lathe. G. A. Clark, Castalia, Iowa.

To exchange, minerals, shells, fossil shells, birds eggs, etc., for minerals, shells, fossils, stuffed birds, birds eggs, and books. U. S. Grant, Des Moines, Iowa.

Wanted, botanical correspondents for the coming season, also amateur correspondents in chemistry. L, Box 70, East Templeton, Wov. Co., Mass.

Wanted, to exchange a well-equipped job printing outfit, for books or offers. Frank A. Niblack, Rockport, Ind.

Will exchange for Vol. 2 of the YOUNG SCIENTIST, instructive books bound in cloth to the value of $1.50. Chas. H. Williamson, 293 Eckford St., Greenpoint, Brooklyn, N. Y.

I have a new Munsen's battery, large size, which I wish to exchange for a good revolver or offers. Robt. T. Boyle, 351 West 83d St., New York.

Hair of American deer to exchange for diatoms, foraminifera, or other material. W. H. Osborn, Chardon, Ohio.

To exchange, full instruction in short-hand writing, and birds eggs, for birds eggs, postage stamps, or offers. M. F. E., 51 Spencer St., Albany, N. Y.

"History of Our Country," by Lossing, in six parts, price $15, to exchange for printing press or offers. Frank Chandler, Waverley, Mass.

Fine Devonian and Carb. fossils for others, especially cretaceous fossils, scientific books or papers; Pitman's short-hand works for books or offers. A. Stapleton, East Point, Tioga Co., Penn.

Wanted, scientific books and apparatus; send lists and say what is wanted in exchange. Ewing McLean, Greencastle, Ind.

Wanted, specimens in geology, entomology, oology, etc., for those in other localities, also coins and a charm microscope (magnifies 1,000 times) for one having a different view. J. H. Jones, Frankfort, N. Y.

Send for exchange list of insects, especially Coleoptera and Lepidoptera. Philip Laurent, 621 Marshall St., Philadelphia, Pa.

For printing press or offers, achromatic telescope, $8.50; microscope, $5; set drawing instruments, $3; revolver, $3; Phrenological Journal, $2.50; books, 12 plays, farces, dramas, burlesques, etc., $1.80. F. E. Payne, Alma, Mich.

One pair 3 lb Indian clubs, one scroll saw, one pocket lantern, and a large number of books, for magic lantern, pair telephones, photographic camera, or offers. Thos. A. Black, Lock Box 678, Scranton, Pa.

For exchange, pocket lantern and instruction books for cornet and clarionet; wanted History of the "Franco-Prussian War," and the "Lost Cause." C. W. Hughes, Shreve, Wayne Co., Ohio.

I have Brown's heavy scroll saw attachment, worth $6, which I wish to exchange for a lathe chuck or offers. C. B. Russell, Waterbury Centre, Vt.

Will exchange magnets, electric battery, as good as new, cost £3 in England, for plating battery and materials, or offers. F. Whitehead, Box 55, St. Augustine, Fla.

American and foreign coins to exchange; state what you have. W. J. Allen, 126 Twenty-third Street, Brooklyn, N. Y.

To exchange, fine imported game fowls of the best strain for Fleetwood scroll saw, compound microscope, telescope, magic lantern, shot gun, or offers. E. Alexander, Johnstown, Fulton Co., N. Y. Box 47.

J. T. Bell, Franklin, Pa., has set of ivory chessmen, German flute, six extra keys, value $12, books, etc., to exchange for magic lantern, music box, guns, revolvers, or offers.

Birds eggs and arrow-heads to exchange for fossils and minerals, and birds eggs; send for my list. Clement G. Burns, Salem, Col. Co., Ohio.

Minerals (zeolites, etc.), to exchange for other minerals; state what specimens you have to exchange. H. L. Clapp, 35 West Cottage St., Roxbury, Mass.

Type, in exchange for curiosities, fossils, etc. Geo. K. Fischer, 729 North 6th St., Philadelphia, Pa.

I have some stamps which I would like to trade for stuffed birds, birds eggs and nests; I am also open to an offer; send for list of stamps. A. G. G., Box 26, Summit, New Jersey.

U. S. and foreign postage and revenue stamps for others; U. S. match and medicine especially; send list or sheet and I will do the same. B. M. Hammond, cor. Elm and Live Oak Sts., Dallas, Texas.

To exchange for 1 new Vol. II, Young Scientist, 1 new Vol. I of ditto, and Prof. Bell's Lectures on the Telephone. F. H. Burger, Chester, Pa.

I have 2,000 foreign stamps that I would like to exchange for others. F. Cushing, P. O. Box 178, Wattsburg, Erie Co., Pa.

Wanted, a hand or self-inking printing press, small size, in exchange for books, magazines, papers, etc. B. D. Howell, High Bridge, Hunterdon, Co., N. J.

Three Amateur Workers—and What They Did—X.

BY FRED. T. HODGSON.

THE following evening Jessie was anxious to begin work as soon as she returned from school. After the carpet was nicely bound with drab dress braid, Jessie proposed making some little rugs and mats of the smaller pieces. Mrs. Carpenter thought that it was a good idea, and proceeded to draw a large oak leaf on a piece of drawing paper that Fred had left on the table. "Why, Mamma, what are you going to do?" said Jessie, whose curiosity was aroused by so unusual a proceeding. "Well, Jessie, if you just watch me you will see."

After Mrs. Carpenter had traced the outline of the leaf on the paper, she cut it out and laid it on a piece of wine-colored plush.

"Oh, Mamma, I see what you are going to do now!" said Jessie, looking delighted as her mamma cut out the leaf and laid it on a stiff piece of canvas. "Now, Jessie, do you think you can button-hole stitch this evenly around the edges?" "Yes," answered Jessie; you know you showed me how to do the bottom of dolly's dress, and I have not forgotten how." "Well, then, Jessie, get some drab floss, or perhaps fine worsted would be the best for this one, and if you succeed in doing this nicely you may use floss for the next."

Jessie got the worsted, and her mamma did the first few stitches for her. Jessie's little fingers worked busily for about an hour, and half of the leaf was finished.

Some of the stitches were a little uneven, but, considering that Jessie was only nine years old, it was done very well.

"Mamma," said Jessie, "don't you think it would look nice with something in the centre, a little flower or vine?" "Yes, Jessie, it would be very nice, but I intended tracing the little veins, that are usually in oak leaves, and working them

with worsted. This is only an experiment, and, if we like the design, we may make some other, perhaps more elaborate, for the other rooms."

By this time Jessie had the little leaf stitched all round, and Mrs. Carpenter finished it. It was quite a pretty and odd device.

"Now, Jessie, here is a piece of plush, it is just the right size for a rug to put in front of the sofa, if we have one, or perhaps beside the bed; it is just twice as long as it is wide, and I think we will leave it as it is, and you can stitch it around as you did the other; and when that is finished, we will lay the carpet and rugs away until we are as far advanced with the other rooms as we are with this one, and probably by that time Fred and Ellwood will have the furniture ready to upholster." "Yes, mamma, I think that will be the best plan."

Mrs. Carpenter and Jessie were hard at work, when Ellwood came running in at half past nine to tell his mamma and Jessie that they were going to work a little later than usual, because Fred was anxious to finish one of the little cornices that night, so he could bring it in to show Jessie. Jessie was now getting sleepy, but insisted upon staying up until Fred came in. He soon made his appearance with his papa, and under his arm the cornice.

"What do you think of it, Jessie?" said Fred. "Think of it? why, I think it is just lovely!" answered Jessie, looking at it with delight, "don't you, Mamma?" Mrs. Carpenter thought it was very nice, of course.

"I fear you will make our boy vain, you praise him so much," said the father of this little flock, as Fred and Jessie were preparing to bring their evening's work to an end by putting their things away.

"Oh! no," said Fred, laughing, "little things like that don't affect me in the least;" but, nevertheless, Fred was pleased and proud of his work.

Jessie wanted to make the carpet for the parlor the next time her mamma and she sat down to sew for dolly's house, and Mrs. Carpenter consented. They had had a good many talks about furnishing this important room, and had decided to furnish it in blue, because, as Jessie said, "it would be so becoming to dolly's pinky complexion and golden hair." This carpet was to be made of canvas, the same as is ordinarily used for woolwork, perhaps a little coarser. Mrs. Carpenter had the canvas in the house, and cut it out, so that Jessie could begin to work it.

"The parlor floor measures 18 x 14 inches, doesn't it Jessie?" said Mrs. Carpenter, "so I have cut it one inch longer each way, and now you can hem it around the edges to prevent it from raveling."

As dolly's parlor was not to be used by any but herself, they selected the pretty shade of *ciel-blue* for the ground of the carpet, and the pattern was to be worked in some contrasting color.

The carpet was now commenced, and Jessie worked very dilligently at it in her leisure time. Mrs. Carpenter traced a little vine of moss rosebuds and leaves near the edge of the canvas, for a border, and they decided not to have anything in the centre, as the room was so small. Mrs. Carpenter worked the buds for Jessie with pale-shades of pink worsted, and Jessie did the leaves with drab, and then filled them in with blue.

Some time elapsed before Jessie commenced her carpet, but, being fond of work of that kind, it did not take her long to do it, considering that she went to school, and had some lessons to learn when she came home in the afternoon. The carpet was finished, however, and Jessie thinks there is nothing like it in this or any other country.

The boys having completed the house, and being anxious to make something for their mother, of whom they were very fond, decided to ask her if they could not make her something now; so the following morning, at breakfast table, they asked her if there was not something she wanted they could make for her.

"Well, children," said Mrs. Carpenter, "I would like either a nice toilet stand for Fred's room, or a small umbrella stand for the hall leading from the side entrance of the house, if you think you

are able to make either one or both of these articles."

This pleased the boys, and they immediately persuaded their father to assist

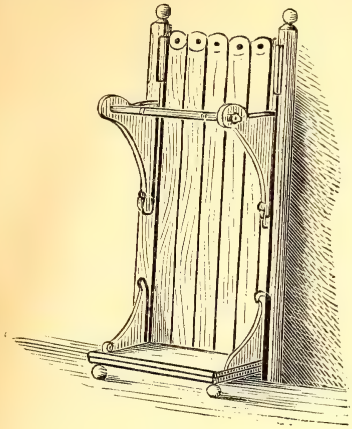

Fig. 41.

them to make the articles, and to purchase materials for them.

The engraving, Fig. 41, shows a design of an umbrella stand the boys decided to make. In our next paper we will see how they prepared their stuff and put the work together.

Etching on Copper.—II.

When etching, care must be taken to prevent any grease from coming into contact with the etching-ground; and it is proper to fix pieces of thin wood or folded paper round the edge of the plate, in order, with the help of a ruler, to form a sort of bridge on which to rest the hand. This precaution is necessary in order to protect the ground from scratches. These supports may be fastened with bordering wax. The etching-point is used in a similar manner to a blacklead-pencil; and it is very important to bring it into good working condition by rubbing it on a hone or leather strop. The point ought to be of such a degree of sharpness as to move freely on the plate; at the same time it is necessary that each line should go completely through the ground, otherwise the etching, after biting, will present a very rotten appearance.

Wax is now used for the purpose of forming a wall round the plate of about an inch high to confine the acid; it is composed of beeswax and Burgundy pitch, in the proportion of one pound of beeswax and a quarter of a pound of Burgundy pitch. The ingredients must be chopped into small pieces, and allowed to boil slowly in an earthen pipkin. As soon as the whole is dissolved, it is necessary to pour it into a basin partly full of warm water; it must then be worked by the hands until it becomes a pliable substance similar to shoemaker's wax. When using the bordering wax, it may be placed in hot water for the purpose of rendering it more workable, and it is necessary to be very careful to press it closely to the plate in order to prevent the acid from escaping (Fig. 8). It is also better to varnish round

Fig. 8.

the inside of the wax with great care, lest the ground underneath the wax may have been removed. If not thus protected, the margin will be filled with holes, which are troublesome to remove.

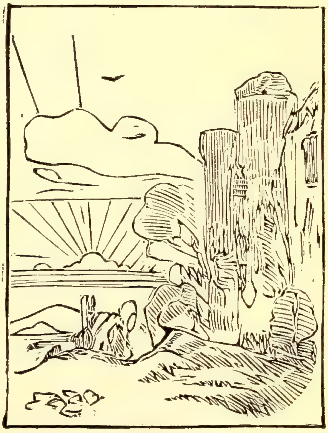

Fig. 9.

It is difficult to give any precise directions for biting, as much depends on the

strength of the acid, the hardness of the copper, and the degree of pressure which has been laid on the point when etching.

The following figures illustrate the appearance of the plate at different stages of the biting-in process. Fig. 9 represents the etching as it would appear after the acid had been applied five minutes; Fig. 10, the etching with the lightest tints

Fig. 10.

stopped up with varnish. Fig. 11 represents the etching as it would appear after

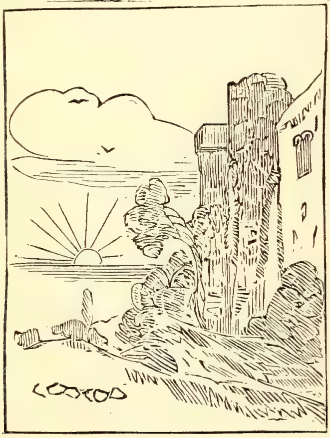

Fig. 11.

the acid has been applied ten minutes; and Fig. 12 after it has been applied fifteen minutes.

Generally the nitrous acid sold bydruggists may be diluted with a little more than twice the quantity of water; but until the student has by experience acquired a knowledge of the action of the acid, it will be advisable to make frequent

Fig. 12.

examinations of the etching, lest the tints are bit too dark. In order to effect this, the acid must be poured off, and then the plate carefully washed with water, and dried either by blowing with a pair of bellows or by dabbing with a very soft handkerchief; a portion of the etching-ground can then be removed by the scraper (see page 72). If the line is not dark enough the plate can be stopped up with varnish, and when dry the acid can be again applied. It is, perhaps, well to mention that the common *Brunswick black*, used for blacking chimney ornaments, is a very good varnish for stopping-out. This varnish may be had at any oil shop. A plate, if covered with this varnish, and permitted to dry, will as effectually resist the action of acid as if covered by the etching-ground; but it is not so proper for the purpose of etching, as it cannot be so neatly removed by the point. Care must be taken in all cases not to put the acid on the plate until the varnish is dry. If this is not attended to, the varnish, instead of protecting the plate, will rise to the surface of the acid, and the plate will bite into holes in such portions as the varnish has been removed from. It may be easily known when the varnish is sufficiently dry, by breathing on it; if the

breath remains for some time on the surface, the acid may be applied with safety; but if it rapidly passes off, then it is not safe. It is a consideration in biting to produce a clear deep line. This desirable quality is more likely to be produced by pouring a depth of at least half an inch of acid on the plate, and by carefully removing, with a very soft feather, the small globules which will be seen to congregate on the surface of the plate. The biting is the most uncertain portion of the process of etching, and the most experienced are liable to fail. For general purposes, however, a very little practice will ensure success. When it is considered that the etching has been bit to a sufficient color, it is necessary to remove the bordering wax by heating the plate, and then clearing it with spirit of turpentine, and afterwards rubbing with oil and a soft rag; it will then be necessary to send to the copperplate printer for a proof.

The process of copperplate-printing is exactly the reverse of printing from woodcuts and type. In the latter the ink is passed from the surface of the block, etc., to the paper by means of pressure; in the former the impression is delivered from an incised line. In copperplate-printing the whole of the surface of the plate, and also the lines, are covered and filled with ink; the printer then (with the assistance of heat and whiting), by passing his hands gently and repeatedly over the surface of the plate, removes the ink from the entire surface, but leaves it in the lines or scratches. Damp paper is then passed through the rollers of the press, between the upper roller and the plate are several layers of cloth, and the ink from the lines is thus placed on the paper. If it is found, on examining the proof, that some portions of the etching are not sufficiently dark, the fault may be remedied by "rebiting."

The lines on the plate *must be most carefully* cleaned from all remains of printing ink, or any substance that would interfere with the proper application of the etching-ground or acid. It is best to wash the plate well with spirit of turpentine and a perfectly clean rag; then rub the lines and surface of the plate with spirit of turpentine and bread, and afterwards with spirit of turpentine and whiting; after that with whiting and bread. If any portions of whiting remain in the lines, it can be removed by wash-leather and soft bread: the object of all this care is to free the lines from any impediment to the action of the acid, and to enable the student to cover the *surface of the plate* with etching-ground, so that, the surface being protected from the action of the acid, but the *lines left unfilled*, the parts which are already sufficiently dark can be stopped up with varnish, and acid applied in the regular manner, and an increase of depth be got on any part of the plate that may be required. The principal things to be attended to in laying a rebiting ground are, that the lines shall be left free from etching-ground, and the surface completely covered; if this is not attended to, the acid will fill the parts of the plate that are not covered with varnish or ground with numerous small holes, which will certainly produce impure tints; this appearance is known among engravers by the name of foul biting. The dabber used to lay the etching-ground may be used for the rebiting-ground; but it is perhaps well not to apply so much heat, as the ground, if too thin, is liable to run into parts of the lines; this produces, perhaps, as ill an effect as foul biting, for if the acid is placed on such a ground, it will cause an unsteady or rotten appearance, by biting the lines which are clear to a greater thickness than others.

Considerable finish may also be got by using the "dry-point," which is nothing more than an etching-point made sharper than it is required for the purpose of etching; indeed, it is used for scratching such lines into the copper as will throw off an impression. On examining a line made with the dry-point, it will be found that the metal is not removed as if cut with a sharp graver, but merely pushed to one side; if this, which is called the burr, is allowed to remain, it will, by its roughness, collect the ink and form a blot on the impression. To remove this burr it is necessary to use the scraper in such a manner as not to drive the burr back

into the line, but rather to cut it from the sides in order that each line may be thoroughly clean.

The graver is used to increase the darkness of small portions, and is used in the hand as follows:

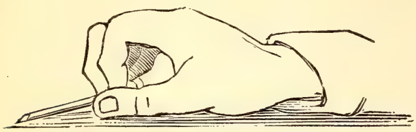

Fig. 13.

How to Make Emery Wheels.

BY W. B. HARRISON.

EMERY wheels should be made from clear, soft pine stuff that is well seasoned. By clear stuff is meant boards that are free from knots, cracks, or cross grain. These boards should be planed smooth on both sides, and then sawed into circular pieces a little larger than the finished wheel is to be. It is best to glue two or more of these circular pieces together, and glue them so that the grain of each piece will be at right angles to the one to which it is attached. If the stuff be inch thick when unplaned, it will be about seven-eighths of an inch thick when planed, and two of these pieces glued together will make a wheel of ample thickness for the use of the amateur mechanic.

If it be desired to make the wheel very strong, bore six or eight half-inch holes through the wheel, equi-distant from each other, within an inch or so of the periphery. Make pins of soft pine to fit these holes, coat them with glue, and drive them in snug, sawing off the projecting ends. The glued work must be thoroughly dry before advancing further. The next step is to form the discs into wheels, and the first proceeding is to make the hole to fit the spindle on which it is to revolve. To bore these holes with a bit or auger would, in all probability, result in a hole that would not be at a right angle with the side of the wheel. The proper way is to fasten the discs to the face-plate of a lathe, with screws inserted in holes from the back side the plate. When so fastened that it will revolve true, a gouge or narrow chisel can be used to cut the hole, and it can be made very nice and true. Take care to make it to fit the spindle on which it is to run. If an iron or metal bushing is to be inserted in the hole, turn out enough so that it will fit nicely in place before the wheel is removed from the face-plate.

The next step is to put it on the spindle on which it is to run, using a gouge to rough it into a circular form, and a chisel to make the surface smooth. The sides can now be turned up true. The periphery of the wheel must be covered with thick leather, and for this purpose the same kind of leather that belting is made of is generally used. Many mechanics get leather belting for this purpose. When all is ready, and a kettle of good glue prepared, lay one end of the leather on the circumference of the wheel and fasten it there with two or three shoe pegs. Insert the pegs in both leather and wheel by driving them into holes made for the purpose with a bradawl. Remove the leather with the pegs in it, spread the glue from the holes made for the pegs for a little distance in the direction in which the leather is to be put on, put the leather in place, inserting the pegs in the holes, and drive them home with a hammer. When glueing the leather, it is best to hold the wheel firmly in a vice, or stand, in such a manner that the leather can be pulled tight on the wheel as it is being glued. After pegging the edges of the leather as far as glued, at intervals of an inch or so, put on more glue, and so proceed until the end is reached, where it was first fastened; cut off the leather so that it will just meet this end; form a close joint; glue it well and securely peg it in place. Lay the wheel aside until the glue is thoroughly dry. The wheel may then be put on the spindle in the same way it was when turned, and the leather turned off true and smooth with a sharp gouge, finishing it with a sharp chisel.

Glue of only the best quality ought to be used in making emery wheels, and especially to fasten the emery to the leather surface. Prepare the glue as for glueing wood, and use it pretty hot, taking care that it is not too thick. The emery

to be applied is spread upon a level surface; a rod or stick is put through the hole in the wheel as a means of turning it; glue is then applied smoothly and evenly to the leather surface. Take an end of the stick or rod in each hand, with the wheel between them, and roll it in the emery until an even coating is retained on the glue-covered surface. Lay it aside to dry, being careful that nothing scratches or mars the freshly-coated surface. If the emery be applied warm by spreading it upon a warm board, or an iron plate also warmed, there will be no danger of the glue being chilled while the emery is applied, and a more lasting surface will be the result.

The grades of emery may range from No. 60 to 90, according to the work to be done. The coarser is used for cutting down a surface, and the finer for finishing and polishing.

In putting on the leather, some persons prefer to put the hair side of the leather to the wheel, giving as a reason that the flesh side is softer, and makes a more elastic wheel. In doing this the hair side must be thoroughly scraped before being glued to the wood. If it be desired to make a wheel elastic, two thicknesses of leather may be used, putting on one and letting it dry, turn it off, and put on a second one over the first; turn it off and coat with emery.

Wheels of hollow or round form can be easily made. Turn the wood to the required slope, and then go to a harness maker and have the leather rolled to the desired form by running it between the rolls that are used to shape leather in a hollow or round form for harness making. Apply the leather, and fasten to the wheel in the same manner as in making a flat wheel.

It is necessary to have emery wheels balanced. That is, one side must not be any heavier than the other. To ascertain where this balancing is required, put the wheel on the spindle on which it is to run, or on a tight-fitting wood rod inserted in the spindle hole. Have two straight edges of iron prepared, and fastened perfectly true and horizontal—wooden straight edges may be used, with the edges made pretty sharp, and these sharpened edges set uppermost. They must be placed parallel to one another, and at a distance apart to receive the wheel between them. On placing the wheel with its spindle on these straight edges, if one side be heavier than the other it will slowly revolve until this heavy side is at the bottom. Mark the side that is uppermost, bore a hole there, and drive in a rifle or pistol bullet. Try it again, and so continue until it will lie at rest on the straight edges. Where access can be had to an iron lathe bed, with the opening in the shear wide enough to receive the wheel, it is a very good substitute for the straight edges.

Wheels can also be covered with canvas or common sail cloth in place of leather. If several thicknesses are put on it will give an elastic wheel. Probably the most elastic wheel that can be made is by covering the wheel with stout cotton cloth, putting it on loosely, and stuffing cotton between the cloth and the wheel. Take care to put in the cotton evenly and alike all around. The cloth can be fastened to the wheel by using smooth-headed tacks, driven through it into the wheel at the sides near the periphery.

When the coating of emery wheels becomes worn by using, and is "dull" as it is termed, another coating may be put on over the first. A third may be put on over the second one. But when it gets uneven, it is best to soak off the old coatings with warm water. This may be done by putting a wet cloth around the glued surface, changing it occasionally until the glue can be scraped off. The scraping can be done with a knife that is not sharp enough to cut the leather. When dry apply a new coating. In places where many wheels are used, when the old coatings require to be removed they are revolved with the coated surface just touching the water. They can also be placed over a pan of water, and turned occasionally by hand until the surface is sufficiently softened to admit of its being scraped off.

—When the inscription on a coin is illegible, heat it gradually as hot as it will bear, and the letters will come out quite plainly.

Common Telescopes.—III.*

THE MODE OF OBSERVATION.

An ordinary telescope may be easily prepared for use: to fix it on its stand; to point it by means of the finder; to adjust the focus to the eye (remembering that different eyes require different adjustments), are processes scarcely requiring instruction. But many mistakes may be made in detail; and in this, as in everything else, there are various methods of doing the thing the wrong way. The present section will therefore consist of negative rather than positive directions, pointing out rather what should be avoided than what should be done.

1. Do not begin by fixing the telescope in a warm room and opening the window. A boarded floor is bad, as every movement of the observer is liable to produce a tremor; but the mixture of warm and cool currents at the window is worse; it is an artificial production of the fluttering and wavering which, as naturally existing in the atmosphere, are such an annoyance to astronomers. If a window must be used, let it be opened as long beforehand as may be, and let the object-glass be pushed as far as possible outside; there should be no fire in the room; and any other windows, as well as the door, should be shut before beginning to observe: the nuisance may thus be sometimes abated; but the right place is unquestionably out of doors.

2. Do not wipe an object-glass or metallic speculum more than can possibly be helped. Hard as the materials are, scratching is a very easy process; and the ultimate result of ordinary wiping may be seen in an old spectacle-glass held in the sunshine. The most valuable part of a good telescope deserves much more careful treatment; and, if protected from dust and damp, it will very seldom require to be touched. Nothing but great carelessness would expose it to dust; and the dewing of the surface may be almost always avoided. The object-glass or speculum, if kept in a cold place, should not be uncovered, if possible, in a warmer air till it has gained something of its temperature; and it must be invariably closed up in the air in which it has been used before it is removed in-doors; or, in either case, it may be dewed like a glass of cold water brought into a heated room. The object-glass, however, being much exposed to radiation, requires additional protection; and this may be easily contrived. A tube of tin, pasteboard, or very thin wood, such as is used for hat boxes, or, best of all, calico stiffened with shellac and varnished, fitting on to the place whence the brass cap has been removed, and three or four times longer than wide, will, in general, keep the object-glass bright. The "dew-cap" must fit tight enough to stand firm, or it will bend down and intercept the light; but not so tight as to cause trouble in removing it to put on the brass cap in the open air. It is better to blacken its interior—indeed, necessary, if of tin; this may be done with lamp-black mixed with size or varnish, so as neither to show a gloss nor rub off; or a piece of black cloth or velvet may be glued or pasted inside it. A lining of blotting-paper is serviceable in heavy dew. A dew-cap on the finder will often save much trouble. Should it be necessary to leave the telescope for some time in the cold, a clean handkerchief thrown over the end of the dew-cap will be a complete safeguard. Should an object-glass or speculum become damp after all, do not close it up in that state; if the cloud of dew is very slight, it may quite disappear in a warm room, especially if exposed to a fire; if dense, however, it may leave a stain which ought to be quickly removed, as well as any little specks of dirt or dulness which will form, one knows not how. To do this, dust the dried surface first with a soft camel's hair pencil or varnishing brush, which will remove loose particles; then use, very cautiously, a very soft and even piece of chamois leather, which has not been employed for any other purpose, and must be always kept in a wide-mouthed stoppered bottle or wrapped up from dust; or a very soft silk handkerchief (which Lassell uses for glass) preserved with similar care. But the

*From advance sheets of "Webb's Celestial Objects for Common Telescopes."

wiping must be as gentle as possible; rubbing is inadmissable in any case. Proctor advises sweeping from a small space near the edge as a centre. Any refractory stains may be breathed upon, or touched with pure alcohol, and wiped till dry; but if the glass has become discolored, we must put up with the defect; and care should be taken not to mistake specks in the substance of the glass for foreign matters lodged on its surface. A slight tarnish may frequently be removed from a metallic speculum by lemon-juice, or a solution of citric acid, or spirit of hartshorn, carefully wiped off in a short time; if this does not restore its brightness, it is better to leave it alone; a slight loss of light is not so great an injury as would result from strong friction. The taking out or replacing of an object-glass or mirror is a delicate operation, and hurry or carelessness may easily make it a very dangerous one; speculum metal is nearly as brittle as glass: but this material is rapidly going out of use, from the superiority of the silver-on-glass mirrors, which are now becoming appreciated as they deserve. The management of these need not be described here, as special instructions should always accompany them, such as will be found in Browing's "Plea for Reflectors," or Calver's "Hints for Reflecting Telescopes."

Dimness of vision often results from damp on the eye-lens. This will rapidly disappear, without wiping, in a warmer temperature. If the finder does not act well, this may be suspected to be the cause. For these and many other reasons, a small lamp, the light of which can be concealed at pleasure, is a convenient adjunct to the telescope; any glass surface held at a safe height over it will speedily be cleared of moisture. A ground or papered glass front to a lamp is advantageous for reading.

Eye-piece lenses require occasional wiping; the leather may be pressed to their edges with a bit of soft wood. A piece of blotting-paper rolled to a point, and aided by breathing, answers perfectly. Their flat faces are easily scratched if laid downwards on a table. The screws demand very gentle usage: a previous turn backwards, before screwing in, causes the thread to fall with a snap into its place.

Hand-Turning.

I NEED scarcely insist on the actual necessity of everyone learning, first of all, to turn by hand. I have found the want of knowledge of the first rudiments of turning very much against the progress of anyone desirious of becoming an efficient. I know very many amateurs who can ornament a box well enough, for example—equal, in fact, to anyone who does such things professionally; but if they had to turn the box for themselves, it is certain it would not be ornamented at all. Therefore it is an absolute necessity for learners to begin at the beginning, and progress gradually to the various grades. Authors generally begin with soft-wood turning, and represent it as the most easy to accomplish. That it should be the first thing commenced on, I grant; but that it is the more easily acquired I do not admit. This, however, is a matter of opinion, and needs no discussion here; so to the point. In beginning, as a tyro, all that will be necessary is a plain lathe, the size or height of centre of which is of no consequence—but I should advise a 5 inch centre lathe—and the tools required will be simply a gouge, chisel, and parting-tool. The latter most people who essay to write upon this subject seem to ignore. I admit that a good deal of work can be detached with the edge of the chisel, but still the parting-tool is a necessary adjunct, and will be wanted. The wood I should recommend will be any soft wood, such as pine, mahogany, tulip, king, and many others of this class. Having arranged the tools and selected the materials, we will begin by placing upon the lathe the prong-chuck, which is made of metal, with a steel prong screwed into it. This part is made with a centre, and the flats filed down to the size of the largest end of the point, each side being then filed like a wedge, the bevel being, of course, to the rear. This, it will be obvious, will not allow of the two face-lines being diametrically opposite, as would be the case if

the prong were filed like a wedge, as in days gone by. It is a rule with some makers to have a gap each side of the point; but this is more to save labor than for any other purpose. Although the point is turned perfectly true, for the purpose of enabling the turner to place the work back, having removed it, it is the best plan to mark one side of the chuck, and so be certain that your work is running exactly as it was before taken from the lathe. Having found the centre of the wood and made a hole in the same, it may be driven into the prong by the aid of a hammer or mallet, care being taken not to split it. The popet-head centre, or, as it is commonly called, the back-centre, must be brought into use to support the end nearest to it. It is an old saying, and true, that position is everything, and it applies to turners, as in every other case; but a too-carefully studied pose may cause great discomfort to the operator. Therefore, provided it is not absolutely awkward, the position one feels most at home in will be found to be the most advantageous.

Should the wood be a very rough piece, or, say square, it will be advisable to take the corners off with an axe. The T-rest will be set rather higher than the centre. The gouge should have a long handle about 10 in., and the tool itself 8 in. This will be the proportion of what is called a three-quarter gouge. In the commencement, it should be held with a firm grip in the right hand, the left being placed on the top over the T-rest. If the left hand is in its proper position, which with a little practice it will assume, it will, by working the right hand from right to left, form a centre, so to speak. Before attempting to cut the wood, it would be as well to practice this movement for a short time. It must not be taken for granted that by moving the gouge as I have described, it will describe a curve; this will be obviated by raising the right hand gradually as it is worked either side of the so-formed centre, and it will, of course, only turn as much of the wood as the movement will allow; it must be then moved along the T-rest. I have turned a cylinder without the use of any other tool. It has been suggested by more than one author that the tyro's aim should be to turn a long cylinder, after the fashion of a ruler; but I should rather advise a novice not to set his mind upon accomplishing this feat, as not many can do it at all; by this I mean a cylinder perfect in every respect. The first day's work will be quite satisfactory if the pupil can rough-off a piece of wood, turning it fairly true, and without its flying out of the lathe several times. The second attempt should be diversified by the use of the chisel; but before taking advantage of this latter tool to smooth the work, endeavor to get it as smooth as possible with the former. The chisel is a flat tool, in some respects similar to others of the same name, but ground to a different form, being beveled on both edges and obliquely to the sides; the angle from side to side about 35 degrees. In using this tool, it is the centre of the cutting-edge that must be made the cutting part, except when shaping curves, or parting off any one part from the other. When passing it along a cylinder, it will require very great care to keep the corners from touching; if they do, it will run into the work after the manner of a quick screw, and do considerable damage—in some cases irreparable mischief. It must be held much after the manner of the gouge, and nothing but practice will overcome its difficulties.

Having gone sufficiently far with the cylinder to become tired of the same thing, we may now essay to turn various other forms, for example, an egg-cup. The convex part it will be obvious, must bring into use the chisel. The concave, or foot, will necessitate the gouge; for such work smaller tools will be better, and it will be advisable to have a selection, three or four of each—gouges and chisels, choosing those for use which appear to be the handiest. Here, again, there is no law as to size of the tool to be used, as some would prefer half an inch, others a three-eighth tool for the same purpose; therefore, as long as it will effect the purpose, that which is the most convenient should be chosen.—*J. H. Evans in English Mechanic.*

(To be continued.)

The Meaning of Dreams.

Lively dreams are, in general, a sign of excitement of nervous action; soft dreams, a sign of slight irritation of the brain, often, in nervous fevers, announcing the approach of a favorable crisis. Frightful dreams are a sign of determination of blood to the head. Dreams about fire are, in women, signs of impending hæmorrhage. Dreams about blood and red objects are signs of inflammatory conditions. Dreams about rain and water are often signs of diseased mucous membrane and dropsy. Dreams in which the patient sees any part of the body especially suffering, indicate disease in that part. Dreams about death often precede apoplexy, which is connected with determination of blood to the head. The nightmare (*incubus ephialtes*) with great sensitiveness, is a sign of determination of blood to the chest. "To these," says Baron Von Fechterleben, "we may add that dreams of dogs, after the bite of a mad dog, often precede the appearance of hydrophobia, but may be only the consequences of an excited imagination." Dr. Forbes Winslow quotes several cases in which dreams are said to have been prognostic: Arnaud de Villeneuve dreamed one night that a black cat bit him on the arm. The next day an anthrax appeared on the part bitten. A patient of Galen's dreamed that one of his limbs was changed to stone. Some days after his leg was paralyzed. Hippocrates remarks that dreams in which one sees black spectres are a bad omen.—*Dr. Hammond in Druggists' Circular.*

Dressing the Points of Draughting Pens.

The ability to sharpen a draughting pen and put it in complete order depends, in some measure, upon the skill and experience of the draughtsman, and the previous condition of the pen. If the pen has been worn too much, it would be much better to throw it aside and procure a new one. If it has not been worn or rusted to any very considerable extent, it may be easily sharpened as follows: In the first place, screw the blades up into contact and pass along the surface of an oil stone, turning upon the point in a directly perpendicular plane until the two plates acquire an identical profile. Next, unscrew the blades and examine them, in order to ascertain the parts of unequal thickness around the nib; then the blades are to be laid separately upon their backs on the stone and rubbed down at the points until they are brought up to an edge of uniform fineness. At this stage it is advisable to screw them together again and pass them once or twice more over the stone, in order to bring up any fault. After this they may be also touched on the outer and inner side to remove barbs or feather edge. Careful inspection of the instrument during this process, and the exercise of careful judgment, will enable any one to put a pair of draughting pens in good condition, provided, as we said above, they are not too badly rusted or worn out.—*Metal Worker.*

Coppering and Bronzing Zinc.

The following recipes for coppering and bronzing zinc are said to produce quite beautiful results: Prepare a solution of fifteen parts of blue vitriol and one of nineteen parts of cyanide of potassium, then mix both solutions together. Incorporate this liquid well with one hundred and sixty parts of pipe clay, and rub the resulting semi-fluid mass, by means of a linen rag, on the previously cleaned object. For bronzing, take fifteen parts of verdigris, nineteen of cream of tartar, and thirty parts of crystallized soda, reduce them to powder, and dissolve them in the necessary amount of water. Mix this liquid together with one hundred and sixty parts of pipe-clay, and proceed as above directed. Another process is as follows: Take fifteen grammes of blue vitrol, twenty of calcined soda, mix them well with thirty-two cubic centimetres of glycerine, and mix the paste obtained with eighty grammes of pipe-clay. It is then ready to be applied as before stated.

The Word "Gramme."

The general adoption of the French weights and measures by scientific writers in all parts of the world, has rendered the use of the word "gramme" of constant occurrence. We are extremely sorry to see that some of the young chemical writers in England have lately followed the American example of spelling the word "gram." It has been long ago observed that American writers have little respect for literary laws of any kind, and if their example were universally followed, philology and etymology, which are so useful to the historian and to the antiquary, would soon be things of the past. But in the present case the abbreviation of the word gramme is not only an example of needless bad taste, but it is also a dangerous vulgarity. More than once we have seen the most important errors committed in medical periodicals by confusing the said abbreviation with our English word *grain.* As there are fifteen English grains in a gramme, our readers will at once perceive the necessity of avoiding such dangerous confusion in medical and scientific literature by adhering to proper spelling.—*The Monthly Magazine.*

EXCHANGES.

Only those who are *yearly* subscribers, and whose names are entered on our books have the privilege of inserting exchanges.

Exchanges must be on separate slips of paper or postal cards. If mixed with business letters or cards they cannot be used.

Exchanges must not exceed thirty words.

Buying and selling belong to the advertising department.

We reserve the right to omit the exchange column, when we have not room for it, and the amount of space at our disposal will regulate the number of insertions given to each *exchange*, the preference being always given to those who have not previously used our columns.

To exchange, for engine or offers, a pair of Bliss Telephones and 200 feet of copper wire. J. W. Grant, 402 Broad St., Newark, N. J.

To exchange, a 2½ octave chromatic xylophone for microscope, microscopical apparatus, scientific books, or offers. J. E. Moore, Box 81, Newcastle, Ind.

I have McAllister's Naturalists' Microscope, with achromatic triplet objectives, used only 2 months, cost $12.00. I wish to exchange for an inch or 2-3 inch objective. Address, with particulars, F. F. Colwell, Urbana, Champaign Co., O.

To exchange for offers; a small lot of microscopic mounting apparatus. List on application to J. N. B., Box 1468, N. Y.

To exchange, books and Young Scientist, and trinkets, for other books, revolver, or stylographic pen. Frank Bicknell, Humboldt, Iowa.

Ancient petrified grain, Indian pottery, birds eggs, papers, magazines, Confederate money, fossils, minerals, to exchange for arrow-heads, Indian relics, Confederate, Continental, and other paper money. Fred T. Brinkerhoff, Box 347, Neenah, Wis.

Minerals, tricks, copper coins, book on pigeons and rabbits, Wilson School History, for book on experiments, or specimens, minerals, stamps or coins. P. R. Bradley, Box 305, Dunkirk, N. Y.

Wanted, a second-hand screw cutting foot lathe, must be in good condition; state what is wanted in exchange, also size and make of lathe. G. A. Clark, Castalia, Iowa.

To exchange, minerals, shells, fossil shells, birds eggs, etc., for minerals, shells, fossils, stuffed birds, birds eggs, and books. U. S. Grant, Des Moines, Iowa.

Wanted, botanical correspondents for the coming season, also amateur correspondents in chemistry. L, Box 70, East Templeton, Wov. Co., Mass.

Wanted, to exchange a well-equipped job printing outfit, for books or offers. Frank A. Niblack, Rockport, Ind.

Will exchange for Vol. 2 of the Young Scientist, instructive books bound in cloth to the value of $1.50. Chas. H. Williamson, 293 Eckford St., Greenpoint, Brooklyn, N. Y.

I have a new Munsen's battery, large size, which I wish to exchange for a good revolver or offers. Robt. T. Boyle, 351 West 83d St., New York.

Hair of American deer to exchange for diatoms, foraminifera, or other material. W. H. Osborn, Chardon, Ohio.

To exchange, full instruction in short-hand writing, and birds eggs, for birds eggs, postage stamps, or offers. M. F. E., 51 Spencer St., Albany, N. Y.

Wanted, specimens in geology, entomology, oology, etc., for those in other localities, also coins and a charm microscope (magnifies 1,000 times) for one having a different view. J. H. Jones, Frankfort, N. Y.

"History of Our Country," by Lossing, in six parts, price $15, to exchange for printing press or offers. Frank Chandler, Waverley, Mass.

Fine Devonian and Carb. fossils for others, especially cretaceous fossils, scientific books or papers; Pitman's short-hand works for books or offers. A. Stapleton, East Point, Tioga Co., Penn.

Wanted, scientific books and apparatus; send lists and say what is wanted in exchange. Ewing McLean, Greencastle, Ind.

Send for exchange list of insects, especially Coleoptera and Lepidoptera. Philip Laurent, 621 Marshall St., Philadelphia, Pa.

For printing press or offers, achromatic telescope, $8.50; microscope, $5; set drawing instruments, $3; revolver, $3; Phrenological Journal, $2.50; books, 12 plays, farces, dramas, burlesques, etc., $1.80. F. E. Payne, Alma, Mich.

One pair 3 lb Indian clubs, one scroll saw, one pocket lantern, and a large number of books, for magic lantern, pair telephones, photographic camera, or offers. Thos. A. Black, Lock Box 678, Scranton, Pa.

For exchange, pocket lantern and instruction books for cornet and clarionet; wanted History of the "Franco-Prussian War," and the "Lost Cause." C. W. Hughes, Shreve, Wayne Co., Ohio.

I have Brown's heavy scroll saw attachment, worth $6, which I wish to exchange for a lathe chuck or offers. C. B. Russell, Waterbury Centre, Vt.

Will exchange magnets, electric battery, as good as new, cost £3 in England, for plating battery and materials, or offers. F. Whitehead, Box 55, St. Augustine, Fla.

American and foreign coins to exchange; state what you have. W. J. Allen, 126 Twenty-third Street, Brooklyn, N. Y.

To exchange, fine imported game fowls of the best strain for Fleetwood scroll saw, compound microscope, telescope, magic lantern, shot gun, or offers. E. Alexander, Johnstown, Fulton Co., N. Y. Box 47.

J. T. Bell, Franklin, Pa., has set of ivory chessmen, German flute, six extra keys, value $12, books, etc., to exchange for magic lantern, music box, guns, revolvers, or offers.

Birds eggs and arrow-heads to exchange for fossils and minerals, and birds eggs; send for my list. Clement G. Burns, Salem, Col. Co., Ohio.

Minerals (zeolites, etc.), to exchange for other minerals; state what specimens you have to exchange. H. L. Clapp, 35 West Cottage St., Roxbury, Mass.

Type, in exchange for curiosities, fossils, etc. Geo. K. Fischer, 729 North 6th St., Philadelphia, Pa.

I have some stamps which I would like to trade for stuffed birds, birds eggs and nests; I am also open to an offer; send for list of stamps. A. G. G., Box 26, Summit, New Jersey.

SCIENCE IS KNOWLEDGE.

KNOWLEDGE IS POWER.

A PRACTICAL JOURNAL OF

HOME ARTS.

VOL. IV. NEW YORK, AUGUST, 1881. No. 9.

Cutting Glass With a Hot Iron.

CERTAIN tramps, who are "hard up," periodically travel through the country, selling, as a great secret, directions for the old process of cutting glass with a red-hot iron. The method is very simple, and to those who have failed with the recipes usually published (strings wet with turpentine and set on fire; friction with strings, etc.) the results are rather surprising. We have never found any difficulty in cutting off broken flasks so as to make dishes, or to carry a cut spirally round a long bottle so as to cut it into the form of a corkscrew. And, by the way, when so cut, glass exhibits considerable elasticity, and the spiral may be elongated like a ringlet. The process, as we have just said, is very simple. The iron rod (a common poker answers very well) should be somewhat pointed, and the line along which the cut is to be made should be marked by chalk or by pasting a thin strip of paper alongside of it; then make a file mark to commence the cut; apply the hot iron and a crack will start; and this crack will follow the iron wherever we choose to lead it. In this way jars are easily made out of old bottles, and broken vessels of different kinds may be cut up into new forms. Flat glass may also be cut into the most intricate and elegant forms.

Sometimes it is not convenient to use a red-hot iron, and some persons fail in its use. In such cases carbon pencils or pastils may be used. They are made according to different recipes, of which we give three:

1. Dissolve 100 parts of gum arabic in 240 parts of water, and mix the solution with a paste prepared by triturating 40 parts of powdered tragacanth with 640 parts of hot water. Then, having dissolved 20 parts of storax and 20 parts of benzoin in 90 parts of alcohol (0·830), strain the latter solution and add it to the mixed mucilage. Finally mix the whole intimately with 240 to 280 parts of powdered charcoal, so as to

be uniform throughout. The charcoal should previously be passed through a fine sieve. The doughy mass is cut into suitable pieces, which are rolled between two boards dusted over with coal-dust, until cylindrical strips about 1 centimetre in thickness are formed, which are allowed to dry slowly between blotting-paper. When using them, one end is pointed like a lead pencil, and, after having previously made a scratch in the glass with a file or diamond, the heated and glowing end of the pencil is carried along the line in which the glass is intended to be fractured.

2. Dissolve 8 to 10 parts of tragacanth in about 100 parts of hot water, add to the mixture, under stirring, 30 parts of acetate of lead and 60 parts of finely-sifted beach-wood charcoal, and proceed as in the previous formula.

3. Sticks of soft wood (willow or poplar), of about the thickness of a finger, which must be thoroughly dry, are immersed for about one week in a concentrated solution of acetate of lead, after which they are again dried. When ignited these sticks burn like glazier's charcoal.

The first formula is that of Berzelius, and yields the best product, as it burns much slower than the others. These pastils maintain a more uniform heat than a hot iron, which is constantly getting cold.

Hand-Turning.—II.

(*Continued from page* 90.)

OUR remarks so far refer to such turning as may be accomplished between the centres of the lathe cylinders. We will now proceed to the turning of such articles as require to be turned out after the fashion of a bowl. The work must be chucked in a different form altogether; in some cases on a worm chuck, in others a cup-chuck may be more convenient. Now, to turn the face of a large diameter is quite a different thing from turning a cylinder; but having practiced the latter, the hand will have become used to the holding of the gouge, and the difference in position and angle of the tool necessary will, to a certain extent, suggest itself.

The T-rest will be now more convenient, if lowered, to allow of the cutting edge of the tool being brought nearly to the centre; the same motion as derived by the left hand being on the top of the tool and the right holding the handle, as in turning between centres, will now be obtained, only it will be applied to the surface. In turning out a bowl, for instance, the gouge must be turned on to its side until the left side becomes the upper part, and, according to the curve and depth of bowl required, the right hand must be moved to form the desired sweeep, and at the same time the gouge allowed to slide gradually through the left hand, which hand, although released to allow of this movement, must still retain sufficient hold, and not allow the tool to go where it is not wanted. I dare say, however, that it will insist upon taking a different course to that actually desired in the first few trials. I think we may turn our attention to the production of something useful in the shape of a box for some actual purpose, viz., for holding string. I start with this because it will give opportunity for further advance, as it will require several chuckings. Before beginning this, I think a few hours at screw-cutting will be of great service. Soft wood screws are generally made with what are termed screw boxes, which are to be had at all the tool shops, and are made from a very small size to the size of bench screws, about 2½ or 3 in. diameter. These, however, will not serve the purpose now requisite; therefore, a little practice and patience must be used, and I think it will be overcome. To begin with, when about to make anything that will require a screw, a wood of closer grain will be better, and I should choose a piece of good, sound, well-seasoned box-wood. In what we call striking a screw, the front edge of the wood should be rounded off, the screw tool held in right hand, with the thumb of left hand on the top over the T-rest, the hand itself passed round the body of the rest, and held firmly. A circular motion must be given with the right hand, and the centre part of the chaser will be that which first comes in contact with the work. It will only be after several trials that anything

resembling the run of a screw will appear; but by practice it will show itself, and must be then followed on to the part of the work where it is required. In case of a mishap, always leave the material both longer and larger in diameter than it will be wanted when finished, as the lead of a screw can generally be carried any length that may be required. Having practiced the chasing of an outside or male thread, we must turn our attention to the inside or female screw; the principle for this is just the same as in the former, the front of the wood must be rounded off, and the screw tool passed in and out, with a slight movement of the right hand, which must be worked from right to left, until the lead is obtained. In making a box make the lid first, and to do this, the piece of wood of which the whole thing is to be manufactured from should be carefully turned by aid of the prong chuck, to fit into one of the metal cup chucks, the size of course, being chosen to suit the material. The fitting should be slightly taper, and it can then be driven tightly in. Practically, the wood must not bottom—that is, a space between it and the end of the chuck is always left. It is as well to drive the wood into the chuck by placing it on a solid bench, and not to commence hitting it when on the mandril, although if not true, it may be corrected when in its place. The material now being properly held, the first step will be to determine the depth of the lid, and set the turner's square to it; then turn it out, taking care to have the inner surface perfectly flat; this done, take what is termed a hook tool, that is, a small tool turned at the end to a right angle, and rounded at the end. Insert this in the end, where the screw is to terminate, for the purpose of allowing the chaser to finish the screw without forming a ridge, or an unevenness, which will prevent the male screw going home to its place; having gone so far, the lid must be parted from the bottom, and it will be seen at a glance that the remaining portion, forming the bottom of the box, will act as a chuck upon which to finish the lid. The inside of the lower part can now be turned to its desired dimensions, and the outside screwed to fit the top; when this is done, the whole of the box can be turned off in one cut, and if the screws are properly fitted, it ought to be difficult to find the place where the two parts join. The outer shape may be ornamented by the application of a smaller chisel, and very pretty plain mouldings accomplished. I need scarcely mention that where large quantities of any special things of one particular shape are required, that a moulding-tool is made to the shape, and this, by being simply inserted, forms at once the shape, and insures their cut being exactly alike. I will now proceed a step further, and suggest that the next piece of work attempted should be what, for want of a better title, we will call a puzzle-box. This may sound somewhat *infra dig.*, but it will bear out its name in two senses: first, it will be a more difficult thing than might be imagined; secondly, if properly made, it will certainly puzzle anyone to extract its contents without being told how to do it. This box, in the first instance, shall take the shape of a ball—about the dimensions of a full-size billiard-ball will suffice. This, in itself, is no easy matter to accomplish, and it must be chucked several times in order to obtain a sphere; and if an opportunity should arise, I would ask anyone about to turn such an article to watch a billiard-ball turner for a little while, for although I am endeavoring to give all the information I can upon this subject, I candidly confess that a few hours' practical tuition is worth any amount of literature upon the same topic. We will presume, however, that the ball is completed. It must be chucked firmly, and a hole, slightly taper, turned right through it, about 1 in. diameter at the smallest end, and about 1-16th in. larger at the mouth. There is no rule for the sizes, and it matters little what they are. Having turned this perfectly straight and smooth, put it on one side, and turn a piece to fit it exactly. When this is done, the second part must be formed into a box, after the manner previously described. When this is so far finished, the box part is fitted into its place, and must be all turned off to the sphere as if it consisted of one piece only.

It will form a capital thing for practice, and, if well executed, will elicit great praise from any one who can appreciate good work. The next lesson will be to turn something in the shape of a vase from a pattern: the bare outline only will answer. It should be copied to such a nicety that it will be difficult to distinguish which is the original. For this purpose measuring instruments will be most essential, such as calipers, turner's square, before-mentioned, inside callipers, etc., etc. The production of two pieces of turning, one the facsimile of the other, is always considered a great achievement, and it should be practiced until overcome; and it may be taken for granted that the person who accomplishes such a thing is really a good turner. Having reached this stage of perfection, there is no reason why the slide-rest should not be now brought into use, although for soft-wood turning such an instrument is seldom used; but we will go a step beyond this material and try some of a closer grain and harder substance. Whatever the wood may be, if the slide-rest is to be employed, a gouge-cutter bar should be the tool used for roughing down the material. Now, with the assistance of both slide-rest and cutter-bar, the difficulty of turning a cylinder, whether it is for a ruler or any other purpose, will be reduced to a minimum, and will require very little practice; it will also become an easy matter to shape up whatever may be wanted, by using both handles of the slide-rest simultaneously. For turning out a deep recess, the slide-rest will be found a most useful tool, and will enable the operator to accomplish the work with more speed.

I think it will be useful to give a few hints upon making boxwood or other chucks. To make these, two taps and a chase will be required, also a half-round bit, the latter being made to the exact size of the bottom of the thread, and the taper or marking-off tap should be made to just enter and be taper. The thread must be cut up sharp at the point as well as the rear, because if filed off as taper taps generally are, the point will be flat instead of sharp, consequently the chaser will not readily find its proper starting point, the marking being a broad instead of a fine cut. Having bored the hole with the standard bit, mark off the thread with the taper, or first tap, and then chase the screw until the full-size tap will just enter, and then gently force the plug through the hole, and the tap being a counterpart of the mandril nose, made to cut, the chucks will fit on their place without further trouble. This is the manner in which amateurs should accomplish this most useful branch of turning. We, in the manufacture of best lathes, always cut the chucks in a self-acting lathe, but as few have the advantage of these useful, although expensive, tools, the above-mentioned plan is the handiest way to overcome the difficulty. Some workmen can strike off the screw without the aid of taps and bit, but unless great proficiency has been obtained, I should advise the use of the means described. A very useful addition to the lathe, especially for any one who is at all fond of carpenter or joiner's work, will be, what is termed, a pad chuck. This is made exactly after the fashion of that part of a carpenter's brace into which the centre bits fit, and they are held in their place by a spring and catch. The spring being pressed down, the tools are easily removed. For boring large holes in flat surfaces, this chuck will be extremely handy.

It remains at present only to say that it will be futile to anticipate reaching a high standard of perfection in the art, unless the rudiments are thoroughly learnt and practiced before venturing upon anything approaching ornamental work that requires special tools.—*J. H. Evans in English Mechanic.*

TEA TWO HUNDRED YEARS AGO.—The London *Gazette* of December 16, 1680, has the following: "These are to give notice to persons of quality that a small parcel of most excellent tea is by accident fallen into the hands of a private person to be sold; but, that none may be disappointed, the lowest price is 30 shillings a pound, and not any to be sold under a pound weight, for which they are desired to bring a convenient box. Inquire at Mr. Thos. Eagle's, at the King's Head, in St. James' Market."

Three Amateur Workers—and What They Did—XI.

BY FRED. T. HODGSON.

WE find Mr. Carpenter and the boys in their snug shop hard at work preparing the various pieces for the umbrella stand. It was decided to make it of ash—not because that wood was any better for the purpose than oak, walnut, or chestnut, but because it happened to be the most convenient to obtain in their locality. Two posts, 2 feet 3¾ inches long by 1½ x 1¼ inches, were prepared, and made straight, square, and true. Two pieces of stuff, ¾ of an inch thick, and 8 inches wide, and 2 feet 3¾ inches long, were prepared, being cut out at the top, same as shown at Fig. 41, with the scroll saw. It will be noticed that centre beads are run down at regular distances where each ornament starts at the top of the back. A tongue is wrought on one edge of each of these pieces. These tongues are designed to fit in a corresponding groove in the posts, and are there glued solid and firm. The pieces are also glued together at the central joint.

The little turned knobs at the top of the posts are two inches and a quarter long to the shoulders, and were obtained at the nearest turning shop for a few cents. A pin, about half an inch in diameter, was left on the lower end of each ornament, and a corresponding hole was bored in the top end of each post. In this hole the pin on the end of knob was inserted and glued. The rod running across the stand is turned out of stuff about one inch square, and is sixteen inches between the shoulders. Pins about ⅝ in diameter are turned on each end; these are glued into holes made in the brackets. The little knobs on the outside also have pins turned on them. They also are glued into the brackets on the outside. The posts are chamfered on the front corners, that is, the sharp corners or arrises are taken off about a quarter of an inch each way.

The top brackets are 9½ inches at their greatest width, and they run down the posts exactly one foot; they are made of seven-eighths stuff, and are fastened to the posts with screws and glue. The screws are two inches long, and are run through the posts from the back, the thread of the screws going into the back edges of the brackets.

The lower brackets are made of stuff the same thickness as the upper ones, and are 7 inches wide at their greatest width, and run up the posts 5¼ inches; screws and glue are used to fasten them to the posts and shelf, same as the upper brackets.

The shelf is 8¼ inches wide, and 18¼ inches long; it is chamfered on the front and two ends on the top corners. It must be notched out where it fits round the posts, so as to let the back edge fit snug against the back-board. The back-board is fastened to the edge of shelf with 1½ inch screws, about five of them being employed for that purpose. The under side of shelf is set up just two inches from the lower end of the posts, thus making the ends of the posts answer for two back feet, while the two front ones are formed out of stuff the same thickness as the brackets. The feet measure two inches from the shelf, to which they are fastened by screws and pins to the floor line or bottom.

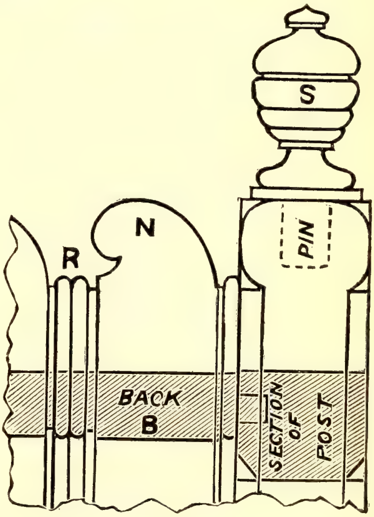

Fig. 42.

Fig. 42 shows the end of the post with the turned ornament, s, on the top. The dotted lines show the pin on the end of

the ornament, and the mode of fastening it to the top of the post. A shows a section of the post with the groove in it to receive the back; it also shows the "chamfers" on the two front corners. B shows a section of the back, showing the tongue that fits into the groove in the post; the centre beads and quirks are also shown. At N is shown the form of finish at the top of back. These forms are made with the aid

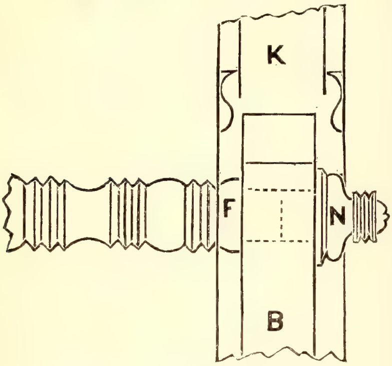

Fig. 43.

of the scroll saw. R shows how the beads are finished at the top of the back between the large ornaments. Mr. Carpenter procured a quarter-inch centre-bead plane, for working the beads on the surface, at a cost of seventy-five cents, and Fred found no difficulty in applying it. The tops of

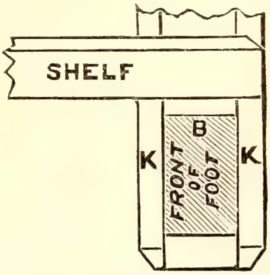

Fig. 44.

the beads, across the end wood were worked out with a sharp chisel, after being sawed down with a fine saw.

Fig. 43 shows a portion of the post K, and a part of the bracket B, with the turned rod F, and the ornament N. The dotted lines show the pins both on the rod and ornament. It is not necessary that the rod be turned exactly the shape as shown, but it is imperative that the distance between the shoulders thereof be precisely as given.

Fig. 44 shows a portion of the front edge of shelf with chamfer on top corner. B shows front edge of foot, and K K shows a part of the post.

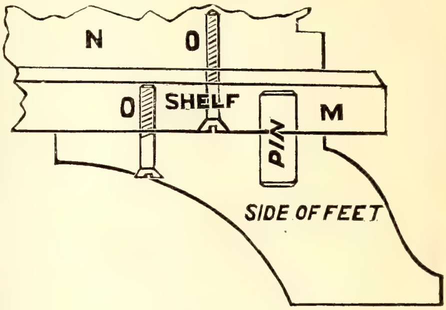

Fig. 45.

Fig. 45 shows the shape of the foot, and the method of fastening it to the shelf M. The screw O, goes through the shelf M, into the bracket N, the head being covered by the edge of the foot.

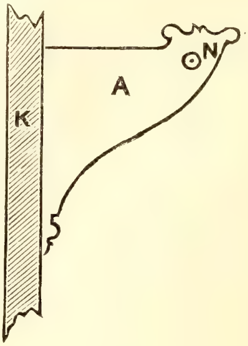

Fig. 46.

Fig. 46 shows the post K, and the shape of the upper bracket A. The ornament, N, is glued in place, and the centre of it is exactly 7⅝ inch from the post. At Fig. 47 the shape of the lower bracket N, that fastens on the shelf M, and the post K, is shown. The method of fastening the bracket to shelf and post, and the end of shelf, are also shown.

Everything being ready, and the glue made good and hot, Fred and Ellwood, under the direction of their father, began

to put the work together, an undertaking that the boys had looked forward to with considerable anxiety for some time. The back was glued together, and the posts driven on to the edges of the back; next, the turned rod was glued into the upper

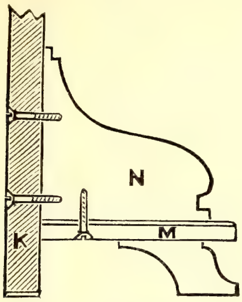

Fig. 47.

brackets, and the latter were then screwed and glued to the posts. Then the shelf was fastened from the back, and the lower brackets and feet attached and properly fastened; and lastly, the turned ornaments were glued and then driven in their places, and for the first time the "Umbrella Stand" stood on its feet. To Jessie, who had watched the operation throughout, the result seemed like a piece of magic, and her eyes fairly gleamed with astonishment. The boys, too, felt as though they had achieved something wonderful, and felt more important than ever they did before. Of course Mamma had to be informed of the result, and Jessie performed that duty almost instanter.

"Now, boys," said Mr. Carpenter, "we will let our work stand until to-morrow night, before we do any more to it, and by that time the glue will be 'set,' and then we will finish it; so let us leave work for to-night."

Common Telescopes.—IV.*

THE MODE OF OBSERVATION.

BRASS-WORK should not be rubbed with polishing powder, which might injure the lacquering; ammonia is preferable.

3. If the telescope does not seem altogether right, notwithstanding all the pains you can take in bringing it to focus, do not meddle with screws or adjustments, unless you thoroughly understand the construction, or can obtain good directions. In most cases a screw driver is a dangerous tool in inexperienced hands.

4. Do not use any part of a telescope or stand roughly, or expose it to any blow or strain. It is a delicate instrument, and well deserves careful preservation.

5. Do not spare trouble in adjusting the focus. It is well known that different eyes require a change, sometimes a great one; and the same observer's focus is not invariable, being affected by the temperature of the tube and the state of the eye, the adjustment of which, as Dawes has pointed out, shortens with intense gazing, and is apt to vary with the relative brightnesses of objects, besides being, to a certain extent, under the observer's control.

6. Do not over-press magnifying power. Schroter long ago warned observers against this natural practice, which is likely to lead beginners into mistakes. A certain proportion of *light* to *size* in the image is essential to distinctness; and though by using a deeper eye-piece we can readily enlarge the size, we cannot increase the light so long as the aperture is unchanged; while by higher magnifying we make the inevitable imperfection of the telescope and the atmosphere more visible. Hence the picture becomes dim and indistinct beyond a certain amount of power, varying with the brightness of the object, the goodness of the telescope, and the steadiness of the air. Comets and nebulæ, generally speaking, will bear but little magnifying. For the moon and planets, the power should be high enough (if the weather is suitable) to take off the glare, low enough to preserve sufficient brightness and sharpness; the latter condition being preserved, minute details are likely to come out better with an increase of power. Stars bear much more magnifying, from their intrinsic brilliancy; and they are enlarged very slightly in proportion; their images ought never, with any power, to exceed the dimensions of minute discs—*spurious discs*, as they are termed, arising from the undulatory nature of

*From advance sheets of "Webb's Celestial Objects for Common Telescopes."

light, and usually smallest in the best telescopes. A very high power has, however, so many disadvantages, in the difficulty of finding and keeping the object, the contraction of the field, the rapid motion of the image (in reality, the magnified motion of the earth), and the exaggeration of every defect in the telescope, the stand, and the atmosphere, that the student will soon learn to reserve it for special objects and the finest weather, when it will sometimes tell admirably. A very low power is apt to surround bright objects with irradiation, or glare. Experience in all these matters is the surest guide.

It may be very useful to know the diameter of the field of each of our eye-pieces. This may be obtained from the time which an object in or very near the equator takes in passing *centrally* through it; any star having but little declination will answer (γ *Virginis* and δ *Orionis* may be especially mentioned) or the moon or a planet in a corresponding position. Several trials may be made, and the mean result in minutes and seconds of time multiplied by 15 will give the diameter of the field in minutes and seconds of arc, or space, at the equator.

7. Do not be dissatisfied with first impressions. When people have been told that a telescope magnifies 200 or 300 times, they are often disappointed at not seeing the object apparently larger. In viewing Jupiter in opposition with a power of only 100, they will not believe that he appears between two and three times as large as the moon to the naked eye; yet such is demonstrably the case. There may be various causes for this illusion—want of practice—of *sky-room*, so to speak—of a standard of comparison. A similar disappointment is frequently felt in the first impression of very large buildings; St. Peter's at Rome is a well-known instance. If an obstinate doubt remains, it may be dissipated forever when a large planet is near enough to the moon to admit of both being viewed at once - the planet through the telescope, the moon with the naked eye.

8. Do not lose time in looking for objects under unfavorable circumstances. A very brilliant night is often worthless for planets or double stars, from its blurred or tremulous definition; it will serve, however, for grand general views of bright groups or rich fields, or for irresolvable nebulæ, which have no outlines to be deranged; a hazy or foggy night will blot out nebulæ and minute stars, but sometimes defines bright objects admirably; never condemn such a night untried. Twilight and moonlight* are often advantageous, from the diminution of irradiation. Look for nothing near the horizon, unless, indeed, it never rises much above it; nor over, or to the leeward of a chimney *in use*, unless you wish to study the effect of a current of heated air. If you catch a really favorable night, with sharp and steady vision, make the most of it; you will not find too many of them. Smyth, who thinks our climate has been unfairly depreciated, says: "Where a person will look out for opportunities in the mornings as well as evenings, and especially between midnight and daybreak, he will find that nearly half the nights in the year may be observed in, and of these sixty or seventy may be expected to be splendid." But ordinary students must of course take their chance, with their fewer opportunities. With due precaution as to dress, nothing need be feared from "night air;" that prejudice is fully confuted by the well-known longevity of astronomers, even of such as have habitually protracted their watchings

Till the dappled dawn doth rise.

9. In examining faint objects, do not prepare the eye for seeing nothing, by dazzling it immediately beforehand with a lamp, or white paper. Give it a little previous rest in the dark, if you wish it to do its best.†

10. When a very minute star or faint nebula is not to be seen at once, do not give it up without trying *oblique* or *averted vision*, turning the eye towards the edge

*Secchi has found the detail of the Great Nebula in Orion much more visible in moonlight, which is also known not to obliterate even such objects as the satellites of Mars and Uranus, or some of the minuter *comites* of double stars.

†Herschel II, when about to verify his father's observations on the satellites of Uranus, prepared his eye with excellent effect, by keeping it in utter darkness for a quarter of an hour.

of the field, but keeping the attention fixed on the centre, where the object ought to appear; this device, with which astronomers are familiar, is often successful; its principle depends probably on the greater sensitiveness of the sides of the retina.

11. Do not avoid the trouble of recording regularly all you see, under the impression that it is of no use. If it has no other good effect, it tends to form a valuable habit of accuracy; and you might find it of unexpected importance. And, like old Schroter, *trust nothing to memory.* If there has been haste—and sometimes if there has not—it is surprising what unforseen doubts may arise the next day; make at least rough notes at the time, and reduce them speedily into form, before you forget their meaning.

12. Do not be discouraged, by ignorance of drawing, from attempting to represent what you see. Everybody ought to be able to draw; it is the education of the eye, and greatly increases its capacity and correctness; but even a rough sketch may have its use; taken on the spot, and compared with the original, it will not be all untrue; it may secure something worth preserving, and lead to further improvement.

In conclusion, may I be permitted to remind the young observer not to lose sight of the immediate relation between the wonderful and beautiful scenes which will be opened to his gaze, and the great Author of their existence? In looking upon a splendid painting, we naturally refer its excellence to the talent of the artist; in admiring an ingenious piece of mechanism, we cannot think of it as separate from the resources and skill of its designer; still less should we disconnect these magnificent and perfect creations, so far transcending every imaginable work of art, from the remembrance of the Wisdom which devised them, and the Power which called them into being. Such is eminently the right use of the telescope—as an instrument, not of mere amusement or curiosity, but of a more extensive knowledge of the works of the Almighty. So new an aspect as has thus been given to the material universe—so amazing a disclosure as has thus been permitted to man, of the vastness of his Maker's dominion—can hardly be ascribed to blind accident or human contrivance; in thus employing Galileo's invention, we may well feel his grateful acknowledgment, that it was the result of the "previous illumination of the Divine favor,"* to have been not only beautiful but true.

How to Blow Birds' Eggs.

BY ALEXANDER G. GIBBS.

THERE are very few collectors who are not familiar with the old method of blowing birds' eggs, which consisted in making a hole with a pin in each end of the egg, then holding the egg between the thumb and forefinger and blowing steadily through one hole, forcing the contents through the hole in the other end. For the modern, and more scientific way, we must obtain the following instruments:

1. Several egg drills of different sizes.
2. One or two blow-pipes.

These instruments may be obtained from any taxidermist or dealer in naturalists' apparatus.

Having collected our instruments, and secured a specimen, we proceed as follows: Hold the egg between your thumb and finger, or lay it on a table, as may be preferred; place the sharp point of the drill against the shell, then twirl it between your fingers, taking care not to press hard enough to break the egg. After the hole is made, insert the smallest end of the blow-pipe, and blow steadily through the largest end, letting the contents ooze out around the blow-pipe. Of course the hole must be a little larger than the blow-pipe, to allow the contents to escape therefrom.

We have now got our egg blown; the next thing to do is to remove any stains there may be on the shell. First obtain a basin of luke-warm water and a soft rag; dip the egg in the water, and then apply the rag to any stains remaining on the shell, rubbing them carefully until you have succeeded in erasing all of them. The egg is now ready for your collection.

But there are two circumstances which may occur, and for which provision must

*Divina prius illuminante gratia.

be made. 1. The egg may contain an embryo. 2. Suppose the egg may get cracked or broken during the operation of blowing it.

If the former is the case, you must remove the embryo, if possible. There are several ways of doing so, the usual one being to obtain a small pair of scissors with long thin blades, and, inserting them through the hole, cut the embryo to pieces, and hook it out with a crooked pin or some such instrument. There is also another way of which I have read, but I would not advise any collector to attempt it, especially with a rare egg. This is to paste a piece of paper over the hole in the egg, first making a corresponding hole in the paper to fit the one in the egg; then lay the egg on an ant hill and the ants will do the rest—i.e., eat the embryo and leave the shell; but you must be sure and paste the paper on as above described, or the ants will be likely to eat the shell around the hole, and so spoil it for a good collection. If the egg should be cracked, you had better mend it as soon as possible, or you will run the danger of cracking it more. There is a certain cement used for this purpose, but I have never tried it, as I have always mended my cracked or broken eggs in this simple way: Put a thin strip of tissue paper or court plaster (white would be best) and paste it over the whole length of the crack, or enough to prevent it from cracking more.

Filing Saw Teeth.

Most amateurs find great difficulty in keeping their saws in good order. The following directions will be found valuable, although some of them apply only to larger saws than are likely to be used by amateurs. They have been prepared by Mr. J. E. Emerson, member of a well-known firm of saw manufacturers:

The greatest wear of a saw is on the under sides of the teeth. File nearly to an edge (but not quite), leaving a short bevel of say 1-32 of an inch wide on the under side of the point. But in no instance file to a fine point and thin wire edge.

1st. Be sure that the saw hangs properly on the mandrel.

2d. The saw must be in proper line with the carriage, and the carriage run true.

3d. The mandrel must be level and run tight in the boxes.

4th. Round off the saw so that all teeth will cut the same amount, and be sure that the very points of the teeth are widest.

5th. Do nearly all the filing on the upper sides of the teeth, and see that they are well spread at the points; file square, and have them project alike on both sides of the saw.

6th. If the saw heats in the centre when the mandrel runs cool in the boxes, cool it off and line it into the log a little.

7th. If the saw heats on the rim and not in the centre, cool it off and line it out of the log a little.

8th. Do not try the experiment of bending each alternate tooth for the set, when using inserted toothed saws.

9th. File the teeth hooking, so that the swage will spread them at the points.

10th. Use a light hammer in swaging, say three-quarters to one pound weight.

In filing solid toothed circular saws, keep the throats or roots of the teeth round, or as the saws are when new. Angles, or square corners, filed at the roots of the teeth, will almost invariably cause a saw to crack; the filing of such angles or square corners will cancel the warrant on any saw. The back or top of the tooth leads or guides the saw, and should be filed square across. These directions, if carefully followed, will put the saw in excellent condition for cutting, and serve to keep it true in circumference, and even in balance.

Luminous Paint.

The London *Building News* says: "The comparatively recent discovery that luminous paint can be applied as ordinary whitewash, considerably expands the field of its usefulness. Sheets of glass coated with the paint form Aladdin's lamps, which are in use in some of the vessels of the navy, at the Waltham Powder Factory, at Youngs Paraffin Works, and in the spirit vaults of several docks; but now that, by increased production and the use of water as the medium, the cost is reduced by one-half, it will probably be extensively used for painting walls and ceilings. The ordinary form of oil paint has already been applied in many ways to clock-faces, to name-plates and numbers on house-doors, and to notice boards, such as 'mind the step,' 'to let,' etc. The paint emits light without combustion, and therefore does not vitiate the atmosphere. Several experimental carriages are now running on different railways, the paint being used instead of lamps which are necessary all day on account of the line passing through occasional tunnels. It is

reported that a paper at Turin called *Light*, is to appear shortly printed in ink, which will be luminous when darkness sets in. Who can say, indeed, that a policeman when smeared in this luminous composition, will not be sometimes visible on his beat at night?"

Blacking for Leather.

The following has been used for harness, and also for leather bags, boots, etc., and is said to be admirable, if carefully prepared: Ext. logwood, 2 oz.; potass. bichrom, 2 drachms; yellow pruss. potass., 2 drachms; powdered borax, 3 oz.; liq. ammonia, 2 oz.; shellac, 16 oz.; water, 1 gallon. Dissolve the extract in the water, heating the liquid to nearly boiling, then add the chromate and the prussiate of potash. After a deep rich blue color has developed, add the borax, and when it has dissolved add the shellac, and lastly the ammonia; keep the whole at a gentle heat, stirring until the smell of ammonia has gone. The solution of logwood must be heated nearly to the boiling point before the salts of potash are added, or only a dirty blue color will be obtained.

Iridescent Copper.

A new invention for coating iron and steel with iridescent copper, has been devised by Dr. Weil, of Paris, and is thus described in the *Revue Potytechnique*. First, thirty-five parts of crystallized sulphate, or an equivalent amount of any other salt of copper, are precipitated as hydrated oxide by means of caustic soda or some other suitable alkaline base: this oxide of copper is to be added to a solution of 150 parts of Rochelle salts, and dissolved in 1,000 parts of water; to this 60 parts of best caustic soda is to be added, when a clear solution of copper will be formed.

The object to be coppered is to be cleaned with a scratch brush in an alkaline bath containing organic matter, such as solution of malt, etc. It is then attached as a cathode, immersed in the coppering bath, and treated with the usual precautions, when it will become coated with an adherent film of metallic copper.

As the bath gradually loses its copper, oxide of copper, as above prepared, should be added, to maintain it in a condition of activity, but the quantity of copper introduced should not ordinarily exceed that above prescribed as compared with the quantity of tartaric acid the bath may contain. If the quantity of copper notably exceeds this proportion, certain metallic colors are produced on the surface of the object. These effects may be employed for ornamental and artistic purposes.

According to the time of the immersion, the strength of the current, and the proportion of copper to the tartaric acid, the iridescences may be produced of different shades and tints, which may be varied or intermingled by shielding certain parts of the object by an impermeable coating of paraffine or varnish, while the iridescent effect is being produced on the parts left exposed. All colors, from that of brass to bronze, scarlet, blue, and green, may thus be produced at will.

Practical Hints.

Oil on Woodwork.—Carefully-conducted experiments have demonstrated the fact that seasoned wood, well saturated with oil when put together, will not shrink in the dryest weather. Wheels have been known to run many years, even to wearing out the tires. Very many dollars might be saved annually if this practice was adopted. Boiled linseed oil is the best for general use, although it is now known that crude petroleum on even old wheels is of great benefit.

To Repel Mosquitoes.—Mr. Ivers W. Adams writes from Bathurst, N. B., to *Forest and Stream*, that he tried a dozen prescriptions for repelling mosquitoes, flies, and similar pests, and found none of them effective until he came across the following, which are dead sure every time:

"Three oz. sweet oil, 1 oz. carbolic acid. Let it be thoroughly applied upon hands, face, and all exposed parts (carefully avoiding the eyes) once every half hour, when the flies are troublesome, or for the first two or three days, until the skin is filled with it, and after this its application will be necessary only occasionally. Another recipe, equally efficacious, is: Six parts sweet oil, one part creosote, one part pennyroyal. Either of these is agreeable to use, and in no way injurious to the skin. We have both of these in our camp with us, and all flies keep a safe distance."

Paste.—A correspondent of *New Remedies* gives the following recipe for a paste for use in prescription books and labels:

"I dissolve half an ounce of alum in a pint of boiling water; to this I add an equal weight of flour, made smooth in a little cold water, and a few drops of oil of cloves, letting the whole come to a boil. This paste will keep months. I put it in glass, or ordinary ointment jars. This paste is handy, too, for domestic purposes. My children have many toys that come in wooden boxes, but these will break at the corners and soon come to pieces. When a box begins to give out, I take a piece of cambric or calico, and with the brush and paste cover the box so that it will bear constant usage for months. Then, if the cover gives out, I pull it off and put on another one. Again, a doll's arm or leg comes off; but a piece of muslin and a bit of paste restores the article, so that it is as good as it was before."

EXCHANGES.

Only those who are *yearly* subscribers, and whose names are entered on our books have the privilege of inserting exchanges.

Exchanges must be on separate slips of paper or postal cards. If mixed with business letters or cards they cannot be used.

Exchanges must not exceed thirty words.

Buying and selling belong to the advertising department.

We reserve the right to omit the exchange column, when we have not room for it, and the amount of space at our disposal will regulate the number of insertions given to each *exchange*, the preference being always given to those who have not previously used our columns.

To exchange, Hugh Miller,s "Cruise of the Betsey," and "The Old Red Sandstone," cloth bound geological books, for lathe, hammock, or "Gray's Manual of Botany." Gus. C. Spaeth, Mt. Carmel, Ills.

F. F. F., Lock Box 83, St. Johnsbury, Vermont, would like to exchange or correspond with persons interested in mineralogy, Oology, philatology, Indian relics, books, entomology, numis matology, etc.

Wanted, a good printing press and type; state what is wanted in exchange. H. A. Kinney, Hamlin, Brown Co., Kansas.

I have a printing press and outfit (cost $15) to exchange for books, microscope, tent, watch, or offers. Henry E. Jacobs, 59 Harvard Street, Boston, Mass.

I have Vols. 2 and 3 of "Nests and Eggs of American Birds," to exchange for Vol. I of YOUNG SCIENTIST, or offers. N. B. Stone, Lock Box 9, Putnam, Conn.

Wanted, a printing outfit or offers, in exchange for baritone cornet, air gun, and other things, a list of which will be furnished upon application. E. S. Nixon, Jr., Box 345, Chattanooga, Tenn.

To exchange, minerals, ores, shells, papers, magazines, books, coins, stamps, for stamps, coins, minerals, stylographic pen, telephone, etc. A. M. Beveridge, P. O. Box 854, Appleton, Wis.

Will exchange minerals for other minerals; state what specimens you desire. E. A. Refsnyder, Phœnixville, Chester Co., Pa.

Wanted, a good powerful second-hand microscope; forward engraving of instrument, stating price, or what is wanted in exchange. L. D. Snook, Barrington, Yates Co., N. Y.

Wanted, botanical specimens of Western, West C ast, and Southern ferns, in exchange for Northern species; lists exchanged. H. N. Johnson, Coeymans, N. Y.

Wanted, copy of "Snowball's Elementary Natural Philosophy." M. B Tausy, Harrisburg, Pa.

A German microscope, with 3 objectives and 5 eye-pieces, condensing lens, etc., resolving Pleurosigma angulatum, will be exchanged for a first-class spectroscope. Clarence L. Speyers, 50 West 17th St., New York.

A new 2x4 engine, worth $60, for a first-class bicycle; also a watch, revolver, and gas stove, for a 6x9 printing press, type, or offers. Geo. L. Lamson, La Fargeville, N. Y.

To exchange, specimens in botany, oology, etc., for those in other localities; botanical correspondents desired. Arthur Fairbanks, St. Johnsbury, Vt.

Te exchange, for other books on scientific and industrial subjects, "Moore's Universal Assistant," "The Young Mechanic;" both quite new. Fred. Whitehead, Box 55, St. Augustine, Fla.

I have a fine concert harmonica, 20 notes, with case, but little used, that I will exchange for Vol. 3, of the YOUNG SCIENTIST. Charlie O. Wells, Hatfield, Mass.

To exchange, birds' eggs and minerals, for minerals, ores, and curiosities. H. G. Emery, 51 Spencer St., Albany, N. Y.

To exchange, for engine or offers, a pair of Bliss Telephones and 200 feet of copper wire. J. W. Grant, 402 Broad St., Newark, N. J.

To exchange, a 2½ octave chromatic xylophone for microscope, microscopical apparatus, scientific books, or offers. J. E. Moore, Box 81, Newcastle, Ind.

I have McAllister's Naturalists' Microscope, with achromatic triplet objectives, used only 2 months, cost $12.00. I wish to exchange for an inch or 2-3 inch objective. Address, with particulars, F. F. Colwell, Urbana, Champaign Co., O.

To exchange for offers; a small lot of microscopic mounting apparatus. List on application to J. N. B., Box 1468, N. Y.

To exchange, books and YOUNG SCIENTIST, and trinkets, for other books, revolver, or stylographic pen. Frank Bicknell, Humboldt, Iowa.

Ancient petrified grain, Indian pottery, birds eggs, papers, magazines, Confederate money, fossils, minerals, to exchange for arrow-heads, Indian relics, Confederate, Continental, and other paper money. Fred T. Brinkerhoff, Box 347, Neenah, Wis.

Minerals, tricks, copper coins, book on pigeons and rabbits, Wilson School History, for book on experiments, or specimens, minerals, stamps or coins. P. R. Bradley, Box 305, Dunkirk, N. Y.

Wanted, a second-hand screw cutting foot lathe, must be in good condition; state what is wanted in exchange, also size and make of lathe. G. A. Clark, Castalia, Iowa.

To exchange, minerals, shells, fossil shells, birds eggs, etc., for minerals, shells, fossils, stuffed birds, birds eggs, and books. U. S. Grant, Des Moines, Iowa.

Wanted, botanical correspondents for the coming season, also amateur correspondents in chemistry. L, Box 70, East Templeton, Wov. Co., Mass.

Wanted, to exchange a well-equipped job printing outfit, for books or offers. Frank A. Niblack, Rockport, Ind.

Will exchange for Vol. 2 of the YOUNG SCIENTIST, instructive books bound in cloth to the value of $1.50. Chas. H. Williamson, 293 Eckford St., Greenpoint, Brooklyn, N. Y.

I have a new Munsen's battery, large size, which I wish to exchange for a good revolver or offers. Robt. T. Boyle, 351 West 83d St., New York.

Hair of American deer to exchange for diatoms, foraminifera, or other material. W. H. Osborn, Chardon, Ohio.

To exchange, full instruction in short-hand writing, and birds eggs, for birds eggs, postage stamps, or offers. M. F. E., 51 Spencer St., Albany, N. Y.

Wanted, specimens in geology, entomology, oology, etc., for those in other localities, also coins and a charm microscope (magnifies 1,000 times) for one having a different view. J. H. Jones, Frankfort, N. Y.

"History of Our Country," by Lossing, in six parts, price $15, to exchange for printing press or offers. Frank Chandler, Waverley, Mass.

Fine Devonian and Carb. fossils for others, especially cretaceous fossils, scientific books or papers; Pitman's short-hand works for books or offers. A. Stapleton, East Point, Tioga Co., Penn.

Wanted, scientific books and apparatus; send lists and say what is wanted in exchange. Ewing McLean, Greencastle, Ind.

For printing press or offers, achromatic telescope, $8.50; microscope, $5; set drawing instruments, $3; revolver, $3; Phrenological Journal, $2.50; books, 12 plays, farces, dramas, burlesques, etc., $1.80. F. E. Payne, Alma, Mich.

The Young Scientist

SCIENCE IS KNOWLEDGE. KNOWLEDGE IS POWER.

A PRACTICAL JOURNAL OF

HOME ARTS.

VOL. IV. NEW YORK, SEPTEMBER, 1881. No. 10.

How to Learn to Swim.

LET the learner choose for his first lessons a warm day, about noon, or, if he may be strong enough for it, in the morning, shortly after rising, having first partaken of a dry biscuit, or, in the evening, not later than, say eight o'clock. In no case should any one enter water sooner than, at least, seventy-five or eighty minutes after meals. Neither should bathing be indulged in when the body is perspiring profusely. The opposite extreme is as bad; no one can hope to enjoy a bath in cold water, if he has to enter it when the body is chilled. Many accidents occur to practiced swimmers for want of proper attention to the condition of the body and stomach when bathing.

Let the pupil bear in mind that, to be successful, there are three essentials, viz.:

Confidence in the buoyancy of the body when the proper motions are made.

Presence of mind to think on and perform the necessary movements.

Determination to learn.

Do not jump or dive from a height into the water until accustomed to the slight shock experienced by learners. Walk quickly into the water, until immersed to the middle of the body; turn the face to the shallow water, and duck the whole body and head by bending the knees, the one foot being behind the other. Have a friend to support the body by means of a strap, passed round the chest under the armpits, and meeting in the hollow between the shoulders. This can be done best by the teacher leaning over the stern of a small punt. In this position he can see every portion of the pupil's limbs, and can direct the movements very easily, without entering the water at all. Get the body into position by throwing the head well forward, lift the feet off the ground, and stretch the legs as far apart as possible. This position of the nether limbs gives them floating power, and keeps them close to the surface of the

water. To make the lesson simple, there are three motions of legs and arms, which are numbered, and must be accurately performed as follows:

With the arms—Bring the hands with the palms close together, in front of the chest and directly under the chin, the fingers pointing straight in front.

At "one," stretch the arms out to their full extent in front, the palms still close together, and the hands about two inches under the surface of the water.

At "two," separate the hands and turn the wrists slightly until the hands are lying flat on the water; now brace the wrists, and, without bending the elbows, bring the arms slowly round, describing with each a quarter circle, until hands, arms and shoulders are in a straight line across.

At "three," let the palms face toward the feet, and bring the hands in a straight line to the position whence they started. While this movement is being performed, the fingers should be pointed partly to the bottom of the pond and in a slanting direction toward the front.

Practice these movements until they are performed accurately. Now keep the hands in the third position, and practice the kick before beginning, which brings the feet close up to the body, toes and knees turned in the same direction outward.

With the legs—At "one," kick the legs out to their full extent, as wide apart as possible. Be sure, when practicing this part of the kick, to have the toes turned to the side outward, and keep the ankles perfectly stiff.

At "two," brace the knees, toes turned downward, and, without jerking, bring the legs together, joint for joint.

At "three," bring the feet close up to the body, the heels touching and the knees again turned to the side, the toes to be pointed sideways immediately the feet are close to the body.

Practice these movements slowly, distinctly, and separately, until each one is performed perfectly. Then begin the movements of arms and legs simultaneously as follows:

At "one," put the arms out in front, and kick the legs wide apart.

At "two," bring the arms round, describing the quarter circle, at the same time pulling the legs together until they touch.

At "three," return the hands to the original position, and bring the heels close up to the body, knees and toes turned out.

Work, with legs and arms in unison, slowly at first, and counting each movement. In a short time the motions will be performed quite mechanically, and, once they are learned, they are not easily forgotten.

The following hints in reference to the movements will be of some service to the advanced swimmer as well as to the learner:

While performing the first part of the kick, be sure the legs are as wide apart as possible from each other, the effort being made to kick sideways and backward, not downward. The reasons for this are obvious. In the first place, kicking downward gives an ungainly jerk to the body, spoiling the appearance of the stroke, and is also a waste of strength, as it sends the body, or part of it, out of the water, while every effort should be made to propel the body forward.

Number two of the kick is the most important motion of any, and, strange to say, the one most neglected by self-taught swimmers. It is actually the propelling power in swimming; for, when the legs are brought firmly together, the body is shot forward. Therefore, the wider the legs are kicked apart, and the firmer they are pulled together, the greater will be the speed attained. Every swimmer should have this constantly in mind.

The motions one and two of the legs should be performed in as nearly one movement as possible.

The instructions as to the movement of the ankle-joint, in number three, should be also borne in mind, as it is indispensable to perfection in swimming, and is done that there may be as little friction or resistance as possible when the feet are being returned to renew the stroke. The toes are turned out again, to allow of the feet being kicked out with less waste of strength than could otherwise be the case.

Do not hitch the body in any way; the limbs must do all the work. Keep the neck stiff, and make no effort to raise the head above the surface of the water beyond the motion of arms and legs. The weight of the head is diminished considerably when it rests on or in the water. The body and legs should be level, the head being very slightly raised.

Many swimmers experience difficulty in regulating the breathing. There should be no difficulty at all in breathing as regularly in the water as when walking on terra firma, once the first disagreeable feeling in learning it has been got over. The fastest and best of our living swimmers have the mouth and nostrils immersed in the water for at least two-thirds of the time they are swimming. This, along with the improved side and overhand stroke, accounts for the very fast swimming that is being performed, at the matches especially. The mouth and nostrils lie deepest in the water at the beginning of the stroke—that is, when the hands are being stretched in front, while they are raised just above the level of the water as the arms are brought around in the second position. Therefore, to breathe regularly the swimmer should exale or partly empty the lungs at once. This is easily done, although the mouth is under water. The lungs are then filled in an instant, quite easily, during the second part of the stroke. Be sure to breathe regularly every stroke, and never completely empty the lungs. Care must at first be taken not to open the mouth too soon, or water instead of air will be taken in. Presence of mind is essential to the learner. It is also indispensable to the best swimmer. Let the swimmer always bear in mind that, no matter how tired he may be, if not actually cramped, by turning on his back the slightest movement of legs or arms will support him on the surface of the water; or, take a good long breath, expand the chest, keep the head well back, and lie perfectly still; then he will have time to consider what had best be done. In all likelihood he will be sufficiently rested to resume the journey back again, if help has not arrived. One thing all swimmers should guard against: that is, not to allow themselves to go too far out with the current when the tide is ebbing. The best swimmers will find it hard work making headway against some currents. Another error to be guarded against is remaining in the water too long at a time. To practice swimming with a view to benefit by its healthful effects, the stay in the water ought not to be prolonged beyond from eight to ten minutes.

Marvels of Pond Life.

ONE of the most interesting books in the library of the amateur microscopist is the "Marvels of Pond Life," by Mr. Henry J. Slack, late secretary to the Royal Microscopical Society. This book deals entirely with microscopic forms of animal life, and the common experience of all microscopists confirms the assertion made by Dr. Goring, that the most fascinating objects are living creatures of sufficient dimensions to be easily understood with moderate magnification; and in no way can objects of this description be so readily obtained, as by devoting an occasional hour to the examination of the little ponds which are accessible from almost any situation. A complete volume of pond lore would not only be a bulky book, but its composition would overtask all the philosophers of our day. In good truth, a tea-spoonful of water from a prolific locality often contains a variety of living forms, every one of which demands a profound and patient study, if we would know but a few things concerning it.

There is an irresistible charm in the effort to trace *beginnings* in nature. We know that we can never succeed; that each discovery, which conducts back towards some elementary law or principle, only indicates how much still lies behind it: but the geologist nevertheless loves to search out the first or oldest traces of life upon our globe; and so the microscopist delights to view the simplest exhibitions of structures and faculties, which reach their completion in the frame and mind of man. That one great plan runs through the whole universe is now universally accepted truth, and when applied to physi-

ology and natural history, it leads to most important results.

Unfortunately, the book to which we have referred is somewhat scarce and therefore we feel that we are doing our readers a great service by reproducing it in these pages.

PLAIN HINTS ON MICROSCOPES AND THEIR MANAGEMENT.

The microscope is rapidly becoming the companion of every intelligent family that can afford its purchase, and, thanks to the skill of our opticians, instruments which can be made to answer the majority of purposes may be purchased for from $20 to $60, while even those of lower price are by no means to be despised. While the cheap instruments manufactured in quantities by those who do not even care to put their names on them will rarely give satisfaction, it will be found that the average production of respectable houses in England, France, Germany, and America, exhibit so high a degree of excellence as to make comparisons invidious. We shall not, therefore, indulge in the praises of particular firms, but simply recommend any reader entering upon microscopic study to procure an achromatic instrument, if it can be afforded, and having at least two powers, one with a focus of an inch or two-thirds of an inch, and the other of half or a quarter. Cheap microscopes have usually only one eye-piece, those of a better class have two, and the best are furnished with three, or even more.

The magnifying power of a compound microscope depends upon the focal length of the object-glass (or glass nearest the object), upon the length of the tube, and the power of the eye-piece. With regard to object-glasses, those of shortest focal length have the highest powers, and the longest eye-pieces have the lowest powers. The body of a microscope, or principal tube of which it is composed, is, in the best instruments, about nine inches long, and a draw tube, capable of being extended six inches more, is frequently useful. From simple optical principles, the longer the tube the higher the power obtained with the same object-glass; but only object-glasses of very perfect construction will bear the enlargement of their own imperfections, which results from the use of long tubes; and consequently for cheap instruments the opticians often limit the length of the tube, to suit the capacity of the object-glasses they can afford to give for the money. Such microscopes may be good enough for the generality of purposes, but they do not, with glasses of given focal length, afford the same magnifying power as is done by instruments of better construction. The best and most expensive glasses will not only bear long tubes, but also eye-pieces of high power, without any practical diminution of the accuracy of their operation, and this is a great convenience in natural history investigations. To obtain it, however, requires such perfection of workmanship as to be incompatible with cheapness. An experienced operator will not be satisfied without having an object-glass at least as high as a quarter, that will bear a deep eye-piece, but beginners are seldom successful with a higher power than one of half-inch focus, or thereabouts, and before trying this, they should familiarize themselves with the use of one with an inch focus.

It is a popular error to suppose that enormous magnification is always an advantage, and that a microscope is valuable because it makes a flea look as big as a cat or a camel. The writer has often smiled at the exclamations of casual visitors, who have been pleased with his microscopic efforts to entertain them. "Dear me, what a wonderful instrument; it must be immensely powerful;" and so forth. These ejaculations have often followed the use of a low power, and their authors have been astonished at receiving the explanation that the best microscope is that which will show the most with the least magnification, and that accuracy of definition, not mere increase of bulk, is the great thing needful.

Scientific men always compute the apparent enlargement of the object by *one* dimension only. Thus, supposing an object one hundreth of an inch square were magnified so as to appear one inch square, it would, in scientific parlance, be

magnified to "one hundred diameters," or one hundred linear; and the figures 100 preceded by the sign of multiplication (thus, × 100) would be appended to any drawing which might be made from it. It is, however, obvious that the length is magnified as well as the breadth; and hence the magnification of the whole surface, in the instance specified, would be one hundred times one hundred, or ten thousand: and this is the way in which magnification is popularly stated. A few moments' consideration will show that the scientific method is that which most readily affords information. Any one can instantly comprehend the fact of an object being made to look ten times its real length; but if told that it is magnified a hundred times, he does not know what this really means, until he has gone through the process of finding the square root of a hundred, and learnt that a hundredfold magnification means a tenfold magnification of each superficial dimension. If told, for example, that a hair is magnified six hundred diameters, the knowledge is at once conveyed that it looks six hundred times as broad as it is; but a statement that the same hair is magnified three hundred and sixty thousand times, only excites a gasping sensation of wonder, until it is ascertained by calculation that the big figures only mean what the little figures express. In these articles the scientific plan will always be followed.

If expense is not an object, a binocular instrument should be purchased, and it is well to be provided with an object-glass as low as three or even four inches focus, which will allow the whole of objects having the diameter of half an inch or more to be seen at once. Such a low power is exceedingly well adapted for the examination of living insects, or of the exquisite preparations of entire insects, which can now be had of all opticians. Microscopes which have a draw tube can be furnished with an *erector*, an instrument so called because it erects the images, which the microscope has turned upside down, through the crossing of the rays. This is very convenient for making dissections under the instrument; and it also gives us the means of reducing the magnifying power of an object-glass, and thus obtaining a larger field. The erector is affixed to the end of the draw tube, and by pulling it out, or thrusting it in, the rays from the object-glass are intercepted at different distances, and various degrees of power obtained.

A binocular microscope is most useful with low powers from two-thirds upwards. A new form, devised by Mr. Stephenson, acts as an erector, and is very valuable for dissections. It works with high powers.

Beginners will be glad to know how to obtain the magnifying power which different objects require, and it may be stated that, with a full-sized microscope, a two-inch object-glass magnifies about twenty-five diameters with the lowest eye-piece; a one-inch object-glass, or two thirds, from fifty to sixty diameters; a half-inch about one hundred; a quarter-inch about two hundred. The use of deeper eye-pieces adds very considerably to the power, but in proportions which differ with different makers. One instrument used by the writer has three eye-pieces, giving with a two thirds object-glass powers of sixty, one hundred and five, and one hundred and eighty respectively; and with a fifth, two hundred and forty, four hundred and thirty, and seven hundred and twenty, which can be augmented by the use of a draw tube.

It has been well observed that the illumination of objects is quite as important as the glasses that are employed, and the most experienced microscopists have never done learning in this matter. Most microscopes are furnished with two mirrors beneath the stage, one plane and one concave. The first will throw a few parallel rays through any transparent object properly placed, and the latter causes a number of rays to converge producing a more powerful effect. The first is usually used in daylight, when the instrument is near a window (one with a north aspect, out of direct sunlight, being the best); and the second is often useful when the source of illumination is a candle or a lamp. By varying the angle of the mirror the light is thrown through the object more or less obliquely, and its

quantity should never be sufficient to pain the eye. Few objects are seen to the best advantage with a *large* pencil of perfectly direct light, and the beginner should practice till he is able to obtain that arrangement which produces the best effect.

It is advisable that the hole in the stage of the microscope should be large—at least an inch and a half in diameter—so that the entrance of oblique rays is not obstructed, and it is desirable that the mirror, in addition to sliding up and down, should have an arm by which it may be swung to one side. This enables such oblique rays to be employed as to give a dark field, all the light which reaches the eye being *refracted* by the object through which it is sent. The opticians sell special pieces of apparatus for this purpose, but though they are very useful, they do not render it less desirable to have the mirror mounted as described.

Most microscopes are furnished with a revolving diaphragm, with three holes, of different sizes, to diminish the quantity of light that is admitted to the object. This instrument is of some use, and offers a ready means of obtaining a very soft agreeable light for transparent objects, viewed with low powers. For this purpose cut a circular disc of India or tissue paper, rather larger than the biggest aperture; scrape a few little pieces of spermaceti, and place them upon it, then put the whole on a piece of writing paper, and hold it a few inches above the flame of a candle, moving it gently. If this is dexterously done, the spermaceti will be melted without singeing the paper, and when it is cold the disk will be found transparent. Place it over the hole in the diaphragm, send the light through it, and the result will be a very soft agreeable effect, well suited for many purposes, such as viewing sections of wood, insects mounted whole, after being rendered transparent, many small water creatures, etc. Another mode of accomplishing this purpose is to place a similarly prepared disk of paper on the flat side of a bull's-eye lens, and transmit the light of a lamp through it. This plan may be used with higher powers, and the white opaque light it gives may be directed at any angle by means of the mirror beneath the stage.

An ordinary lamp may be made to answer for microscopic use, but one of the small hand lamps, now so common, is singularly convenient. It is high enough for many purposes, and can easily be raised by one or more blocks. A kerosene lamp on a sliding stand is still more handy, and all the better for a hole with a glass stopper, through which it may be filled.

Many people fancy that the eyes are injured by continual use of the microscope, but this is far from being the case if reasonable precautions are taken. The instrument should be inclined at a proper angle, all excess of light avoided, and the object brought into focus before it is steadily looked at. Most people solemnly shut one eye before commencing a microscopic examination; this is a practical and physiological mistake. Nature meant both eyes to be open, and usually resents a prolonged violation of her intentions in this matter. It requires but a little practice to keep both eyes open, and only pay attention to what is seen by that devoted to the microscope. The acquisition of this habit is facilitated, and other advantages gained, by a screen to keep out extraneous light. For this purpose take a piece of thin cardboard about nine inches square, and cut a round hole in it, just big enough to admit the tube of the microscope, about two inches from the bottom, and equidistant from the two sides. Next cut off the two upper corners of the cardboard, and give them a pleasant-looking curve. Then cover the cardboard with black velvet, the commonest, which is not glossy, answers best, and your screen is made. Put the hole over the tube of the microscope, and let the screen rest on the little ledge or rim which forms an ornamental finish to most instruments. A piece of cork may be gummed at the back of the screen, so as to tilt it a little, and diminish its chance of coming into contact with that important organ the nose. This little contrivance adds to the clearness and brilliancy of objects, and is a great accommodation to the eyes.

One more oculistic memorandum, and

we have done with this chapter. Do not stare at portions of objects that are out of focus, and consequently indistinct, as this injures the eyes more than anything. Remember the proverb, "None so deaf as those that won't hear," which naturally suggests for a companion, "None so blind as those that won't see." It is often impossible to get every object in the field in focus at one time;—look only at that which is in focus, and be blind to all the rest. This is a habit easily acquired, and is one for which our *natural* microscopes are exceedingly grateful; and every judicious observer desires to keep on the best terms with his eyes.

(To be continued.)

Three Amateur Workers—and What They Did—XII.

BY FRED. T. HODGSON.

ON the following evening, Mr. Carpenter, Fred, and Ellwood, were very busy finishing up the umbrella-stand.

Fred was sand-papering it all over with very fine sand-paper, and, as the work was not to be stained or painted, he was very careful in rubbing lengthwise of the grain, for his father had cautioned him not to rub across the grain, as that would leave marks and scratches that would show through the varnish.

Mr. Carpenter was engaged putting on, with short screws, a piece of hoop-iron about an inch wide, to the back of the stand. This hoop-iron had six holes in it, one in each end that permitted of a screw being put in each part, and four screws were put in the thin back at regular intervals. The iron was put up within about four inches of the highest point of the back. The duty of the iron was to hold the stand solidly together at the top; the shelf answers the same purpose at the lower end.

The stand, when smoothed down, was given a coat of Wheeler's Patent Wood-Filler, which gave it a very fine appearance. When the "filler" was dry and hard, a coat of good furniture varnish was applied, which, as Ellwood said, "gave the whole thing a finishing touch."

Two or three days after being finished, the stand was taken into the house, and was placed in position in the hall. Jessie made it her special business to inform every visitor that called; "that they had a new umbrella stand," and "that Fred and Ellwood made it all themselves," and, "that it was the nicest umbrella-stand that was ever made." She always seemed to forget that her father directed the movements of her brothers.

Fred and Ellwood wanted some kind of a bracket or shelf in their bedroom, on which their books and some other things might be placed, so Mr. Carpenter designed a plain bracket, same as the one shown at Fig. 48, and it was decided to

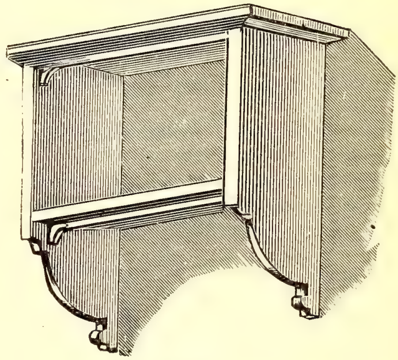

Fig. 48.

make two like it, one for Fred and his brother, and the other for Jessie's sleeping-room.

It was decided to make them of black walnut, so pieces of the following dimensions were obtained for the purpose: Four side-pieces, nine inches wide, seven-eighths thick, and eighteen inches long. Two top shelves, two feet long, ten inches wide, and seven-eighths thick. Two bottom shelves, twenty inches and a quarter long, nine inches wide, and seven-eighths thick. Four bracing pieces, two inches wide, twenty and a quarter inches long, and seven-eighths thick. These lengths and widths were the exact ones, and great care was taken to make the ends as near square as possible, both from their face sides and their edges. Fred smoothed the stuff up with the smoothing-plane very nicely, and his father "laid out" or "marked off" one of the sides same as

shown at Fig. 49, leaving exactly eleven inches space between the underside of the top shelf and the top-side of the bottom one. The shape of the bottom end of the sides is shown at O. When Mr. Carpenter had marked off the shape to suit him, the marked piece was handed over

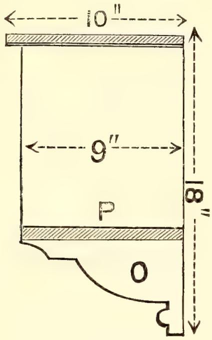

Fig. 49.

to Ellwood to cut out with the scroll saw, with a caution to cut close to the lines and not to feed his saw *too fast*. This caution was quite necessary, as young or inexperienced people apt to "crowd" a saw when they have thick stuff to cut. Ellwood, however, made a good job of the sawing and his father was quite pleased with it.

One of the sides being made to the right shape, and marked over for the bottom shelf, as shown at P, it was laid on the other sides, one by one, and a lead pencil run round the curve and mouldings, which left a line on the uncut pieces, as a guide for the sawyer to make them all alike in shape. The work of sawing the other three sides fell to the lot of Ellwood, who, by the by, had got to be quite an expert

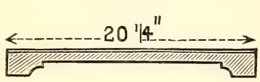

Fig. 50.

in the use of the scroll saw. The next thing Mr. Carpenter did was to mark out one of the bracing pieces to shape, as shown at Fig. 50. When finished, it was handed over to Ellwood to saw, after which operation it was used to mark the other pieces, which were afterwards sawed to shape.

All the stuff was now finished and ready to be put together, so the first thing done was to glue the bracing pieces on to the shelves. On the bottom shelves, they were glued just one inch from the front edge, and being exactly the same length, there was no trouble adjusting the ends. On the upper shelf this matter was a little more difficult to deal with as the shelf was longer and wider than the bottom one, so it was found necessary to keep the bracing piece two inches from the face or front edge, and the ends of it were kept equi-distant from the ends of tne shelf. Mr. Carpenter, after gluing the pieces in place, took a fine brad-awl and made a few holes in the pieces on their under sides, and drove brads in them, taking care that the brads were not too long, as it would have spoiled the work if the points of the nails showed through on the top of the shelves.

The other work was then put together, care being taken that the bottom shelves were glued and bradded on the lines, as shown at P, Fig. 49. A few fine screws were used to fasten the top shelves, but brads only were used in fastening the sides to the lower shelves and to the bracing pieces.

Mr. Carpenter did not put any backs to these brackets because he thought the walls against which they were hung would form all the back required. If the inside back edges had been rabated out about half an inch, and the bottom shelves left half an inch narrower, a back one-half inch thick could have been bradded in the rabats and to the shelves, then the brackets would have been as strong as they were neat and useful.

The work was now, in a measure, completed, with the exception of smoothing and oiling; this part of the work was given over to Ellwood, who sand-papered both brackets with very fine sand-paper, taking care all the time that he never rubbed the paper across the grain, as he was aware that by so doing he would leave scratches and marks that would

be "eyesores" as long as the brackets lasted. When the work was sufficiently smoothed, he applied a light coat of raw linseed oil with a clean linen rag; this darkened the wood and made it look much richer. This operation being over, and the work, so far, being finished to the satisfaction of all concerned, it was necessary to devise some means to attach the brackets to the wall. This was done by procuring two heavy picture-frame rings and fastening them in the brackets through the top shelf, as seen at Fig. 51, where a front elevation of

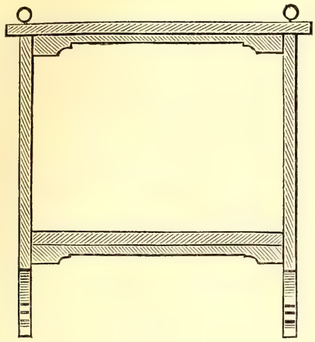

Fig. 51.

the completed work is shown. The rings are on the top in a line with the side pieces.

Picture-frame nails were used to fasten the brackets to the wall, though Mr. Carpenter had some trouble in finding solid places to put them.

The boys left their bracket just as it came from their workshop, but Jessie hung a pair of curtains in front of her's, which gave it a very nice appearance, more particularly as she used the upper shelf for holding a few choice pieces of bric-a-brac, and the lower shelf for books, etc.

"Well, boys," said Mr. Carpenter, after the brackets were hung in their places, "you have done exceedingly well, and if I can judge rightly, I may say that you are now able to do almost any kind of simple amateur woodwork."

Care of Kid Boots.

A writer in the *English Mechanic* says: Sometime ago I found that my tin of harness composition emptied rather too fast. On inquiry, I found that "Mary" had used it for months on "missus'" boots. So I began to investigate and found the boots (two years old) to be in a beautiful condition; I also found that Mary had applied a little regularly, taking care to polish with a soft cloth, and that it was very successful. I make my own blacking. 2 oz. best white wax, ½ oz. prussian blue, 1½ oz. ivory black, ¼ pint spirits turpentine, 1 tablespoonful spirits wine. Melt the wax in earthenware vessel over a slow fire, then add the blue and black, taking care to put in the black by littles at first, or it will boil over; when cool add the spirits. Stir it well from first to last.

Bleaching Ivory for Cutlery Purposes.

Mr. A. H. Mason, in discussing the properties of peroxide of hydrogen before the Liverpool Chemists' Association, said: "It is used in Sheffield to bleach the inferior ivory for knife-handles. The liquid is supplied by an ivory dealer in London, and consists of an aqueous solution of peroxide of hydrogen, of which it contains 2·9 per cent. of rather crude H^2 O^2. The mode of procedure is as follows: Place, say, two quarts of the liquid in a stone pot, adding four ounces liquid ammon. fort. 880°, immerse the handles, and put over a common shop-stove for 24 to 36 hours. The handles are then taken out and gradually dried in the air, not too quickly, or they would split. The deep color of the ivory is removed, and a beautiful pearly white ivory results when polished.

Correspondence.

A Beautiful Wood-Thrush Nest.

Ed. Young Scientist—I was informed by a friend of mine one evening last summer (1880) that he knew where a cuckoo nest was; being anxious to obtain a cuckoo egg, I went next morning to the place designated, but instead of seeing a rude cuckoo nest, I saw a beautiful wood-thrush (*Turdus Mustelinus*) nest which was situated in the fork of a pine tree. It was built inwardly the same as any other wood-thrush nest, but the outside was elaborately draped with long strips of thin paper, some of them measuring a foot or more. As the bird had deserted it, I obtained the nest and two eggs which are at present in my collection.

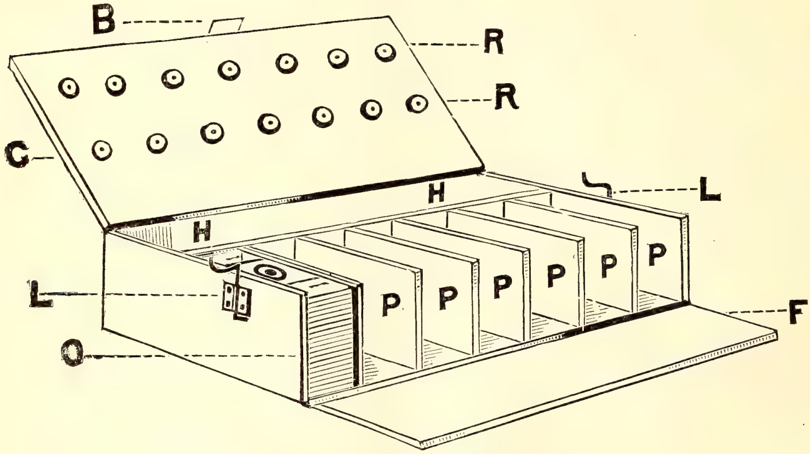
ALEXANDER G. GIBBS.

A Cheap Cabinet for Wooden Slides.

IT is the object of this cabinet to do away with the "elastic band" arrangement, and its inconveniences, and to afford a receptacle for uncovered wooden slides which shall at once exclude all dust from the objects, admit of quick reference, and be cheap and easy of construction.

The slides lie flat as at O, and the objects in each compartment may be indexed by labels pasted on (H H). If the compartments are kept filled with slides (both with and without objects) when the cabinet is shut up, the rubber springs (R R) pressing on the slides will squeeze them together, and so exclude all dust.

A very neat appearance is given to the



A CHEAP CABINET FOR WOODEN SLIDES.

cabinet by covering it with morocco paper.

It consists of a segar box of convenient size, with front (F) and cover (C) hinged. A cloth hinge answers every purpose.

The interior is divided into compartments 3 1-16 × 1 1-6 in. by several partitions, (P P P P P) which are held in place by a piece of wood (H H), fastened in the back of the box and having sawed in it several slots into which the several partitions are glued.

On the cover are attached disks of rubber (R R) (made by cutting small rubber stoppers into four parts) or rubber rings (made from tubing)—the latter being put on upright. There should be two to each compartment; the upper or front ones about ¾ inch from the front edge, and the lower, or back ones, about 1½ in. from them. When the box is closed, the front (F) is kept in place by an overlapping piece of metal, (B) screwed on to the top, and the cover is pressed down by means of two stout wire catches (L L).

FRED. LE ROY SARGENT.

May, 1881.

Back Numbers and Volumes.

WE can supply any back number or volume of the YOUNG SCIENTIST. One number (August, 1880) is now out of print, but, as the pages were electrotyed, we can easily reproduce them and will do so as soon we have taken stock of all the other numbers and know precisely what ones will probably be needed. The prices are: single numbers, six cents; volumes in loose numbers, fifty cents; volumes, neatly bound in cloth, with gilt titles on the back, $1.00 each. At these prices the volumes and numbers will be sent free to those ordering them. Postage stamps of small denomination will be received at full value for sums less than $1.00.

Our New Catalogue of Books.

WE have just issued a new catalogue containing a description of our most recent publications. A copy will be sent free to any one who requests it.

Cheap and Useful.

WE find that we have on hand a few copies of the *first* edition of the "Amateur's Handbook of Practical Information for the Laboratory and the Workshop." It contains quite a large number of useful recipes and directions for mechanical processes. In order to close out the remainder of this edition, we will send a copy to any address, on receipt of seven cents in postage stamps.

BOOK NOTICES.

Celestial Objects for Common Telescopes. By the Rev. T. W. Webb, M.A., F.R.A.S. Fourth Edition, Revised and Greatly Enlarged. New York: The Industrial Publication Company. 1881.

This work is too well known to require a lengthened notice at our hands. It has been out of print for some time, and the eagerness with which stray copies of the third edition have been picked up, shows the value of the book to all amateur astronomers. The edition before us is in reality the *English* edition, merely bearing the imprint of the Industrial Publication Company. It forms a substantial volume of 493 pages, with the well-known Map of the Moon, and very highly executed illustrations of many specially interesting points. No person that takes enough interest in astronomy to point even a common opera-glass at the heavens can afford to be without it.

Lowey's First Steps in Chemistry: A Series of one hundred and fifty select and amusing Chemical Experiments, Free from Danger. Frederick Lowey, Brooklyn, N. Y.

This is a little hand-book designed to accompany the chemical cabinets put up by Mr. Lowey. It describes a great many pleasing experiments which are easily performed. Some of the experiments (98, for example) will hardly succeed when carried out precisely in the manner indicated, but the majority of the directions are reliable. It would have been well, however, if the old methods, which are given in some cases for determining quantities, had been replaced by something more definite and easily understood. A "penny worth" is a very indefinite quantity, and besides that, we have no coin which can be accurately called a "penny." So in the case of "spirits of wine." A country druggist will probably say he has none; he knows it as alcohol of about 90 per cent. And it is useless to tell the reader to use pyro-acetic spirit as a cheap substitute, because it is not usually found in our drug-stores, although a common article in England. But notwithstanding these defects the book will afford a great deal of instructive amusement to those who attempt to follow its directions.

Practical Hints.

Ink for the Hectograph.—Anilin color, 5·0; alcohol, 5·0; mucilage of acacia, 5·0; water, 35·0. Dissolve by means of heat, and strain through flannel or cotton.

Cement for Bisulphide Prisms.—A good cement to fasten the sides of bisulphide of carbon prisms is made of a mixture of good glue and concentrated glycerine, the composition used for making rollers in printing presses.

Labels.—Paper labels, attached in the usual manner, and, when dry, varnished over with two or three coats of good copal varnish, will be found to resist almost all chemicals except liquor potassæ and liquor sodæ.

To Make Tents and Awnings Waterproof. Tents made of very light canvas will become perfectly waterproof, as well as proof against mildew, if first soaked in a strong solution of soap, and afterwards passed through a liquid made by dissolving equal parts of alum and sulphate of copper in five times their united weight of water.

Stains of Tar.—It is said that tar may be instantaneously removed from hand and fingers by rubbing with the outside of fresh orange or lemon peel, and wiping dry immediately. It is astonishing what a small piece will clean. The volatile oils in the skins dissolve the tar, so that it can be wiped off.

Fair of the American Institute.—The semi-centennial fair of the American Institute is held this year in the Rink, on Third Avenue, near Sixty-third Street. These fairs are amongst the most important educational agents we have. They present to the young a continuous series of object lessons of the most instructive kind, and should command the attention of all parents and teachers.

Coppering and Bronzing Zinc.—The following recipes for coppering and bronzing zinc are said to produce quite beautiful results: Prepare a solution of fifteen parts of blue vitriol and one of nineteen parts of cyanide of potassium, then mix both solutions together. Incorporate this liquid well with one hundred and sixty parts of pipe-clay, and rub the semi-fluid mass obtained by means of a linen rag, on the previously cleaned object. For bronzing, take fifteen parts of verdigris, nineteen of cream of tartar, and thirty parts of crystallized soda, reduce them to powder, and dissolve them in the necessary amount of water. Mix this liquid together with

one hundred and sixty parts of pipe-clay, and proceed as above directed. Another process is as follows: Take fifteen grammes of blue vitriol, twenty of calcined soda, mix them well with thirty-two cubic centimetres of glycerine, and mix the paste obtained with eighty grammes of pipe-clay. It is then ready to be applied as before stated.

The Obelisk in the Central Park, New York, weighs two hundred tons, or is equivalent to the weight of about eight hundred and twenty millions of Esterbrook's Ladies' Pens.

EXCHANGES.

Only those who are *yearly* subscribers, and whose names are entered on our books have the privilege of inserting exchanges.

Exchanges must be on separate slips of paper or postal cards. If mixed with business letters or cards they cannot be used.

Exchanges must not exceed thirty words.

Buying and selling belong to the advertising department.

We reserve the right to omit the exchange column, when we have not room for it, and the amount of space at our disposal will regulate the number of insertions given to each *exchange*, the preference being always given to those who have not previously used our columns.

To exchange, Hugh Miller,s "Cruise of the Betsey," and "The Old Red Sandstone," cloth bound geological books, for lathe, hammock, or "Gray's Manual of Botany." Gus. C. Spaeth, Mt. Carmel, Ills.

F. F. F., Lock Box 83, St. Johnsbury, Vermont, would like to exchange or correspond with persons interested in mineralogy, Oology, philatology, Indian relics, books, entomology, numis matology, etc.

Wanted, a good printing press and type; state what is wanted in exchange. H. A. Kinney, Hamlin, Brown Co., Kansas.

I have a printing press and outfit (cost $15) to exchange for books, microscope, tent, watch, or offers. Henry E. Jacobs, 59 Harvard Street, Boston, Mass.

I have Vols. 2 and 3 of "Nests and Eggs of American Birds," to exchange for Vol. I of Young Scientist, or offers. N. B. Stone, Lock Box 9, Putnam, Conn.

Wanted, a printing outfit or offers, in exchange for baritone cornet, air gun, and other things, a list of which will be furnished upon application. E. S. Nixon, Jr., Box 345, Chattanooga, Tenn.

To exchange, minerals, ores, shells, papers, magazines, books, coins, stamps, for stamps, coins, minerals, stylographic pen, telephone, etc. A. M. Beveridge, P. O. Box 854, Appleton, Wis.

Will exchange minerals for other minerals; state what specimens you desire. E. A. Refsnyder, Phœnixville, Chester Co., Pa.

Wanted, a good powerful second-hand microscope; forward engraving of instrument, stating price, or what is wanted in exchange. L. D. Snook, Barrington, Yates Co., N. Y.

Wanted, botanical specimens of Western, West Coast, and Southern ferns, in exchange for Northern species; lists exchanged. H. N. Johnson, Coeymans, N. Y.

Wanted, copy of "Snowball's Elementary Natural Philosophy." M. B Tausy, Harrisburg, Pa.

A new 2x4 engine, worth $60, for a first-class bicycle; also a watch, revolver, and gas stove, for a 6x9 printing press, type, or offers. Geo. L. Lamson, La Fargeville, N. Y.

To exchange, specimens in botany, oology, etc., for those in other localities; botanical correspondents desired. Arthur Fairbanks, St. Johnsbury, Vt.

To exchange, for other books on scientific and industrial subjects, "Moore's Universal Assistant," "The Young Mechanic;" both quite new. Fred. Whitehead, Box 55, St. Augustine, Fla.

A German microscope, with 3 objectives and 5 eye-pieces, condensing lens, etc., resolving Pleurosigma angulatum, will be exchanged for a first-class spectroscope. Clarence L. Speyers, 50 West 17th St., New York.

I have a fine concert harmonica, 20 notes, with case, but little used, that I will exchange for Vol. 3, of the Young Scientist. Charlie O. Wells, Hatfield, Mass.

To exchange, birds' eggs and minerals, for minerals, ores, and curiosities. H. G. Emery, 51 Spencer St., Albany, N. Y.

To exchange, for engine or offers, a pair of Bliss Telephones and 200 feet of copper wire. J. W. Grant, 402 Broad St., Newark, N. J.

To exchange, a 2½ octave chromatic xylophone for microscope, microscopical apparatus, scientific books, or offers. J. E. Moore, Box 81, Newcastle, Ind.

To exchange for offers; a small lot of microscopic mounting apparatus. List on application to J. N. B,, Box 1468, N. Y.

To exchange, books and Young Scientist, and trinkets, for other books, revolver, or stylographic pen. Frank Bicknell, Humboldt, Iowa.

Ancient petrified grain, Indian pottery, birds eggs, papers, magazines, Confederate money, fossils, minerals, to exchange for arrow-heads, Indian relics, Confederate, Continental, and other paper money. Fred T. Brinkerhoff, Box 347, Neenah, Wis.

Minerals, tricks, copper coins, book on pigeons and rabbits, Wilson School History, for book on experiments, or specimens, minerals, stamps or coins. P. R. Bradley, Box 305, Dunkirk, N. Y.

Wanted, a second-hand screw cutting foot lathe, must be in good condition; state what is wanted in exchange, also size and make of lathe. G. A. Clark, Castalia, Iowa.

To exchange, minerals, shells, fossil shells, birds eggs, etc., for minerals, shells, fossils, stuffed birds, birds eggs, and books. U. S. Grant, Des Moines, Iowa.

Wanted, botanical correspondents for the coming season, also amateur correspondents in chemistry. L, Box 70, East Templeton, Wov. Co., Mass.

Wanted, to exchange a well-equipped job printing outfit, for books or offers. Frank A. Niblack, Rockport, Ind.

Will exchange for Vol. 2 of the Young Scientist, instructive books bound in cloth to the value of $1.50. Chas. H. Williamson, 293 Eckford St., Greenpoint, Brooklyn, N. Y.

I have a new Munsen's battery, large size, which I wish to exchange for a good revolver or offers. Robt. T. Boyle, 351 West 83d St., New York.

Hair of American deer to exchange for diatoms, foraminifera, or other material. W. H. Osborn, Chardon, Ohio.

To exchange, full instruction in short-hand writing, and birds eggs, for birds eggs, postage stamps, or offers. M. F. E., 51 Spencer St., Albany, N. Y.

Wanted, specimens in geology, entomology, oology, etc., for those in other localities, also coins and a charm microscope (magnifies 1,000 times) for one having a different view. J. H. Jones, Frankfort, N. Y.

"History of Our Country," by Lossing, in six parts, price $15, to exchange for printing press or offers. Frank Chandler, Waverley, Mass.

THE Young · Scientist.

SCIENCE IS KNOWLEDGE.

KNOWLEDGE IS POWER.

INDUSTRIAL PUBLICATI

A PRACTICAL JOURNAL OF

HOME ARTS.

VOL. IV. NEW YORK, OCTOBER, 1881. No. 10.

Sizes of Books.

OUR young readers have doubtless been often puzzled to know what was meant by the terms 12 mo., 8 vo., etc., used in describing the sizes of books, and as we have frequently been asked to explain these terms, we will try and make the subject plain.

When a publisher undertakes to put the intellectual labors of an author into the form of a book, one of the first things to be decided is the size of the page, and this generally depends upon the amount of reading matter in the work, though sometimes it is governed by the size of the illustrations or engravings, if there are any. At first sight this would look as if the book were made for the engravings, and not the engravings for the book; but if the reader will think again he will see that in order to show clearly what is intended to be illustrated, the engravings must have a certain size. If too small, some of the important parts would be visible only by the use of a magnifier.

The price at which the book is to be sold has also an important influence on the size. If the book is to be a handsome holiday volume, the size of the page will probably be larger than if the work is intended for ordinary buyers. This is particularly the case in regard to scientific and industrial books, where great economy is often desirable.

Having decided upon the size that the page ought to be, the next questions are as to the size of paper and the number of times it shall be folded to give the desired page. At first all paper was of the same size, and a sheet when folded once gave four pages, which were of the size known as *folio*. Folded again, there were eight pages, and the size was called *quarto*. But eight pages make four leaves; hence *quarto* (or 4to.) expresses the number of *leaves* to the sheet, and not the number of pages. Folded again, the sheet gives us eight leaves or sixteen pages, and is called an octavo, which, when written, is

often contracted to 8vo, or 8°, and is sometimes, though barbarously, pronounced eight-vo. Hence we see that by simply folding over and over again we get the following series. A sheet folded

Once	gives	two	leaves	called	Folio.
Twice	"	four	"	"	Quarto.
Thrice	"	eight	"	"	Octavo.
Four times	"	sixteen	"	"	Sexto-decimo.
Five times	"	thirty-two	"	"	Trigesimo-secundo.

If our readers will take a sheet of any kind of paper, and cut it to the size of 24 by 19 inches, and will fold it over and over again, they will get a clearer idea of this matter than by any amount of description. They will also find that when folded three times the page will be the same size as that of the YOUNG SCIENTIST, and they will therefore conclude, and rightly, that the latter is an octavo.

An ordinary sheet of paper may, however, be folded otherwise than by a constant process of *halving*, for that is what the system of folding that we have just described amounts to. Thus, instead of halving the sheet, we may fold it twice so as to divide it into *three* parts instead of two, as when we folded it once. When these are folded on each other they form a long three-ply strip, and when this strip is folded twice, so as to divide it into four parts we have twelve leaves or twenty-four pages, and this is called a *duodecimo* (generally written 12mo.) In a similar way the sheet may be folded into eighteen and other numbers of leaves, it being always understood that the number refers to the *leaves* and not the pages. This is the point at which most people are apt to get befogged; there are three things which the terms might express, viz.: the number of *folds*, the number of *leaves*, or the number of *pages*. It is the number of of leaves that is meant.

But since paper is found in sheets of different sizes, the preceding system tells us merely the number of leaves to the sheet, and gives no definite clue to the size of the work. Hence we actually find some 12mo. books which are as large as some 8vo. ones. As a further guide to size, therefore, we have the size of the paper sometimes given, and we find such expressions as Royal Octavo, Demy Octavo, Crown Octavo, etc. But even in the most elaborate form this system does not meet the requirements of the case, and various schemes have been devised for the purpose of giving exactness to the terms used. One of the worst is that fixed upon by the Associated Librarians of Great Britain, who have ignored everything but the foot rule, and have adopted the following scale of measurements, the inferior limit of each size being the superior limit of the size below it:

NAME.	CONTRACTED TO.		SIZE	
Large folio	la. f°	over	18	inches
Folio	f°	below	18	"
Small folio	sm. f°	"	13	"
Large octavo	la. 8°	"	11	"
Octavo	8°	"	9	"
Small octavo	sm. 8°	"	8	"
Duodecimo	12°	"	8	"
Decimo-octavo	18°	is	6	"
Minimo	m°	below	6	"
Large quarto	la. 4°	"	15	"
Quarto	4°	"	11	"
Small quarto	sm. 4°	"	8	"

To designate unusual sizes the additional terms *square* (sq.), *narrow* (na.), and *oblong* (ob.) are to be used. That it will be difficult to devise a perfect system we fully acknowledge, but any system, to prove acceptable, must do more than tell us the number of inches to which the binder's apprentice has cut down the volume. The size of the printed page and of the type are of quite as much importance to readers and buyers as the mere width of the shelving, which must be used to hold the book.

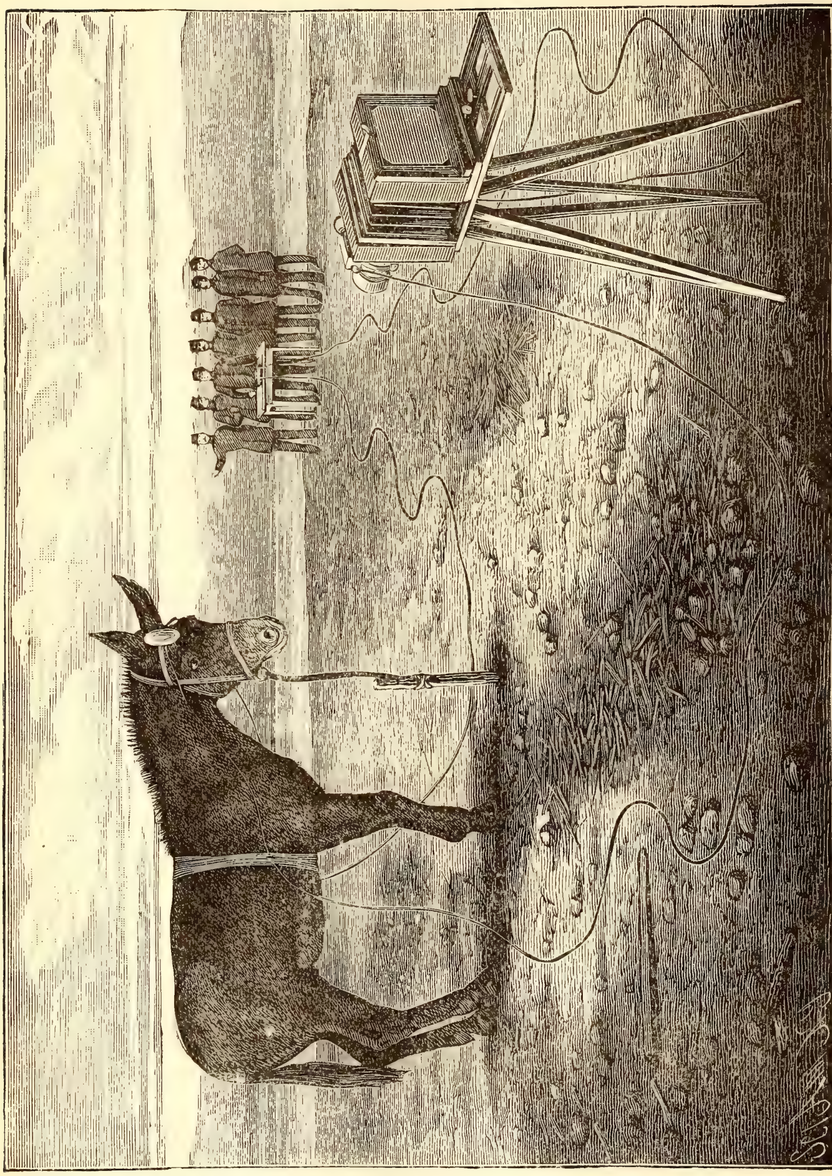
—In many cases mineral oils are not to be recommended as lubricants, since they attack any India rubber with which they may happen to come in contact.

Burnished Gilding on Glass.

IN the first place, it is necessary to make a size for fixing the gold leaf to the glass, which is made in the following manner: Obtain some best isinglass, and place as much in a teacup as will cover a shilling piece; then pour half a cupful of boiling water upon it; then add as much spirits of wine as water in the cup, strain the whole through a piece of fine cambric or a silk handnerchief; when cold it is ready for use. Whatever writing or ornament you require to put on the glass must be first drawn or set on paper the exact size of the glass. When you have made your design or letters on the paper (with a lead pencil) the size you require, prick the outlines through with a fine needle, placing the paper on a piece of smooth, soft wood, so that it does not blunt the point of the needle (and make the holes unnecessarily large). When this is done, clean your glass thoroughly; then place your design, reversed, to back of the side you mean gilding, fixing it with a little gum at each corner; then place your glass in a slanting position. Take a large size swan-quill pencil, and flow the size on where you require the writing or ornaments: then commence gilding, putting your gold out on a cushion, and cutting it the proper sizes, or of such sizes as you can easily take up with the tip. Let each joint overlap the other, gilding the whole space where the writing, etc., is to be, having the gold about one-fourth inch wider at the top and bottom of the letters. When you have completed the gilding so far, the glass should be set upright to drain the surplus size off, and near a fire, or in a warm place, to dry. When dry, which you will ascertain by its assuming a burnished appearance, take a piece of cotton wool and rub it over very softly. By this means you will remove all the loose pieces of gold, and increase the burnish of the gold. If there are any faulty places in the gilding, flow a little size on the place, and put a piece of gold over it, rubbing the place so repaired gently with cotton wool, when dry. Then use a large flat camel-hair brush, and size the whole of the gold over lightly, so as not to disturb the gold. When this is dry, pour some hot water over the gilding, which enhances the brilliancy of the gold very considerably. When dry, which it will do in a very few minutes, size it over softly to prevent the paint from percolating the gold. Having completed your gilding, you take your design off the back of the glass (which enabled you to see how far to gild), and place it on the gilded side, reversed, taking care to fix it securely, so that it shall not move, while you pounce it over with a white pounce softly; then raise the paper off the glass carefully, so as not to brush the pounce marks away. You will then have the outlines of your design left on the gold. Take a sable writing pencil, and fill up the outlines with Brunswick black of as thick consistency as you can work it with the pencil; when this process is quite hard, take a wet sponge, and gently wash all surplus gold off clean. Then take a small straight-edge and a chisel, and cut the top and bottom of the letters, etc., quite straight and true. This process is called trimming, by which means you obtain a sharpness of outline that you could not obtain with the pencil, however expert you may be. You may then shade in what color you think proper, and paint whatever color background over all to suit your fancy.—*Design and Work.*

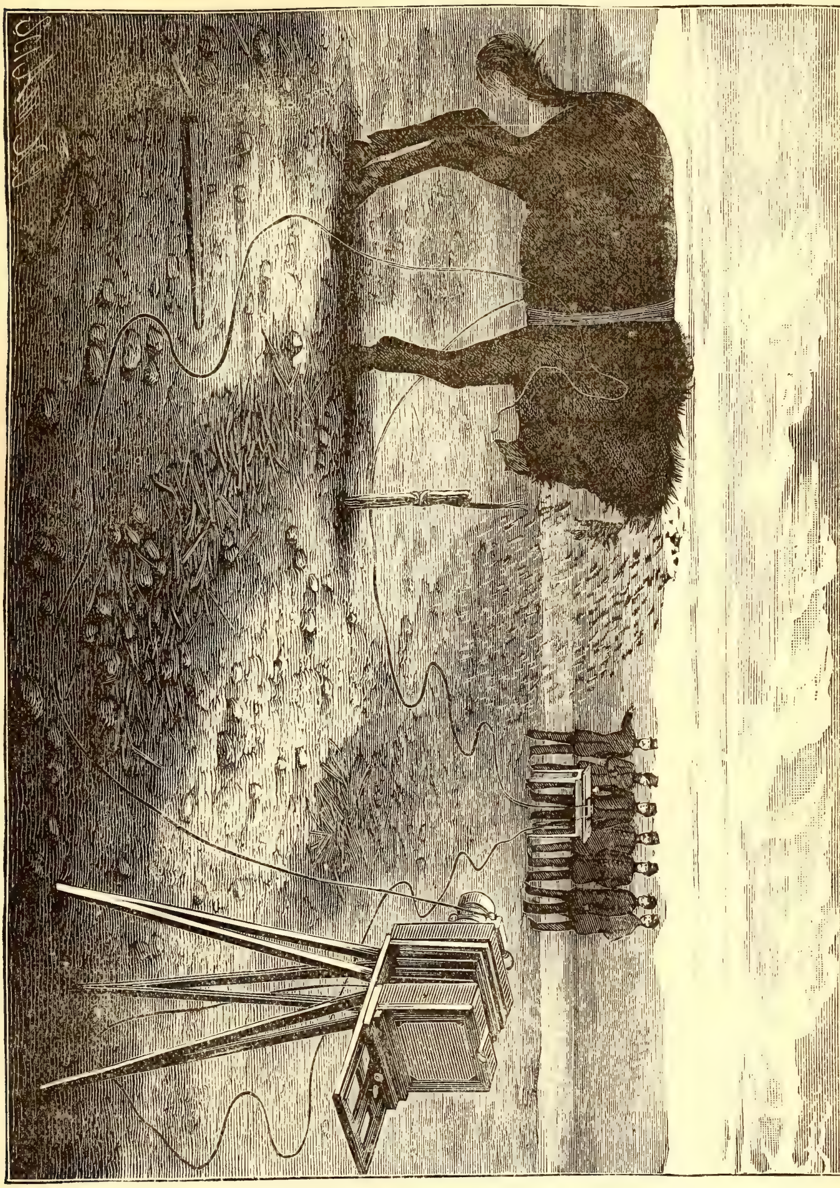
Instantaneous Photography.

WHEN objects are in rapid motion it is very difficult to observe them distinctly. This does not arise from the fact that the eye fails to get an impression of the object, because it can be proved that objects may be distinctly seen even when presented to the eye for less than the one-thousandth part of a second. But owing to what is known as *the persistence of vision*, objects in motion give rise to a series of images on the retina, and as these images overlap, as it were, the result is a confused blur. The best illustration of this is seen in a common experiment well known to every boy and girl. Take a stick with the end on fire and glowing, and move it slowly either back



INSTANTANEOUS PHOTOGRAPHY.

Fig. 1.—BEFORE THE EXPLOSION.



INSTANTANEOUS PHOTOGRAPHY.

Fig. 2.—AFTER THE EXPLOSION.

and forward in a straight line, or whirl it round in a circle. If the motion be sufficiently slow the fiery point will be visible at every portion of its path, but if it completes the circle or returns along the straight line in less than the eighth part of a second, it will appear as a line of light in the one case, and a circle in the other. The cause of this is that the eye again obtains a view of the burning point at the commencement of the line or circle before the image produced by its first appearance there has faded away. It is this fact which renders it so difficult to obtain a clear view of objects in motion. Take the case of trotting horses, for example. Hitherto it has been impossible to analyze their motions, and the most extraordinary theories have been propounded in regard to the matter. Fortunately, however, photography has come to our aid, and a few years since, in San Francisco, Watron took a series of photographs which were so instantaneous that the positions of the limbs at different points of the step were quite clear and distinct. This was due to the fact that the plates used required such a short time for exposure that the limbs did not move through an appreciable space during the interval. More recently, M. Maybridge, of Paris, has taken photographs so rapidly that he has made six pictures during a clown's leap, each picture showing the acrobat in a different position. The time required to take one of these photographs has been proved by M. Marbridge to be less than the 1-100th part of a second.

One of the most remarkable photographs that has come under our observation is that taken under the direction of Gen. Henry L. Abbott, U.S.A., in charge of the Engineer School of Application, Willet's Point, N. Y. It became necessary, one day, at Willet's Point to destroy a worthless mule, and on the 6th of last June the subject was made the occasion of giving useful instruction to the military class there stationed. The mule was placed in proper position before a photo camera and duly focussed. Upon the animal's forehead a cotton bag was tied containing six ounces of dynamite. The slide of the camera was supported by a fuse; the camera fuse and the dynamite on the mule's head being connected in the same electrical circuit, as shown by the wires in our engraving. On pressing the key so as to send the electricity through the wires, both the fuse and the dynamite were simultaneously fired; the camera slide and the head of the animal fell nearly together. The photo sensitive plate was impressed with a picture of the headless creature, still standing, before its body had time to fall.

Fig. 1 of our illustrations, for which we are indebted to the courtesy of the *Scientific American*, shows the animal, camera and electrical wires in position for firing. Fig. 2 shows the appearance of the animal after the explosion, as taken on the photo plate. Here it will be observed that the head has been shattered and blown to one side, hanging by the merest shred of skin. The shock has, however, been transmitted to the entire muscular system of the animal, as will be seen by the appearance of the tail and the hind limbs. One of the most singular circumstances, however, is the fact that the fragment of the halter, by which the mule was fastened to the stake, has not had time to fall, but remains standing as if it were a stiff rod.

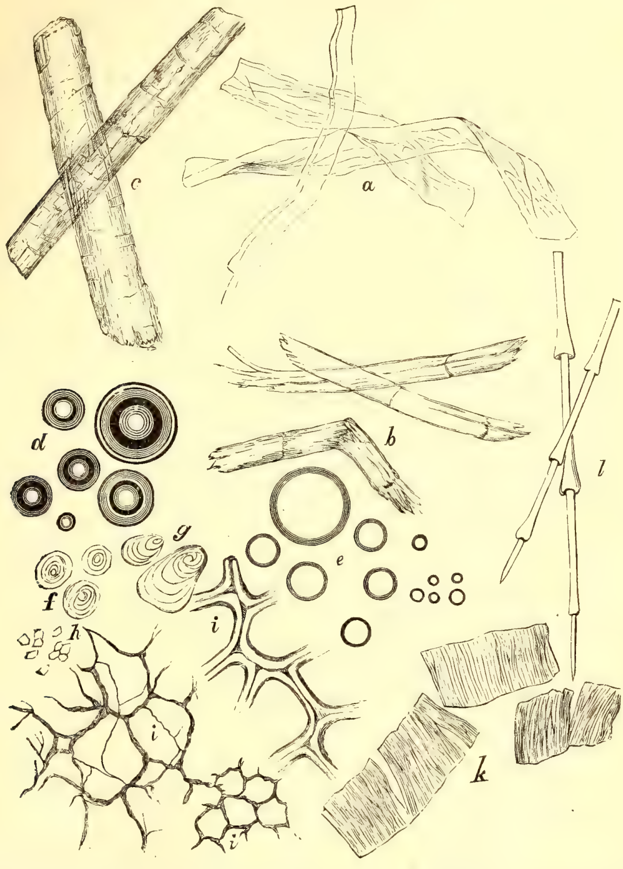
Rubber-Headed Tacks.

A New England firm have patented and are manufacturing a rubber-headed tack whose uses are multifarious. As an insulator for sewing machines they are largely used by the leading manufacturers, and are easily and quickly applied. For household uses they are placed in the backs of chairs to prevent damage to walls; in the ends and sides of door steps; in rabbets of large folding doors; on lids of pianos; in rabbets of rattling window frames, and, in fact, anywhere to overcome the nuisance of rattling. Car manufacturers use them to deaden noise and avoid abrasion of polished surfaces. Carriage manufacturers apply them to stop the rattling of window frames and doors, and for glass frames to drop upon on the inside of doors. Book manufacturers place them on the corners of large books to protect the binding. In schools, slate frames and rattling desk lids demand them. On billiard cues they are used, and obviate the use of chalk. Indeed, there is hardly any limit to which this useful article may not be applied.

Microscopical Mistakes.

ONE of the most common causes of mistakes on the part of young microscopists is the presence of foreign substances in the objects under examination. It is true that these things cause trouble chiefly to beginners with the microscope, but sometimes even experienced hands are led astray. Beale, in his book, "How to Work with the Microscope," relates some curious and astonishing instances of this.

There are certain things which are so universally present that they are liable to make their appearance in spite of the greatest care. Chief amongst these are air bubbles, which present themselves as great round, black objects, which are sure to attract the attention of the young microscopist to the exclusion of everything else. Older observers pay no attention to them. Then the lint from the cloths with which the slides are wiped; particles of dust from the air; fragments of wool from carpets and clothes; dust and splinters from cork and wood; bits of hair, feathers, leaves, etc., etc., are all liable to light on our work. In the accompanying engraving we give the appearence of a few of these things, and



FOREIGN SUBSTANCES LIABLE TO BE FOUND IN MICROSCOPIC PREPARATIONS.

a. Cotton fibres. *b.* Flax fibres. *c.* Hairs. *d.* Air bubbles. *e.* Oil globules. *f.* Wheat starch. *g.* Potato starch, *h.* Rice starch granules. *i, i, i.* Vegetable tissue. *k.* Muscular fibres. *l.* Feathers.

would advize our readers to study them closely, so as to familiarize themselves with the way they look. A better plan, however, is to take the actual objects themselves, and examine them carefully under the microscope. Bubbles, in particular, deserve very careful study. Procure a little gum water and a few phials. In one shake the pure gum water up with air, place a little on a slide, and study the air bubbles. In another put some gum water and a little oil colored with alkanet root; shake them up, put a little on a slide, and study the globules of oil in water. Fill a third half full of oil, add a little gum water, shake the two together, and study the globules of water in oil. A course of study of this kind will prove of inestimable value.

Something New in Entomology.

LAST Sunday, as Mr. Jones was returning from church with his family, he discovered a new and singular-looking bug on his front door-step. As he was something of a scientist, he was pleased with the new specimen, and, forming his pocket-handkerchief into a sort of cage, he pounced down on it and succeeded in capturing it.

"Bring the microscope, children," he called, "and tell your ma to hurry; I want her to look at it; I'm sure it belongs to the Hemiptera class, and is a new specimen. Here, Charlie, put your eye to the ocular side and tell me what you see."

"Oh, pa, ain't it splendid? It's got four wings, eight eyes, and, oh, my! ain't it a-sparkling though? Red and green and yellow, and—oh, it's getting away, ain't it pa?"

"Then it isn't dead!" cried Mr. Jones, in ecstacy; "I wasn't quite sure whether it moved or not. Let me look! Yes, it's a terrestrial, I think, after all; it belongs to the genus Pentoma—the antennæ have that peculiar flexible look; and yet, now that I look again, the eyes seem to indicate that it is a phytocoris, in which case it will be very destructive to your ma's plants, and we must kill it at once. I'll ask Professor Sill. It will be in any case, a valuable addition to science. Maria, where's the chloroform?"

"Up on the clock shelf; what are you going to do with it?" asked Mrs. Jones, who had been giving her undivided attention to the baby.

"Kill this bug as soon as you have examined it," answered Mr. Jones, in a lofty voice. "I shall present it to the scientific association—"

"Well, I guess not, Mr Jones," broke in his wife, who was looking with much interest at the new specimen. "I paid $2 for that bug last week to wear on my new bonnet, and I must have dropped it off when I came in. It belongs to the genus millineræ, and couldn't be any deader if it had been baked for a century. Science will have to get along without it, Jones; it's already classified." Poor Jones.—*Ex.*

Marvels of Pond Life—II.

THE winter months are on the whole less favorable to the collection of microscopic objects from ponds and streams than the warmer portions of the year; but the difference is rather in abundance than in variety, and with a very moderate amount of trouble, representatives of the principal classes can always be obtained.

On a clear January morning, when the air was keen, but no ice had yet skinned over the surface of the water, a visit to some small ponds in an open field not far from Kentish Town provided entertainment for several days. The ponds were selected from their open airy situation, the general clearness of their water, and the abundance of vegetation with which they were adorned. Near the margin confervæ abounded, their tangled masses of hair-like filaments often matted together, almost with the closeness of a felted texture. At intervals, minute bubbles of air, with occasionally a few of greater size, indicated that the complex processes of vegetable life were actively going on, that the tiny plants were decomposing carbonic acid, dexterously combining the carbon—which we are most familiar with in the black opaque form of

charcoal—to form the substance of their delicate translucent tissues, and sending forth the oxygen as their contribution to the purification of the adjacent water, and the renovation of our atmospheric air. This was a good sign, for healthy vegetation is favorable to many of the most interesting forms of infusorial life. Accordingly the end of a walking-stick was inserted among the green threads, and a skein of them drawn up, dank, dripping, and clinging together in a pasty-looking mass. To hold up a morsel of this mass, and tell some one not in the secrets of pond-lore that its dripping threads were objects of beauty, surpassing human productions, in brilliant color and elegant form, would provoke laughter, and suggest the notion that you were poking fun at them, when you poked out your stick with the slimy treasure at its end. But let us put the green stuff into a bottle, with some water from its native haunt, cork it up tight, and carry it away for quiet examination under the microscope at home.

Here we are with the apparatus ready. We have transferred a few threads of the conferva from the bottle to the *live box*, spreading out the fine fibres with a needle, and adding a drop of water. The cover is then gently pressed down, and the whole placed on the stage of the microscope, to be examined with a power of about sixty. A light is thrown somewhat obliquely by the mirror through the object, the focus adjusted, and a beautiful sight rewards the pains. Our mass of conferva turns out to contain one of the most elegant species. Fine hair-like tubes of an organic material, as transparent as glass, are divided by partitions of the same substance into cylindrical cells, through which a slender ribbon of emerald green, spangled at intervals with small round expansions, is spirally wound. We shall call it the Spiral Conferva, its scientific name being *Spirogyra quinina*. Some other species, though less elegantly adorned, make a pleasing variety in the microscopic scene; and appended to some of the threads is a group of small crystal bells, which jerk up and down upon spirally twisted stalks. These are the "Bell Flower Animalcules" of old observers, the *Vorticellæ*, or little Vortex-makers of the present day. Other small creatures flit about about with lively motions, and among them we observe a number of green spindles that continually change their shape, while an odd-looking thing crawls about, after the manner of certain caterpillars, by bringing his head and tail together, shoving himself on a step, and then repeating the process, and making another move. He has a kind of snout, behind which are two little red eyes, and something like a pig-tail sticks out behind. This is the Common Wheel-bearer, *Rotifer vulgaris*, a favorite object with microscopists, old and young, and capable, as we shall see, of doing something more interesting than taking the crawl we have described.

A higher power, say one or two hundred, may be conveniently applied to bring out the details of the inhabitants of our live box more completely; but if the glasses are good, a linear magnification of sixty will show a great deal, with the advantage of a large field, and less trouble in follow- the moving objects of our search.

Having commenced our microscopic proceedings by obtaining some Euglenæ, Vorticellæ, and a Rotifer, we are in a position to consider the chief characteristics of three great divisions of infusoria, which will often engage our attention.

It is well known that animalcules and other small forms of being may be found in *infusions* of hay or other vegetable matter, and hence all such and similar objects were called *Infusoria* by early observers. Many groups have been separated from the general mass comprehended under this term, and it is now used in various senses. The authors of the "Micrographic Dictionary" employ it to designate "a class of microscopic *animals* not furnished with either vessels or nerves, but exhibiting internal spherical cavities, motion effected by means of cilia, or variable processes formed of the substance of the body, true legs being absent." The objection to this definition is, that it to some extent represents theories which may not be true. That nerves are absent *all through the class* is an assumption founded merely upon the negative

evidence of their not having been discovered, and the complete absence of "vessels" cannot be affirmed.

In the last edition of "Pritchard's Infusoria," to which some of our ablest naturalists have contributed, after separating two groups, the Desmids and the Diatoms, as belonging to the vegetable world, the remainder of the original family of infusoria are classified as *Phytozoa, Protozoa, Rotifera,* and *Tardigrada.* We shall explain these hard names immediately, first remarking that the Desmids and the Diatoms, concerning whom we do not intend to speak in these pages, are the names of two groups, one distinctly vegetable, while the other, although now generally considered so, were formerly held by many authorities to be in reality animal. The Desmids occur very commonly in fresh water. We have some among our Confervæ. They are most brilliant green, and often take forms of a more angular and crystalline character than are exhibited by higher plants. The Diatoms are still more common, and we see before us in our water-drop some of their simplest representatives in the form of minute boats made of silica (flint) and moved by means still in dispute.

Leaving out the Desmids and Diatoms, we have said that in Pritchard's arrangement the views of those writers are adopted who divide the rest of the infusoria into four groups, distinguished with foreign long-tailed names, which we will translate and expound. First come the *Phytozoa,* under which we recognize our old acquaintance *Zoophyte* turned upside down. *Zoophytes* mean animal-plants, *Phytozoa* mean plant-animals. We shall have by-and-bye to speak of some of the members of this artificial and unsatisfactory group, and postpone to that time a learned disquisition on the difference between animals and plants, a difference observable enough if we compare a hippopotamus with a cabbage, but which "grows small by degrees, and beautifully less," as we contemplate lower forms.

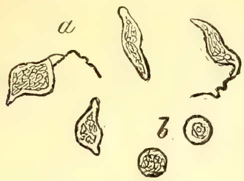
After the *Phytozoa* come the *Protozoa,* or first forms in which animality is distinctly recognized. Under this term are assembled creatures of very various organization, from the extreme simplicity of the *Proteus* or *Amœba,* a little lump of jelly, that moves by thrusting out portions of its body, so as to make a sort of extempore legs, and in which no organs can be discerned,* up to others that are highly developed, like our *Vorticellæ.* This group is evidently provisional, and jumbles together objects that may be widely separated when their true structure and real affinities are discerned.

Following the *Protozoa* come the *Rotifera,* or Wheel-bearers, of which we have obtained an example from our pond, and whose characteristics we shall endeavor to delineate when our specimen is under view; and last in the list we have the *Tardigrada,* "Slow-steppers," or Water Bears, queer little creatures, something like new-born puppies, with a double allowance of imperfect feet. These, though somewhat conected with the rotifers, are considered to belong to a low division of the arachnida (spiders, etc.)

Feeling that we must be merciful with the long-tailed words and explanations of classification, we reserve further matter of this kind for the opportunities that must arise, and direct our attention to living forms by watching the *Euglenæ* which our water-drop contains. We have before us a number of elegant spindle-shaped bodies, somewhat thicker in front than behind, and in what may be called the head there glitters a brilliant red speck, commonly called an *eye-spot,* although, like the eyes of potatoes, it cannot see. Round this eye-spot the tissues are clear, like glass; but the body of the creature is of a rich vegetable green, which shines and glistens as it catches the light. Some swim rapidly with a rollicking motion, while others twist themselves into all manner of shapes. Now the once delicate spindle is oddly contorted, now it swells out in the middle, like a top, and now it rolls itself into a ball. The drawings will afford some idea of these protean changes, but they must be seen before their harlequin character can be thoroughly appreciated. Some of the specimens exhibit delicate lines running lengthwise,

*In some kinds and in some stages of growth this is not strictly true.

and taking a spiral twist as the creature moves about; but in none can any mouth be discerned, and their antics, although energetic and comical, afford no certain



a, motile; and *b*, resting condition of Euglenæ.

indications of either purpose or will. What are they? animals or vegetables? or something betwixt and between?

The first impression of any casual observer would be to declare in favor of their animality; but before this can be settled comes the question, what is an animal, and how does it differ from a vegetable? and upon this the learned do by no means agree. One writer considers the presence of *starch* in any object a proof that it belongs to the dominions of Flora, while another would decide the issue by ascertaining whether it evolves oxygen and absorbs carbon, as most plants do, or whether it evolves carbon and absorbs oxygen, as *decided* animals do. Dr. Carpenter asserts that the distinction between *Protophyta* and *Protozoa* (first or simplest plants and animals), "lies in the nature of their food, and the method of its introduction, for whilst the *Protophyte* obtains the materials of its nutrition from the air and moisture that surround it, and possesses the power of detaching oxygen, hydrogen, carbon and nitrogen from their previous binary combinations, and of uniting them into ternary and quaternary organic compounds (chlorophyll, starch, albumen, etc.), the simplest *Protozoa*, in common with the highest members of the animal kingdom, seems utterly destitute of any such power, makes, so to speak, a stomach for itself in the substance of its body, into which it injects the solid particles that constitute its food, and within which it subjects them to a regular process of digestion."

Unfortunately it is very difficult to apply this simple theory to the dubious objects which lie on the borderland of the animal world, and no other theory that has been propounded appears to meet all cases. Some naturalists do not expect to find a broad line of demarkation between the two great divisions of living things, but others characterize such an idea as "unphilosophical," in spite of which, however, we incline towards it.

Mr. Gosse, whose opinion is entitled to great respect, calls the *Euglenæ* "animals" in his "Evenings with the Microscope," but from the aggregate of recorded observations it seems that they evolve oxygen, are colored with the coloring matter of plants, reproduce their species in a manner analogous to plants, and have in some cases been clearly traced to the vegetable world. It is, however, possible that some *Euglenæ* forms may be animal, and others vegetable, and while their place at nature's table is being decided, they must be content to be called *Phytozoa*, which, as we have before explained, is merely *Zoophyte* turned upside down.

Some authorities have thought their animality proved by the high degree of contractility which their tissues evince. This, however, cannot go for much, as all physiologists admit contractility to belong to the vegetable tissues of the sensitive plant, "Venus' Fly-trap," etc., and a little more or less cannot mark the boundary between two orders of being.

Back Numbers and Volumes.

We can supply any back number or volume of the Young Scientist. One number (August, 1879) is now out of print, but, as the pages were electrotyed, we can easily reproduce them and will do so as soon we have taken stock of all the other numbers and know precisely what ones will probably be needed. The prices are: single numbers, six cents; volumes in loose numbers, fifty cents; volumes, neatly bound in cloth, with gilt titles on the back, $1.00 each. At these prices the volumes and numbers will be sent free to those ordering them. Postage stamps of small denomination will be received at full value for sums less than $1.00.

Correspondence.

Affection Among the Lower Animals.

Ed. Young Scientist—The enclosed paragraph is clipped from a generally reliable journal, but the story taxes my credulity somewhat. What do you think of it? MUS.

The following is the paragraph in question: "A gentleman, walking out in the meadows one evening, observed a great number of rats in the act of migrating from one place to another, which it is known they are in the habit of doing occasionally. Anxious to observe their movements, he stood perfectly still until the whole assemblage had passed close to him. Imagine his astonishment when he saw an old blind rat holding one end of a piece of stick in his mouth, while another strong and healthy rat held the other end in the same manner, and thus conducted his infirm and blind companion safely along the rough road they had to travel."

THE FAITHFUL GUIDE.

The story is an old one. We have even seen a picture of the occurrence, and have been so fortunate as to secure a copy, which we here present.

But notwithstanding the picture and the circumstantial account of the rats' proceedings, we very much fear the story had its origin in a vivid imagination rather than in actual facts. The anecdote frequently occurs in books; for example, it may be found in Porter's "Twenty Years' Recollections of an Irish Police Magistrate." Porter, however, ridicules the idea of its being true. The fact that the rats used a stick, which would not only have been a useless but an annoying encumbrance, staggers our faith in the story. We have heard of well authenticated instances of affection amongst the lower animals, quite as remarkable as the above would be if it were true.

Absorbing Pencils for removing ink blots are made by mixing 7 parts of plaster of Paris with 1 part of potato flour, moistening with the requisite amount of water, and casting into moulds. The pencils may be used for years.—*Indust. Bl., Vol. XVI., No.* 35.

Chloride of Magnesia (magnesium hypochloride), preferable to chloride of lime for bleaching fabrics, is now being manufactured cheaply from the latter, and magnesium sulphate obtained from the kieserite of Strassburg. The high price of production has until recently precluded the above article from general use in bleacheries.—*Indust. Bl., Vol. XVI., No.* 37.

SCIENCE IS KNOWLEDGE.

KNOWLEDGE IS POWER.

A PRACTICAL JOURNAL OF

HOME ARTS

VOL. IV. NEW YORK, NOVEMBER, 1881. No. 11.

Some of Ingersoll's Mistakes.

MATTERS relating to religion and politics do not come within the scope of the YOUNG SCIENTIST, not because we do not attach full importance to the momentous questions which arise within these departments of human thought, but because we propose to leave them to those journals to which they are specially appropriate, while we devote ourselves to placing before our young readers those practical applications and developments of science which will give both heads and hands something to do. It is not, therefore, with any of Col. Ingersoll's religious or theological utterances that we propose at present to meddle; these we leave to other hands. But Col. Ingersoll has assumed the position of an "advanced thinker" in science as well as in other subjects; in his writings we are constantly confronted with such expressions as "modern science;" "the science of the 19th century;" "modern scientific progress;" and this to such an extent that those who are not well informed in regard to the results of modern scientific research are almost led to believe that he knows something of science, at least so far as the elementary principles are concerned, whereas the truth is that in regard to the first principles of mathematics, physics and chemistry it is demonstrable that he knows absolutely nothing, or at least (which is the same thing) nothing that is of any value to himself or any one else. He has not even sufficient knowledge to enable him to read our most popular scientific authors, such as Tyndall, understandingly, and when he attempts to quote them from memory every sentence is misrepresentation and every statement a blunder. A single specimen of his mistakes, taken from his lecture which he calls "The Mistakes of Moses," is abundantly sufficient to substantiate all that we have just said. At

page 4 of the printed lecture we find the following: "I don't believe that he [the author of a certain passage in the Bible—Ed. Y. S.] knew that it [the earth] was turning on its axis at the rate of a thousand miles an hour, because if he did he would have understood the immensity of heat that would have been generated by stopping the world. It has been calculated by one of the best mathematicians and astronomers that to stop the world would cause as much heat as it would take to burn a lump of solid coal three times as big as the globe."

It would be very difficult for any ordinary writer to compress into the same space an equal amount of blundering. In the first place it does not "take" much heat to burn a lump of coal; after the coal gets to burning it produces all the heat that is wanted. Secondly, the earth does not turn on its axis at the rate of a thousand miles an hour; a narrow band round the equator has this velocity, but as we pass from the equator to the poles the velocity becomes less and less, until finally, at the poles, the velocity is slower than that of the hour hand of a watch. The mean velocity of the earth on its axis is that of the point which lies at the centre of gravity of a semicircle of which the earth's axis is the diameter.* This velocity is very nearly 438 miles per hour, or considerably less than one-half of that stated by Ingersoll. Thirdly, a velocity of one thousand miles per hour, if converted into heat, would not give anything like the temperature claimed for it by Ingersoll. He is confounding two entirely distinct motions, and his general knowledge of natural philosophy is not sufficient to enable him to detect his error.

That the mistakes we have pointed out are really blunders, any "mathematician and astronomer" can show. But as some of our readers may not be able to follow the calculations of the "mathematician and astronomer," we may cite the following simple illustrations: Railroad cars have been propelled at the rate of over a hundred miles an hour, and stopped in a very few seconds; did anyone ever observe that they became perceptibly hot to the touch when so stopped? and yet this is nearly one-fourth of the mean velocity of the earth on its axis.

Another illustration may be seen in fly wheels and circular saws. They have been made to rotate with a velocity nearly one-third that of the mean velocity of the earth on its axis. Did any one ever notice a dangerous rise of temperature when they were brought to rest? We have never observed any such thing, although we have had considerable experience in such matters. That motion can be converted into heat we know very well, but not to anything like the extent that Col. Ingersoll claims. Axles and bearings have been made hot by friction, but the extent to which they are warmed by changing from any ordinary velocity to a state of rest is scarcely perceptible to the keenest senses.

These and other mistakes have not been pointed out by our scientific men, simply because scientific men do not read Ingersoll's lucubrations. But as a teacher of the young in this department, the YOUNG SCIENTIST would fail in its duty if it neglected to point out the grossly erroneous character of the so-called "scientific" statements which have been so widely published by Col. Ingersoll.

*This point is readily found by the formula: Distance of c from axis = ·424 r.

Ornamenting Punches.

BY REV. J. L. ZABRISKIE.

IT may be interesting to young amateur turners of wood to have a hint on ornamenting their work by means of homemade punches.

One simple example is here given which may suggest an unlimited field for invention. Fig. 1 is the top view of a box lid of wood, cut across the axis of the cylinder from which the box is made, and thus causing the ornamental pattern to be impressed on the end of the grain of the wood. This surface so shown is not one continuous plane, but is formed of three planes, slightly rising one above the other. The narrow outer ring is the top view of a beading, which has been turned around the lid. The second broader ring, ornamented with the grape-vine pattern,

is elevated by a small step above the first, and also gradually rises towards the centre. And the inner circle, ornamented

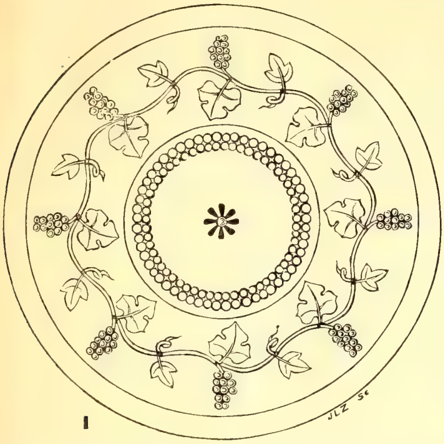

Fig. 1.—A BOX LID, ORNAMENTED WITH PUNCHES.

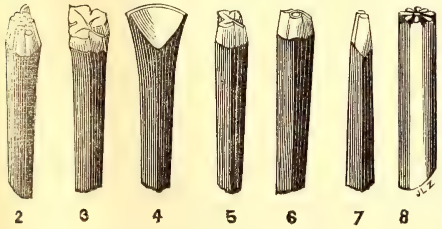
with a double row of minute rings and a rosette, is again elevated by a little step above the others.

Seven punches, which are shown in Figs. 2—8, are used in making this pattern. For convenience only about one-half of the length of the punches is here shown. These are made from ordinary eight-penny cut nails, with the exception of Fig. 8, which is made from a piece of stout wire. Either the head or the point of the



Figs. 2—8.—THE PUNCHES.

nail is used, according to the extent of punching surface required. Steel would be a better material for such tools. But common iron is much easier to work, and, even when used on hard wood, will stand a great deal of wear before being dulled or defaced.

Fig. 2 is a perspective view of the working end of the punch for making the bunch of grapes. It may be made in this manner: File off the top surface of the nail head smooth and true. With a small drill bore a number of shallow holes, close together, and arranged according to fancy, to form the grapes. Then, with a graver, or diamond-point tool, shown at Fig. 10, cut a moderately deep groove for the stem. And finally file away the iron, quite close up to the holes and groove, almost to a cutting edge. All the filing of this set of punches can be done with a three-cornered and a half-round file. The graver, of which the cutting end is shown at Fig. 10, is merely a small bar of square steel, hardened and ground with one face sloping towards one of the angles of the bar, so as to leave a lozenge or diamond-shaped surface, with a sharp cutting point and two cutting edges; and fitted with a suitable handle. On holding the punch to be cut in a vise, face up, and

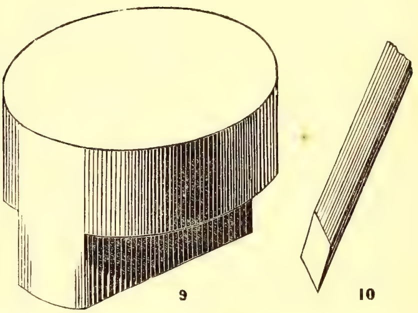


Fig. 9.—REST, FOR HOLDING BOX LID.

Fig. 10.—A GRAVER, OR DIAMOND POINT TOOL.

pushing the point of the graver, steadied by holding the tool with both hands, one will find that a little practice will enable him to engrave any ordinary lines desired on iron.

Figs. 3 and 5 are the punches for the two sizes of leaves of the grape vine. In making them, get a smooth surface on the top of the nail head; cut the veins and stem with the graver, and file away the outer portions of the iron to the desired shape.

Fig. 4 is the punch for making the vine. Engrave a semicircular groove rather deeply on the smooth surface of the iron,

and with a half-round or rat-tail file for the inside, and a flat file for the outside curve; file away the punch nearly to a cutting edge on either side of the groove. Such a groove in the punch will leave a projecting ridge on the wood, which looks much better than a mere indentation, which would be made if the surface of the punch were a solid segment of a ring.

Fig. 6 is the punch for the tendril. Cut the two curves deeply with the graver, and then file away the outside metal to correspond with the curves.

Fig. 7 is the punch for the double row of little circles. It is made on the point of the nail. Drill two shallow holes close together, and then file away the surrounding iron. And lastly, Fig. 8, for punching the central rosette, is made by drilling a shallow hole in the centre of the round iron, and then filing the gashes, and rounding the corners of the projections, to secure the desired shape.

In laying off the pattern, the main things to be attended to are to avoid breaking the box lid; to space off evenly the different parts of the design; and to secure an even depth of impression. Make a rest for holding the box lid, as shown at Fig. 9. It is a short cylinder of hard wood with a smooth upper working surface, which must be a little less in diameter than the inner cavity of the box lid, and having two pieces cut from the opposite sides of the lower end, leaving a tenon, which can be held in the vise. Place the box lid on this rest, in such manner that there shall always be a bevel and firm support directly under the punch.

Begin with punch Fig. 2. Place it perpendicularly on the surface of the lid, so that the small end of the bunch of grapes shall be near the point of the large circle, which is farthest from you, and strike the upper end of the punch with a hammer. If you are working on hard wood it may be necessary to strike two or three blows.

A little experience will show what depth of impression will give the best appearance. Now turn the lid half around on the rest, and punch another grape bunch at the opposite end of the diameter of the circle. Follow the same plan for dividing the circle into quarters. Then it will be an easy matter to divide it into eighths. Next punch the larger grape leaf, Fig. 3, allowing the leaf steam to slightly overlap the stem of the grape bunch. Then make the vine with punch, Fig. 4. It will be noticed that this part of the pattern is a reversed curve between each pair of bunches, which is made with two impressions from the same punch, by simply turning the latter half around, to get the desired direction of the curve. If the punch will not reach half way across the space between the bunches, the curve of the vine may be made longer by sliding the punch along carefully in the track of the impression just made, and then striking another light blow. Now make the impressions of the smaller leaf, and finally of the little tendril.

If all the impressions are made to slightly overlap each other, the final appearance will be better than it would be if small gaps were left in the design. The punching of the double border of little circles, and the central rosette, will be an easy matter after the vine pattern has been mastered.

This description may suggest a great variety of designs, as combinations of leaves, flowers, tendrils and other objects. And when the surrounding surface is finished with shellac and polished, such sunken designs give a very pleasing effect.

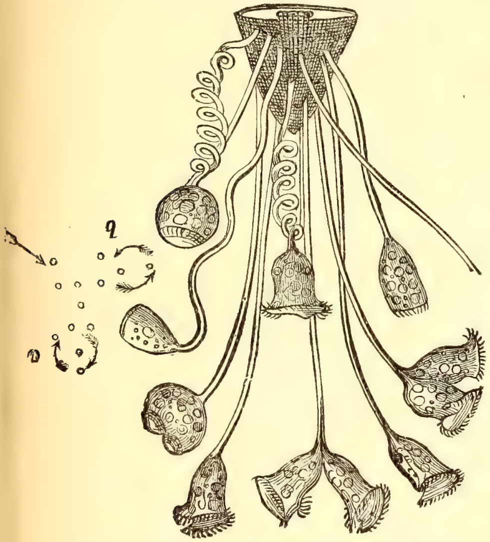
New Baltimore, N. Y., Aug., 1881.

Back Numbers and Volumes.

We can supply any back number or volume of the Young Scientist. One number (August, 1879) is now out of print, but, as the pages were electrotyed, we can easily reproduce them and will do so as soon we have taken stock of all the other numbers and know precisely what ones will probably be needed. The prices are: single numbers, six cents; volumes in loose numbers, fifty cents; volumes, neatly bound in cloth, with gilt titles on the back, $1.00 each. At these prices the volumes and numbers will be sent free to those ordering them. Postage stamps of small denomination will be received at full value for sums less than $1.00.

Marvels of Pond Life—III.

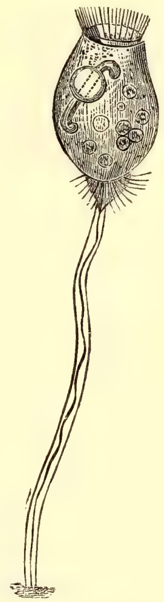
WE shall have occasion again to notice the *Protophytes*, and now pass to the *Protozoa*, of which we have a good illustration in the *Vorticella* already spoken of. In the group before us a number of elegant bells or vases stand at the end of long stalks, as shown in the accompanying engraving, while round the ends of the bells, the vibrations of a wreath of cilia produce little vortices or whirlpools, and hence comes the family name. This current brings particles of all sorts to the



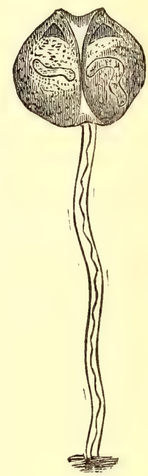
VORTICELLÆ, OR BELL FLOWER ANIMALCULES.

mouth near the rim of the bells, and the creature seems not entirely destitute of power to choose or reject the morsels according to its taste. Every now and then the stalk of some specimen is suddenly twisted into a spiral, and contracted, so as to bring the bell almost to the ground. Then the stem gracefully elongates again, and the cilia repeat their lively game.

The general effect can be seen very well by a power of about sixty linear, but one of them from one to two hundred is necessary to bring out the details, and a practiced observer will use still more magnification with good effect. They should be examined by a moderately oblique light, or most of the cilia are apt to be rendered invisible, and also by *dark ground* illumination. This may be accomplished in a well-made microscope by turning the mirror quite out of the plane of the axis of the instrument, that is to say, on one side of the space the body would occupy if it were prolonged. By this means, and by placing the lamp at an angle with the mirror, that must be learnt by experiment, all the light that reaches the eye has first passed through the object, and is refracted by it out of the line it was taking, which would have carried it entirely away. Or the object may be illuminated by an apparatus called a *spotted lens*, which is a small bull's eye placed under the stage, and having all the centre of its face covered



Vorticella, with posterior circlet of cilia in process of separation, 300 linear.—*Stein.*

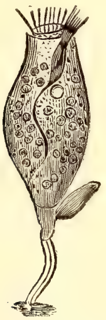


Vorticella in process of self-division. A new frontal wreath in formation in each of the semi-lunar spaces.

with a plaster of black silk. In this method the central or direct rays from the mirror are obstructed, but those which strike the edge of the bull's eye are bent towards the object, which they penetrate and illuminate if it is sufficiently transparent and refractive. Another mode of dark ground illumination is by employing an elegant instrument called a *parabolic illuminator*, which need not be described.

Different specimens and species of *Vorticellæ* vary in the length of their bells from one, three or four thousandth to one hundred and twentieth of an inch, and when they are tolerably large, the dark ground illumination produces a beautiful effect. The bells shine with a pearly iridescent lustre, and their cilia flash with brilliant prismatic colors.

The *Vorticellina* belong to the upper division of the *Protozoa*—the *ciliata*, or ciliated animalcules, and they have a mouth, an œsophagus, and an orifice for the exit of their food.



Vorticella microstoma, showing alimentary tube, ciliated mouth, and formation of a gemma at the base, 300 linear.—*Stein.*

Vorticella microstoma, the encysted animal protruding through a supposed rupture of the tunic.

Many observers used to ascribe to those creatures a complete intestinal canal, but such an apparatus is now believed not to exist in any of the Infusoria. Food particles, after leaving the œsophagus, are thrust forward into the sarcode, or soft flesh, and any cavity thus formed acts as a stomach.

The bells or cups are not, as might be fancied from a casual inspection, open like wineglasses at the top, but furnished with a retractile disk or cover, on which the cilia are arranged. Their stalks are not simple stems, but are hollow tubes, which in the genus Vorticella are furnished with a muscular band, by whose agency the movements are principally made.

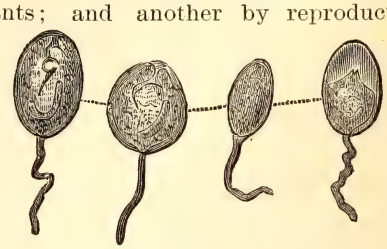
Some of the Vorticellids will be observed to leave their stalks, having developed cilia round their base, and may be seen to swim about in the enjoyment of individual life. They are also capable of becoming *encysted*, that is, of secreting a gelatinous cover.

Encysted Vorticella, showing the obliteration of special organs by the advancement of the process.—*Pritchard.*

These changes are exhibited in the annexed cuts, which are copied from known authorities. By careful observation of the bodies of Vorticellids, a contractile vesicle may be observed, which appears to cause a movement of fluids, that is probably connected either with respiration or secretion.

Another piece of apparatus in this family, but not confined to it, is the so-called *nucleus*, which in this case is of a horseshoe shape and granular texture, and greater solidity than the surrounding parts. The functions of this organ formed the subject of various conjectures, but it is now generally held to be an ovary.

In common with many of the lower animals the Vorticellids have three ways of multiplying their race. One by *fission*, or division of their bodies; another by *buds*, somewhat analogous to those of plants; and another by reproductive



Vorticella microstoma, in process of encystment, 300 linear; in the last the inclosing tunic is plainly developed,—*Stein.*

germs. These processes will come again under our notice, and we shall leave the Vorticellids for the present by observing that if they are fed with a very small quantity of indigo or carmine, the vacuoles or spaces, into which their nutriment passes, will be clearly observed. Ehrenberg thought in these and similar creatures that every vacuole was a distinct stomach, and that all the stomachs were

connected by an intestinal canal; hence his name, *Polygastrica*, or many stomached. In these views he has not been followed by later observers, and it is probable he was misled, partly by pushing the process of reasoning from the analogies of higher animals much too far, and partly by the imperfection of the glasses he employed.

How a Marine Aquarium was Started.

THE late W. A. Lloyd, Curator of the Aquaria in the Crystal Palace at Sydenham, England, gives the following graphic sketch of how he set up several marine aquaria in his early days. The account shows how difficulties which are at first sight insurmountable, may be overcome by thoughtfulness and labor. The following is his story:

There was a time, nineteen or twenty years ago, when not only shillings and sixpences were not to be thought of by me to be spent in aquarium matters, but pennies and halfpennies had to be laid out carefully. So, with artificial sea-water made from salts prepared by a Holborn chemist—which salts he kindly gave me, because I gave him the receipt for mixing them—I set up small aquaria in wide-mouthed glass bottles costing a penny or twopence each. The sea I had never seen, and was not so presumptuous as even to hope to see it, and I knew of no one living by the sea who could send me marine animals. But that daunted me not, for I used to sally forth at dead of night where heaps of oyster shells were thrown by day from street oyster-stalls in Smithfield and St. John's Street, and bring them home. The oysters devoured in such poor neighborhoods were not the genteel little smooth "natives," eaten at luncheon bars, but big rough "commoners," with bold foliations of the upper shell, and deeply ribbed on the lower one, and in and below these hiding places I could find many little sea anemones of several species, some hopelessly smashed, but others quite perfect (having been protected by the strong projections of the oyster shell), and unharmed by rain or other fresh water.

It was quite a mistake of the late Dr. George Johnston, of Berwick-on-Tweed, to say as he did, in his "History of British Zoophytes," that sea anemones are instantly killed by immersion in fresh water.

The species I found thus were *Actinoloba dianthus*, *Sagartia viduata*, *S. troglodytes*, *S. bellis*, and *S. elegans*, but very seldom the common *Actinia mesembryanthemum.*

All these I used to pick off the shells with never-wearying patience and care, and drop them into the factitious sea-water, and transfer them to my bottles, to which they adhered, and made themselves happy.

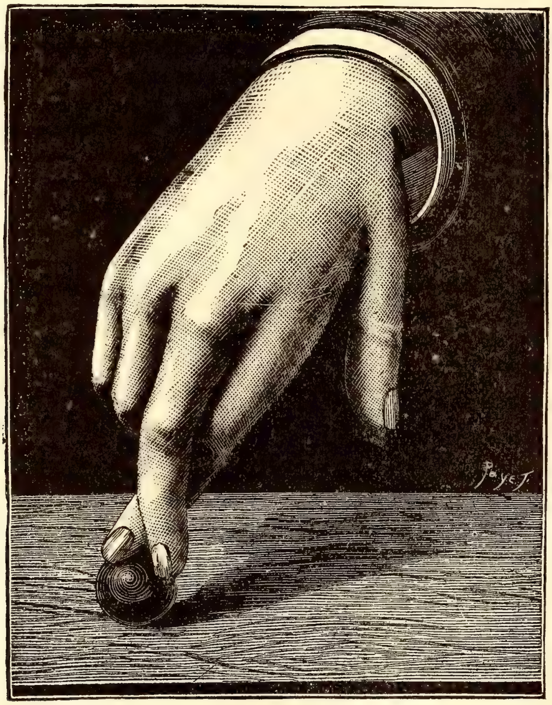
I used to feed them with little morsels of oyster-flesh which I found adhering to the insides of the shells, and when the water in the bottles would become offensive from the effects of the food, because the quantity of fluid was too small to hold enough oxygen in solution to decompose the dead animal matter fast enough, I poured the water from the little bottles into a great earthenware foot-pan covered with a sheet of glass to keep out dust, and standing in a dark corner of the room. The foot-pan was so very large in comparison with my small bottles, that the emptying of them periodically into the pan did not interfere with the purity of the water in the latter, so that from it I immediately re-filled the bottles one at a time, on successive days. The water in the foot-pan on the floor below thus effectually counteracted all tendendy at going wrong in the bottles on the window sill above.

—Certain timbers of great durability, when framed together, destroy each other. A large black walnut log, framed into a cypress gallows-tree, under shelter, both perfectly sound, in two years were discovered so badly decayed as to prevent the use of the cypress again. The walnut sawed off remained sound ten years, while the lower end of the gallows-post, where cypress was joined into cypress, remained as sound as the day it was put together.

The Ilusions of Touch.

WE all know the deceptions to which we are liable from illusions of sense. The skilful ventriloquist finds no difficulty in deceiving our sense of hearing, and the errors which we make when we trust to our sense of sight are like the auctioneer's catalogue—"too numerous to mention." Our sense of touch, however, has hitherto maintained a character above reproach; when we are in doubt as to the reality of anything which we see, or even in regard to its shape, consistence or number, an appeal is at once taken to our sense of touch, and when "we have felt it," argument is at an end.

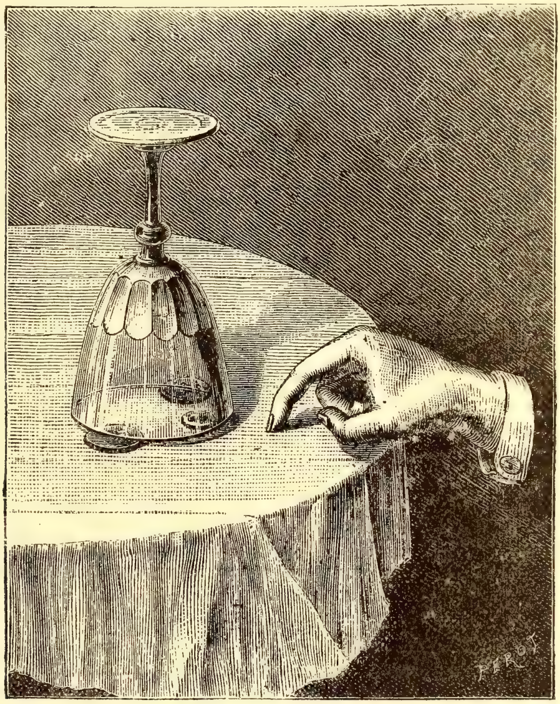
But even this severely accurate sense is liable to deception, as the following simple experiment will show: Take a pea or a small marble or bullet, and place it on the table or in the palm of the left hand. Then cross the fingers, as shown in the engraving, the second finger crossing the first, and place them on the ball, as we have figured it. If the pea or ball be now rolled about, the sensation is apparently that given by two peas under the fingers, and this illusion cannot be dispelled by the aid of the other senses, as is usually the case under similar circumstances. We may try and try, but it will be only after considerable experience that we learn to disregard the apparent impression of two objects.



ILLUSIONS OF TOUCH.

The explanation is simple enough. In the ordinary position of the fingers the same ball cannot touch at the same time the exterior sides of two adjoining fingers. When the two fingers are crossed the conditions are exceptionally changed, but the instinctive interpretation remains the same, unless a frequent repetition of the experiment has overcome the effect of our first education on this point. The experiment, in fact, has to to be repeated a great number of times, to make the illusion become less and less appreciable.

It is easy to perceive that in the domain of the sense of touch the judgment, being formed instinctively, finds itself at fault when the normal conditions are modified; thus it happens, for example, when we have on the lips an accidental pimple or swelling, the glass from which we drink appears to have a distorted edge.



CURIOUS MECHANICAL PUZZLE.

Facts of this nature are very interesting to study from a philosopical point of view, for they demonstrate that the judgment which we form in regard to external material realities is based upon the interpretation of our sensible impressions. The impression of our senses is something entirely physical, and in no wise psychological. Interpretation is an affair of habit and education.

— The first telegraph line was erected less than 40 years ago, and now 1,000,000 miles are in operation.

A Curious Mechanical Puzzle.

THE following puzzle always affords considerable amusement when first shown. Place a ten-cent piece on a table which is covered with a cloth or napkin, and over it place a tumbler or goblet, supported by two twenty-five cent pieces, as shown in the engraving. Thus arranged, the question is how to make the ten cent piece issue from beneath the goblet without touching the latter, or pushing it or drawing it out by means of some other object. To succeed in doing this it is merely necessary to scratch the table cloth or napkin with the nail of the forefinger close to the goblet, when, through the elasticity of the fibres of the fabric, motion is transmitted to the ten-cent piece, which, in consequence of its inertia, begins to move towards the finger, and escapes of itself from its prison.

A QUERY.

BY MARY H. WHEELER.

Down, down in the pool where the cypris is swimming,
  And the *Daphnia pulex* darts swiftly from sight,
Where the pink fairy-shrimp o'er *confervæ* is skimming,
  And the floscule extends her five lobes to the light.
Where the *Candona lucens*, a wandering gem,
  Creeps along a *desmidium* band,
And the fair vorticella, on sensitive stem,
  Is contracting, again to expand.
Do the small creatures know, in their homes in the ditches,
  That the dark, stormy winter is near?
And, O, what will they do, in their cold crystal niches,
  Through the long silent night of the year!

When the wee *tardigrada* is chilled into quiet,
  And the sphere of the volvox no longer is seen,
When the long-toed *dinocharis* quitteth her diet,
  And the shining Zanthidium loses its green;
When the bright hyalotheca, faded and limp,
  Lies all tangled with ulothrix bands,
And the slender synedra and staurastrum jimp
  Shall drop down to be blent with the sands,
Will the small creatures know any changeful emotion,
  Any feeling resembling our joy or our fear,
Or excitement of which human nerves have no notion,
  Through the long, silent night of the year?

Pittsfield, N. H., Oct. 25.

Care of Oil-Stones.

THE oil-stone is such an important tool in every mechanic's and amateur's workshop, that the greatest care should be taken to keep it in good order. Outside of the shops of skilled mechanics and thoroughly good amateur workers, the oil-stone is generally an unsightly and useless nuisance. Covered with gummed oil and dirt, and hollow and uneven on its surface, it is a very unsatisfactory article to work with. We know one shop where an oil-stone is used occasionally, but not enough to lead the owner to make a point of keeping it in order. He has, perhaps, a dozen which have been thrown to one side as useless, simply because they are covered with thickened oil—gummed up, as mechanics call it. As soon as the stone refused to cut the metal, it was thrown aside as useless, and a new one procured. The owner readily gave us, for the asking, one or two of these old, and, as he thought, useless stones, and we gave him a little information and advice which probably enabled him to put all the stones on his premises in order.

The first thing to do is to clean off the dirt. This is best done by means of common washing soda. Soak the stone in a strong lye for a few hours, and then rinse it off in clean water, and wipe it clean. If the stone has not been worn so as to make the surface hollow or uneven, the only thing that will be needed is to apply a little good oil. The stone will then be found to cut freely, and will be as good as new. But if the surface has been *glazed* by being used without oil, or by being used very much with oil that has become quite gummy, the stone must be refaced. The best thing for refacing stones, where it can be had, is a plate of cast iron, smeared with emery and kept moist with water. This will cut the stone very fast, and will bring out its cutting properties very thoroughly. The cast iron plate should be planed or ground, so as to make it quite level, and take the skin off. Instead of a cast iron plate, a piece of thick sheet zinc makes a very good grinder. The emery should be fine, and plenty of water should be used. Even a sheet of glass paper or emery paper, laid

evenly on a board, and used dry, will renew the surface of an ordinary oil-stone. Or a block of sand-stone, which has been dressed straight, will do. The following plan has been highly recommended by a correspondent of the *Scientific American*. He says: "I have, in the course of my life, spent a good deal of time in facing off my oil-stones. I have used sand on a board, wet and dry, or an old millstone, or a hard brick. If the oil-stone was soft, it could be cut or rubbed down in a short time; but if a hard one, it was a serious job. The thought struck me, about two years ago, that emery would be the thing to quickly cut a hard stone which I have. I dressed off a white pine board, put a thin coat of glue on it, when dry put on another, sprinkled coarse emery on the glue, rubbed it in well, and when dry put on another coat of glue and emery. I have been using it ever since; it does not take one-tenth of the time to face off that stone that it formerly did with sand, etc. This may save some one some hard rubbing."

When a stone has once been brought into good condition, try to keep it so. Never use it without a liberal supply of good oil, which *must* be of some non-drying kind, if you would keep the stone in order. Olive oil or sperm oil is what we use. We have tried soap, glycerine, kerosene, etc., etc., but find that although they work well for a few minutes, they soon spoil the stone. As soon as you have finished your work, wipe the stone off clean, and cover it up to keep it from the air. The best way is to keep it in a wooden case, carefully fitted to it, but when the stone has no case, wrap it carefully in several folds of paper. No stone will do good service unless the surface is kept even and straight; therefore avoid using the middle of the stone more than the ends, and as soon as any part gets worn below the general level, have the whole surface dressed off even.

—Iridium is the least fusible of all metals, requiring a temperature of about 3500° Fahr. Platinum melts at about 3200° Fahr.

Editorial Notes.

Our January Number.

THIS will contain several finely illustrated and interesting articles, including a handsome frontispiece, which illustrates a very singular experiment. The article on Pond Life will be continued, and there will be articles of great practical value on the Aquarium, the Turning Lathe, Makeshifts for Young Microscopists, etc., etc. The first of a series of three articles on Cutting and Engraving Glass. This series will include a very simple arrangement for the sand-blast. Our young friends should be careful not to miss this number.

A Word to Our Subscribers.

THE present year is drawing to a close, there being but one more number to be sent to each subscriber. That number will contain index and title page, so that those who wish to have their journals bound can have a complete book.

For the coming year we have made such arrangements as we believe will enable us to give our readers better satisfaction than ever before. It is our purpose to steadily improve the YOUNG SCIENTIST, and we intend that every number shall be better than those that have preceded it. That we may be able to do this, however, we must secure the help of our subscribers. We ought to have a subscription list double what we now have—at least fifteen thousand—and we can easily do this if our friends will only help us. Let each one of our subscribers send in a new name and the thing is done. But remember we do not ask you to do this for nothing. We are willing to pay, and pay well, for this little service, and therefore we make the following liberal offer, which will hold good until the 25th of December, Christmas day. Those who wish to work for money, may retain fifteen cents out of the fifty received for every *new* name they send us. Those who wish books, can have twenty-five cents worth of any of *our own* publications for every fifty cents that they remit for a new name. Thus

four new names would secure Pemberton's work on Drawing, or Phin's large book on the Microscope. Three new names will secure Shooting on the Wing, or The Steel Square. One name and ten cents will secure a copy of the Workshop Companion—a book which contains more for the money than any other volume that we know of. For other premiums we refer to our advertising pages.

Electrical Humbugs.

THE wonders which can be actually performed by electrical agencies are so marvellous that it is no wonder that the public in general have unlimited faith in the powers of this force. In the presence of the telegraph, the telephone, the electric light and a dozen other successful applications, he would be a bold man who would pronounce against the possibility of any achievement. This fact does not, however, prevent us from deciding against certain obvious humbugs and swindles which are to-day too common. Electricity has its laws as well as gravitation, and the man who proposes a scheme to which they are obviously opposed is either a fool or a knave. Some of the swindles which are now before the public are exceedingly barefaced, and yet they are wonderfully successful in drawing the money out of the pockets of the people, and the most emphatic testimonials from "respectable" clergymen. One man sells a hair-brush for which is claimed all the virtues under heaven—all due to electricity. To convince the gullible portion of the public that the brush has great electrical power, those who sell it exhibit its action on a magnet, and as the brush is apparently made of non-magnetic material, the effect is supposed to be due to the electricity which is somehow stored in the brush. The fact is, however, that there is a small steel magnet concealed in the substance of the back of the brush, and it is to this that the action is due.

Others present to the public what they call magnetic or electrical garments under various names. What adjectives are too strong to characterize the fraudulent claims made for these articles? That electricity is a most valuable remedial agent when properly directed and judiciously applied there can be no doubt. But these men know nothing either of electricity or medicine; all they want is money, and they make up for the lack of knowledge by the most unblushing assurance and the most lying claims. The articles which they sell, violate the most elementary principles of natural science, and our young readers are cautioned to beware of them. The most astonishing thing is that their advertisements are admitted into professedly scientific, and even into some medical papers, thus lending to them a *quasi* endorsement which no respectable paper should give even in its advertising columns.

Death of Charles A. Spencer.

THIRTY years ago the scientific world was thrown into a ferment by the announcement that "an object-glass, constructed by a young artist of the name of Spencer, living in the back woods, had shown three sets of lines on a very delicate diatom, when other glasses of equal power, made by the first English opticians, had entirely failed to define them." This passage, which marks an era in the history of the microscope, occurs in the first edition of Quekett's work on the Microscope, but has been expunged from subsequent editions. At that time Ross had declared that an angle of aperture of 135° was as great as could be given to the object-glass of a microscope. Spencer, with a true American unbelief in the impossible, went to work, and in a short time succeeded in making glasses having an angle of aperture of 172°, and since that time the angle has gone on increasing, its increase being an accurate indication of the advancement of microscopy. Spencer was an entirely self-taught optician, and his talents and success made American microscopes known all over the world. He died at Geneva, N. Y., on the 28th day of September, 1881, at the age of 68 years.

A fine portrait of Mr. Spencer, together with a lengthy biography, will appear in the forthcoming number of the *American Journal of Microscopy*.

Correspondence.

How to Sharpen a Pencil.

Ed. Young Scientist—In your prospectus you say that the YOUNG SCIENTIST is for teaching us *how to do things*. Now, I would like very much to know the best way to sharpen a pencil. Papa has bought me two or three pencil sharpeners, but they are no good. When I use a knife I dirty my hands up, and the point of the pencil breaks, and it is just awful. Please tell me how, and also what is the best sharpener, and I will thank you ever so much. Yours,

A LITTLE GIRL.

The experience of our young friend is the same as our own; we have never found a pencil sharpener that we would accept as a gift. The best pencil sharpener is a good sharp knife, and with it, it is easy to give a pencil either the round, conical point used for writing, or the flat, chisel point used for drawing lines.

First of all, remove the wood with a series of long clean cuts; do not hack and nibble it, making it look as if the rats had eaten off the end. This requires a sharp knife, and, if your hand is large enough, the best way to hold the pencil is to lay the end on your thumb, and hold the knife in the four fingers. If your hands are small you had better hold the pencil in the left hand, point outwards, and cut away from you; in this way all danger of cutting yourself is avoided. Do not attempt to cut the lead until you have cut away the wood so as to leave about one-eighth of an inch exposed. As the lead is quite brittle it must be supported, and most persons lay it on their thumb, allowing the powdered black lead to fall all over their hands, soiling them in a very disagreeable manner. In addition to the dust, however, the point of the pencil is very apt to be broken, since the flesh is soft and yielding. Therefore, the best plan is to lay a piece of paper on a table or board, and on this lay the point of the pencil, flat. You can now shave off the black lead without any risk of breaking it, and by constantly turning the pencil round, a beautiful conical point may easily be given to it without in the least degree soiling the hands or anything else, except the waste paper, which may be thrown away.

To carry out these directions, however, it is necessary to have a sharp knife, and one of which the blade is not too soft. Draughtsmen and engravers frequently use a file or a piece of fine sand-paper for sharpening pencils, and they answer admirably. But after all we prefer a good sharp knife.

BOOK NOTICES.

Trichinæ (Pork Worms, or Flesh Worms): How to Detect Them and How to Avoid Them. Being a Popular Account of their Habits, Modes of Propagation, and Means of Dissemination. Intended for the Use of Farmers, Butchers, Pork Dealers, and Consumers of Pork. By John Phin, Editor of the *American Journal of Microscopy*. Rochester: The Bausch & Lomb Optical Company.

This little pamphlet has not been written from an alarmist standpoint, although it points out clearly and forcibly the danger to an important article of commerce if steps be not taken to stamp out what a German author calls "man's most dangerous enemy." So far as human beings are concerned, it has been clearly shown that we have, in the simple process of *thorough* cooking, a perfectly efficient means of killing trichinæ and all other parasites. But in order to be effectual, the cooking must be *thorough;* no mere surface scorching on the one hand, or brief dipping in boiling water on the other. It has long been known that a lump of flesh, placed in boiling water, may be very thoroughly cooked on the outside, while the interior has not reached a temperature high enough to destroy any parisite that may be present. And if this process of cooking be applied to all animal food given to pigs, dogs and cats, and if it be made a serious offence to manure with animal offal, land on which are to be grown grass or vegetables that are eaten in a raw state, the trichinæ would soon be "stamped out."

This pamphlet, which may be obtained free from the Bausch & Lomb Optical Company, of Rochester, N. Y., gives very clear engravings, showing the trichinæ at its different stages, and it also describes a very simple and efficient instrument for detecting the pest.

Practical Hints on the Selection and Use of the Microscope: Intended for Beginners. By John Phin. Editor of the *American Journal of Microscopy*. Fourth Edition. Thoroughly Revised and Greatly Enlarged. Illustrated with six plates and 80 figures in the text. New York: Industrial Publication Co.

It is but a short time since we noticed the issue of the third edition of this work, and yet that edition is already exhausted and a fourth published. Some additions have been made to this edition, and the work is now so large that the publishers no longer find themselves able to sell it for seventy-five cents. The price has therefore been raised to one dollar. While it never can prove a substitute for the larger works of Beale, Carpenter, or Frey, it has shown itself to be a most useful volume for the beginner and the amateur.

The Rain Drop: A Monthly Miscellany of Entertaining Reading for Young People. Pittsburgh, Pa.: James Logan.

We have frequently noticed this interesting journal during the course of its publication, and now that it has closed its career, we call attention to it as one of the very best Christmas gift books

within our knowledge. The matter does not consist of mere clippings, but of carefully edited matter, which is of real value both to old and young. Here we find the Romance of Reynard the Fox, which will interest the little folks for its story, and the older people for its folk-lore, and the many allusions which have been made to it in the better classes of literature. Every member of the family will find something in it; the little ones lisping for a story will find Jack the Giant Killer and John Gilpin; older ones will find the story of Romulus and Remus, and still older ones may read with pleasure, as we have done, the Romance of Reynard the Fox and the story of Robin Hood. The book forms a handsome quarto of nearly 400 pages.

E. & F. N. Spon have now ready a Descriptive Catalogue of Books for Mechanical Engineers, and will send it free, on application. Address 446 Broome Street, New York.

An Ingenious Æolian Harp.

In a former number of the YOUNG SCIENTIST we gave very full directions for constructing an æolian harp, and our readers will no doubt be interested in the following account of a rather complicated but very ingenious instrument of this kind. It seems that some time ago a son of Mr. George Ellwanger, of Rochester, N. Y., while traveling in Germany, became impressed with the agreeable combinations of tones produced by æolian harps, and, on returning home, mentioned the circumstance to his father. The latter soon conceived the idea of erecting an æolian harp on his tower near Mount Hope. A suitable man to make the instrument was found in Professor C. Dennebecq. The sounding-board is to be of Norway pine, seven feet high, and the back of hard curled maple of forty-five years' cut. These woods are all imported, the slow growth of European woods giving them a texture better adapted to musical instruments than the home products.

As a whole, the instrument is to be tube-shaped, with eight slots in the tube. The latter is to be surmounted with a lightning rod, eight feet high, with a weather-cock attached. Right here is where Professor Dennebecq introduces a new design of his own; for with every turn of the weather-cock a slot is presented to the wind and a string is made to vibrate. The first string that is made to vibrate in this manner gives the fundamental note, while the other will sound a third and give the acute octave to the first. Prof. Dennebecq has no doubt as to the success of his instrument, and thinks when completed and placed on the tower it can be heard on still nights for a distance of three miles up the river. He made a similar instrument for the Sorbonne in Paris, which, however, is not automatic, but must be arranged by the janitor before it will work.

The constructor of these instruments is a pupil of the celebrated Villaume, and gave three years of his life to learn the trade of repairing his own violin. This violin was one of Steiner's make, who was a pupil of Amati, and whose violins have a reputation that is world-wide. Prof. Dennebecq himself has acquired a reputation as a violin maker and restorer, and is conversant with the mechanism not only of this, but of several other musical instruments.

Before leaving the subject we may mention the colossal harp erected at Milan in 1786 by the Abbe Gattoni. He stretched seven strong wires, tuned to the notes of the gamut, from the top of a tower, sixty feet high, to the house of a Signor Moscate, who was interested in the success of the experiment. This apparatus, called the "giant's harp," in windy weather yielded lengthened peals of harmonious music. In a storm it was sometimes heard at a distance of several miles.

In many places where the telegraph wires are strained sufficiently tight, these structures form gigantic æolian harps. As a general rule, however, they are not strained tight enough to give a full sound, and they have no sounding boards.

The Toad.

The whirligig of time brings about strange revenges, and among them may be noted the recent accession into favor of the long-despised and much-maligned toad. For centuries these harmless animals have been persecuted and reviled till their very name has passed into a byword descriptive of disgust and loathing. At last, however, their unobtrusive virtues are obtaining recognition, and the value of the unhandsome toad as an insect destroyer is now generally admitted. At the present time a "toad market" is held regularly in Paris, once a week, on an open space of ground in the Rue Geoffrey St. Hilaire, at the back of the Jardin des Plantes, whither the dealers in this novel article of commerce bring their wares, carefully assorted according to their strength and size, and packed by the hundred in baskets of damp moss. Whence the supply may be derived is as yet a mystery, but it seems clear that they are not over-abundant, since those of moderate size find ready purchasers at prices ranging from seventy-five to eighty francs per hundred. By far the greater portion of them are bought up for the use of English market gardeners, and it is stated that orders are to hand at Paris for the purchase, at current rates, of every basketful sent to market.—*London Farmer.*

Improved Carmine Ink.

The solubility of carmine lake in caustic aqua ammonia is attended with this disadvantage; that in consequence of the alkaline properties of ammonia, the cochineal pigment will, in time, form a basic compound, which in contact with a steel pen no longer produces the intense red, but rather a blackish color. To avoid this evil, prepare the ink as follows: Saturate 1 gramme of pure carmine with 15 grammes of acetate of ammonia solution and an equal quantity of distilled water, in a porcelain mortar, and allow the whole to stand for some time. In this way a portion of the alumina which is combined with the carmine dye, is taken up by the acetic acid of the ammonia salt, and separates as precipitate, while the pure pigment of the cochineal remains dissolved in the half saturated ammonia. It is now filtered, and a few drops of pure white syrup added to thicken it. In this way an excellent red drawing ink is obtained, which holds its color for a long time. A solution of gum arabic cannot be employed to thicken this ink, as it still contains some acetic acid, which would coagulate the bassorine, which is one of the natural constituents of gum arabic.—*English Mechanic.*

Practical Hints.

Red Oak as an Ornamental Wood.—Red oak is found in abundance in almost all parts of the country, and from its plentifulness and its unsuitableness for a large majority of the commercial uses to which white oak is utilized, has been looked upon with a contempt, but little deserved when its adaptability to the manufacture of furniture is taken into consideration. It is more brittle than white oak and more porous, and this has probably been the cause of its neglect for shipbuilding purposes, combined with the fact that it is more susceptible to the attacks of the marine insects which abound in salt water. It is not a wood which will stand the variations of wet and dry; and while white oak was to be had in abundance, the red oak was thought fit only to be made into flour barrels. When sawed bastard, so as to fully develop the grain, there is no question of its beauty being equal to black walnut, in the eyes of those who are not prejudiced in favor of the rich dark color of the latter.

Fine Linen.—According to the *Building News*, a piece of linen has been found at Memphis containing 540 picks to the inch, and it is recorded that one of the Pharaohs sent to the Lydian king, Croesus, a corselet made of linen and wrought with gold, each fine thread of which was composed of 360 smaller threads twisted together! The ancient Egyptians wove a linen called the "linen of justice," or "justification." So beautiful and valuable was it that it was esteemed the most acceptable offering to the "Restorer of Life." A few hand looms can be seen at work in the Eastern bazaars of Cairo, the cloth woven in which rivals in texture, color and design the finest glass screens of Munich.

Improved Varnish for Special Purposes.—Moreau, of Paris, patents the following improved varnish: Infuse 195 grammes of gum sandarach in one-fourth litre spirits of wine; also 120 grammes spirits of turpentine in three-fourths litre spirits of wine. Stand the two infusions in a water bath for half an hour; then mix, and place the mixture in the water bath for fourteen minutes more. Allow it to stand for twenty-four hours, and filter through cotton. The result is a colorless varnish, which may be given any desired tint with saffron, Prussian blue, indigo, etc. The patentee states that the effects resemble those formerly produced by the famous "Vernis Martin," the secret of which is now lost.

A New Cake Tryer.—A broom splint has occupied a prominent position among aids to cooking for an indefinite period of time, and housekeepers who are immaculate in all other matters often take a splint from a broom with which they have perhaps swept the kitchen, and "try" a delicate cake with it. A much better way is to buy a cheap little "brush broom," and keep it for this and no other purpose; one will last a lifetime; hang it in the dining-room near the kitchen door. If so disposed you can make a pretty case for it of fancy paper or Turkish towelling, then one will not be tempted to use it for anything else in the kitchen.

Fine Drilling.—Professor Edward C. Pickering, of Harvard College, says that in undertaking to measure the intensity of the light of the satellites of Mars, he had occasion to need an extremely small hole. Among the artisans who essayed to furnish what was required was one who had succeeded in making a hole edgewise through an old fashioned three cent piece, and another who had pierced a needle through from end to end. A hole about the twenty-five hundredth part of an inch in diameter was finally secured.

Cheap Pencil-mark Eraser.—Caoutchouc is dissolved in carbon disulphide, the solution is intimately mixed with enough starch flour to form a dough, and exposing the mass, in suitable pieces, to the air, until all odor of carbon disulphide has disappeared. The product is an excellent eraser for lead pencil marks from paper. If, in addition to starch flour, finely powdered pumice stone be added to the mass, it will be suitable for erasing ink marks or writing from paper.—*New Remedies.*

Blue Ink.—Take Berlin blue, 6 parts; oxalic acid, 1 part. Mix thoroughly into a soft paste with water. Dissolve in rain water, and add a little gum arabic.

QUESTIONS AND ANSWERS.

Drilling Glass.—In the number of the Young Scientist for August, 1880, page 100, you give a short note on "Drilling Glass," and tell us how *not* to do it. Will you please tell us *how* to do it?

Ans.—There are three ways of drilling glass: One is with a diamond drill; the second is with a soft metal drill charged with sand or emery, and the third is by means of a steel drill. A hard steel drill, lubricated with sulphuric acid, or with camphor dissolved in turpentine, will cut glass very rapidly. We have frequently bored a hole a quarter of an inch in diameter through a thick plate of glass by means of such a tool. The diamond drill, for holes over a quarter of an inch in diameter, consists of an iron tube with splinters of diamond firmly stuck into holes bored on the outer and inner edge of the tube. For small holes an iron rod charged with diamond powder answers well. Copper drills, made either of copper rod or copper tubing, according to size, answer well. They are kept charged with emery or sharp sand and water, and the drill should be guided by a block of wood cemented to the glass. The wood has a hole bored through it the exact size of the drill. This hole is placed exactly over the spot where the proposed hole is to be, and prevents the drill from slipping about.

Power of Eye-pieces and Objectives.—Can you tell me what is the standard of power for the different objectives marked A, B, C, D, E, etc.? I have a microscope with very good objectives and eyepieces, marked A and C, and I feel satisfied that the objectives will give good definition with much higher magnifying power than I now get. What power will I get if I procure a D eye-piece?

Ans.—The values of the different eye-pieces vary with different makers, and this to such an extent that unless we knew who was the maker of your microscope we could give you no accurate information on the subject. The eye-pieces made by Ross twenty years ago, as given by Brooke, were as follows:

Name of Eye-piece.	Focal Value.	Magnifying Power.
A	2·7 inch	3·7 times.
B	1·6 "	6 "
C	1· "	10 "
D	·6 "	17 "
E	·4 "	25 "

and this scale seems to have been pretty closely followed by most makers. So that a D eye-piece on the above scale would give you a magnifying power rather more than one and a half times what you now get.

EXCHANGES.

Only those who are *yearly* subscribers, and whose names are entered on our books have the privilege of inserting exchanges.

Exchanges must be on separate slips of paper or postal cards. If mixed with business letters or cards they cannot be used.

Exchanges must not exceed thirty words.

Buying and selling belong to the advertising department.

We reserve the right to omit the exchange column, when we have not room for it, and the amount of space at our disposal will regulate the number of insertions given to each *exchange*, the preference being always given to those who have not previously used our columns.

Magic lantern, in good order, condensing lens, 2½ in. diameter, 8 slides. For small photographic camera or offers. H. A. Giddings, 4 Union Place, Classon Ave., Brooklyn.

Fifty canary birds, with and without crests; fancy poultry, conch shells, strombus alatus. For small printing press, books on natural history, or offers. Frank Lattin, Gaines, N. Y.

Printing press, type, etc., worth $13, for offers. E. G. Vogeley, 1010 Bradford St., Pittsburgh, Pa.

A good plain 7 shot revolver, 22 calibre, for a Students' inch or half-inch objective. Frank F. Colwell, Urbana, Ohio.

Wanted, Printing press and type, in good order, chase 6 x 10, or larger; will give hardware, tools, scroll saw, or designs. Chas. E. Little, 59 Fulton St., New York.

Photo outfit, tools, chemicals and apparatus, etc., etc.; wanted scientific books, apparatus, etc.; send lists. A. B. Campbell, Box 59, South Dayton, Catt. Co., N. Y.

Stuffed birds, insects or job printing (cards, labels, etc.) for mounted objects for the microscope. James P. Melzer, Milford, N. H.

A ring stand, filtering stand, calcium light jet and a gas holder, holding one cubic foot, for a phonograph. D. P. Smith, 59 Park Place, New York.

To exchange, Hugh Miller,s "Cruise of the Betsey," and "The Old Red Sandstone," cloth bound geological books, for lathe, hammock, or "Gray's Manual of Botany." Gus. C. Spaeth, Mt. Carmel, Ills.

F. F. F., Lock Box 83, St. Johnsbury, Vermont, would like to exchange or correspond with persons interested in mineralogy, Oology, philatology, Indian relics, books, entomology, numismatology, etc.

Wanted, a good printing press and type; state what is wanted in exchange. H. A. Kinney, Hamlin, Brown Co., Kansas.

I have a printing press and outfit (cost $15) to exchange for books, microscope, tent, watch, or offers. Henry E. Jacobs, 59 Harvard Street, Boston, Mass.

I have Vols. 2 and 3 of "Nests and Eggs of American Birds," to exchange for Vol. I of Young Scientist, or offers. N. B. Stone, Lock Box 9, Putnam, Conn.

Wanted, a printing outfit or offers, in exchange for baritone cornet, air gun, and other things, a list of which will be furnished upon application. E. S. Nixon, Jr., Box 345, Chattanooga, Tenn.

To exchange, minerals, ores, shells, papers, magazines, books, coins, stamps, for stamps, coins, minerals, stylographic pen, telephone, etc. A. M. Beveridge, P. O. Box 854, Appleton, Wis.

Will exchange minerals for other minerals; state what specimens you desire. E. A. Refsnyder, Phœnixville, Chester Co., Pa.

Wanted, a good powerful second-hand microscope; forward engraving of instrument, stating price, or what is wanted in exchange. L. D. Snook, Barrington, Yates Co., N. Y.

Wanted, botanical specimens of Western, West Coast, and Southern ferns, in exchange for Northern species; lists exchanged. H. N. Johnson, Coeymans, N. Y.

Wanted, copy of "Snowball's Elementary Natural Philosophy." M. B Tausy, Harrisburg, Pa.

A new 2 x 4 engine, worth $60, for a first-class bicycle; also a watch, revolver, and gas stove, for a 6 x 9 printing press, type, or offers. Geo. L. Lamson, La Fargeville, N. Y.

To exchange, specimens in botany, oology, etc., for those in other localities; botanical correspondents desired. Arthur Fairbanks, St. Johnsbury, Vt.

To exchange, for other books on scientific and industrial subjects, "Moore's Universal Assistant," "The Young Mechanic;" both quite new. Fred. Whitehead, Box 55, St. Augustine, Fla.

A German microscope, with 3 objectives and 5 eye-pieces, condensing lens, etc., resolving Pleurosigma angulatum, will be exchanged for a first-class spectroscope. Clarence L. Speyers, 50 West 17th St., New York.

I have a fine concert harmonica, 20 notes, with case, but little used, that I will exchange for Vol. 3, of the Young Scientist. Charlie O. Wells, Hatfield, Mass.

To exchange, birds' eggs and minerals, for minerals, ores, and curiosities. H. G. Emery, 51 Spencer St., Albany, N. Y.

THE

Young Scientist.

CURIOUS EXPERIMENT ON INERTIA.

THE Young Scientist

SCIENCE IS KNOWLEDGE.

KNOWLEDGE IS POWER.

A PRACTICAL JOURNAL OF

HOME ARTS.

VOL. V. NEW YORK, JANUARY, 1882. No. 1.

Illustration oı Inertia.

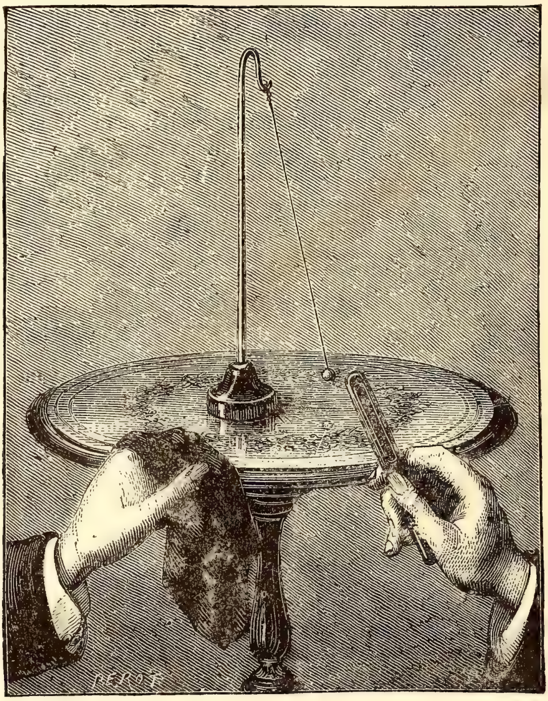
A CURIOUS experiment is sometimes performed by itinerant physicists, and which may be described as follows: A broom handle is laid horizontally on two annular bands or rings of paper. Then two boys are selected, and each having been provided with a razor, they are required to support the broom handle with these, the cutting edge of the razors being uppermost and in contact with the intervening paper. All being in readiness, the operator takes a stout stick, and, with all his strength, strikes the broom handle in the middle, when, much to the surprise of the spectators, the latter is broken into slivers, while the paper bands which supported it are not even cut by the razors. The experiment which is figured in our frontispiece, and which is based on the same principle, may be performed as follows: First, drive a needle into each end of a broom handle; then, having procured two goblets, place each one near the edge of a chair, and from one to the other suspend the broom handle horizontally by means of the needles. If, now, the broom handle be struck a sudden and powerful blow with a stout stick, it will be broken and the goblets will remain intact. The more powerful the blow the more successful will be the experiment. The phenomenon is explained by the resistance of the inertia of the broom handle. The blow being given suddenly, the impulse has not the time to communicate itself from the molecules directly struck, to the neighboring ones, and the first molecules separate from each other before the motion can be transmitted to the goblets, which serve as a support.

—Miss Margaret Hicks, who has recently graduated from the course in architecture at Cornell University, is said to be the first woman who has ever adopted architecture as a profession.

Electrical Experiments.

VERY interesting electrical experiments may be performed by means of very simple apparatus. For example, to show electrical attraction and repulsion nothing more is necessary than a few small cuttings of paper and a stick of sealing wax. When the sealing wax is rubbed it becomes electrically excited and will attract the paper, which, however, soon flies off again after being charged from the wax. Another way of illustrating this curious principle is shown in the accompanying engraving. Take any heavy block for a foot (an old paper file answers well) and fasten on it a wire curved and hooked as we have shown. To this hook at the upper end of the wire attach a silk thread, and to the end of the thread fasten a ball made of the pith of the elder, the sun flower, or Indian corn. Teachers who wish a large ball, visible at a distance, may use two paper hoops about an inch and a half in diameter, and one inch broad. One of these hoops is passed through the other, so that they cross each other and form a sort of skeleton ball. When a stick of wax which is dry, warm and well rubbed with flannel, is brought near such a ball, the latter will swing towards it like a pendulum.

Instead of a stick of wax, a very good substitute is a short, stout sheet of brown paper rolled into a cylinder or tube. The tube should consist of several folds of paper, so as to be quite stiff, and the edges should be fastened down with sealing wax. Such a tube, if strongly heated and well rubbed with flannel, gives very powerful effects. Indeed, in order to obtain an electrical spark, all we need is a simple sheet of paper. A large sized sheet of thick drawing or good brown paper is taken, strongly heated, and laid on a wooden table. It is then rubbed with the dry hand or a piece of flannel until it

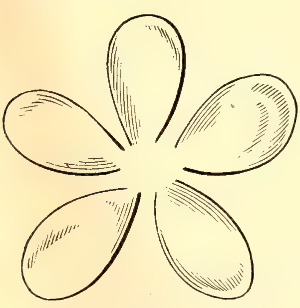


AN ELECTRICAL EXPERIMENT.

adheres to the table. A bunch of keys is now laid in the middle of the paper, and the latter is raised up by two of its corners. If at this moment some one presents his knuckle o the bunch of keys he will draw from it a brilliant spark. If the weather be very dry, and if the paper has been well heated several times, the spark may attain a length of over half an inch. A spark may also be obtained by rubbing a glass tube with a piece of silk and approaching the knuckles to it. The human body may also be electrically charged, so as to yield a spark, by rapid sliding over a carpet, and gas may be lighted by the spark so produced. But in order to show energetic effects, the charge must be accumulated and concentrated. This is best done by means of the Leyden jar, and in our next article we will tell our readers how to make a very simple apparatus of this kind.

Imitation Flowers Made with Liquid Films.

A PRETTY experiment has been recently described by the well-known Belgian physicist, M. Plateau. He bends fine iron wire as in the figure, so as to present the contour of a flower of any number of petals. The central ring to which the petals are attached is supported on a forking stem, which is stuck in a piece of wood. After oxidizing the wire slightly



FRAME FOR LIQUID FILMS.

with weak nitric acid, the flower is dipped in glycerine liquid, so as to receive films in the petals and the central part. It is then turned up, placed on a table near a window, and covered with a bell jar. For a short time at first it appears colorless, but soon a striking play of colors commences. In the experiment described by M. Plateau, the flower continued showing modifications of color for ten hours, when dusk stopped observation. Next morning several petals had burst, the liquid used having been of very inferior quality. M. Plateau recommends preparation of the liquid thus: Dissolve a fresh piece of Marseilles soap, cut up into small pieces, in forty parts by weight of hot distilled water. Filter after cooling, and mix thoroughly three volumes of the solution with two of Price's or any other pure and heavy glycerine. The solution should be left at rest till all air bubbles are gone.

Blue Process of Copying Drawings.

THIS process is so simple and involves so little trouble that it has been almost universally adopted by engineers and mechanical draughtsmen. The following are the details as given by Mr. P. Barnes, of Springfield, Ill., before the American Institute of Mining Engineers:

1. Provide a flat board as large as the tracing which is to be copied.

2. Lay on this board two or three thicknesses of common blanket, or its equivalent, to give a slightly yielding backing for the paper.

3. Lay on the blanket the prepared paper, with the sensitive side uppermost.

4. Lay on this paper the tracing, smoothing it out as perfectly as possible, so as to insure a perfect contact with the paper.

5. Lay on the tracing a plate of clear glass, which should be heavy enough to press the tracing close down upon the paper. Ordinary plate glass of three-eighth inch thickness is quite sufficient.

6. Expose the whole to a clear sunlight, by pushing it out on a shelf from an ordinary window, or in any other convenient way, for six to ten minutes. If a clear skylight only can be had, the exposure must be continued for thirty or forty-five minutes, and under a cloudy sky, sixty to ninety minutes may be needed.

7. Remove the prepared paper and

drench it freely for one or two minutes in clean water, and hang it up by one corner to dry.

Any good hard paper may be employed (from even a leaf from a press copy book up to Bristol board) which will bear the necessary wetting.

For the sensitizing solution take 1⅞ ounces citrate of iron and ammonia, and 8 ounces clean water; and also, 1¾ ounces red prussiate of potash and 8 ounces clean water; dissolve these separately and mix them, keeping the solution in a yellow glass bottle, or carefully protected from the light.

The paper may be very conveniently coated with a sponge of 4 inches diameter, with one flat side. The paper may be gone over once with the sponge quite moist with the solution, and a second time with the sponge squeezed very dry. The sheet should then be laid away to dry in a dark place, as in a drawer, and must be shielded from the light until it is to be used. When dry, the paper is of a full yellow or bronze color; after the exposure to the light, the surface becomes a darker bronze, and the lines of the tracing appear as still darker on the surface. Upon washing the paper, the characteristic blue tint appears, with the lines of tracing in vivid contrast.

It will readily be seen that the process is strictly photographic in the ordinary sense of the word—the tracing taking the place in the printing of the ordinary glass negative. Hence, all details are closely reproduced, even to the texture or threads of the tracing cloth.

A working drawing thus made furnishes its own background, and does not require to be placed over a white ground, as is often the case with a tracing. If desired, the copy can be made upon common bond paper, which can be mounted upon a board in the usual way.

Inasmuch as such copies can be made from tracings only, it may be well to suggest, and urge, that drawings can be completed, or nearly so, in pencil upon paper in the usual way, and that all the inking can be done upon tracing cloth laid upon the pencil-work. In this way the cost of the tracing (in the ordinary sense) can be wholly saved, and the single copy of the finished tracing can thus be made in the "blue" way, to the best possible advantage.

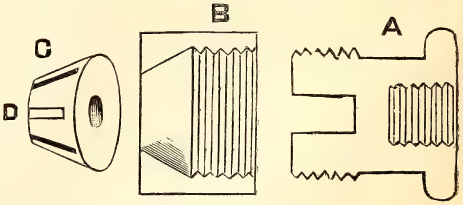
It may safely be said that this method of copying can be employed, if only one or two copies per week are needed of ordinarily complex drawings, with excellent results, and with a very important saving of both time and money.

A ready means of adding to or correcting the blue copies may be found in the use of a solution of carbonate of soda or potash, used with a pen or brush.

A Home Made Chuck.

A CHUCK for small lathes, made after the following plan, does not cost much for material or time, and will be found very useful:

A is a piece of brass to screw on the mandril. It has an external screw on the outer end to receive the brass cover B. The inside of the outer end of B is conical, and C is a piece of wood turned to fit it. When B has been screwed down tight, a



A SIMPLE CHUCK.

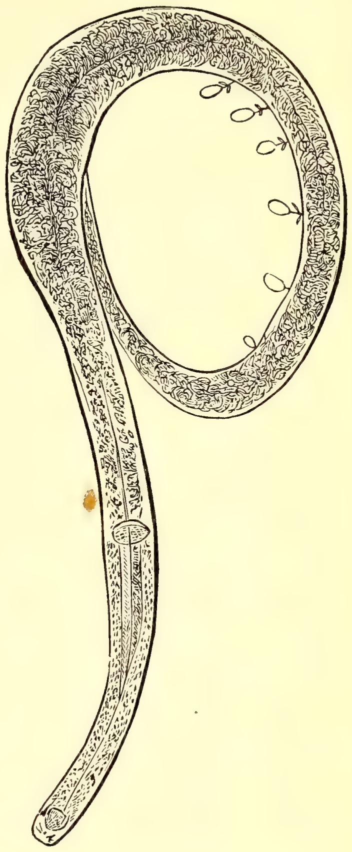
hole the size wanted is turned in C, and a saw cut or two are made as at D. This allows the hole in C to close, and after the article has been inserted, by screwing B on A, it may be held tightly. Little blocks like C are easily turned, and a few of them serve for a wide range of sizes.

—A novel Art College for Women has been established near Wimbledon, England, by Miss Bennett, a lady well known for the gratuitous instruction she has been in the habit of giving in art needlework. The course of study is thorough and comprehensive and the fees are moderate. The students will have the opportunity of getting renumerative employment, if needed.

Marvels of Pond Life—V.

ALTHOUGH the polyps are remarkable for the simplicity of their organization, they do not the less exhib' the wonderful nature of animal life. Their bodies are composed of the substance, called *sarcode*, in which is imbedded a coloring matter resembling that in the leaves of plants; every part possesses irritability and contractility, and they are very sensitive to the stimulus of light. The outer layer of their bodies is harder than the inner layer. These layers are severally called *ectoderm* and *endoderm*. They may be cut and grafted like trees, and if turned inside out, the new inside dig ests and assimilates as well as the old. Whether any form of consciousness can belong to creatures which have no distin ct nervous system is open to doubt, but it would seem probable from their movements that food and light afford them something like a pleasurable sensation in a very humble degree. If we were sufficiently acquainted with the secrets of molecular combination we might discover that the various functions of these simple organis ms were discharged by different *particles*, although it is only in higher creatures that muscular particles are aggregated into muscles, or nerve particles into nerves.

Having examined the general appearance and proceedings of the hydra, let us cut off a tentacle, or take a small specimen and gently crush it by pressing down the cover of the live box, and place the object so prepared under a power of about three hundred linear. If we then illuminate it with a moderate quantity of oblique light, we shall discover round the edge of the tentacle a number of small cells or capsules, from some of which a very slender wire or thread will be emitted.* These are the stinging organs of the polyp, and resemble those which Mr. Gosse has so ably elucidated in the sea anemones. Some writers have endeavored to show that they are not stinging organs at all, but so large an amount of evidence to the contrary is accumulated in Mr. Gosse's 'Actinologia Britannica,' that no reasonable doubt remains. The stinging capsules of the polyp are shown in the annexed sketch, and also the way in which they are employed, for it fortunately happened that on exposing one of the hydras to pressure in the live box, a small worm (*Anguillula*) escaped, which had been pierced with the minute weapons which are supposed to convey a poison into the wound. The authors of the 'Micrographic Dictionary' think that the prongs of the forks, which will be seen to point upwards in the sketch,* are springs, and occupy a reversed position in the capsule cells, and that their function is to throw out the threads. However this may



Anguillula pierced by stinging organs of the *Hydra viridis*. × 300.

be, the polyps, and similarly endowed creatures, have the power of darting out their poison threads with considerable force, and Mr. Gosse found that the anemone was able to pierce a thick piece of human skin.

The same excellent observer attributes the emission of the anemone poison threads, which he considers hollow, to the injection of a fluid. In their quiescent state, he thinks they are drawn in, like the finger of a glove, and are forced out as the liquid enters their slender tubes. Possibly the polyp stinging organs may have the same structure.

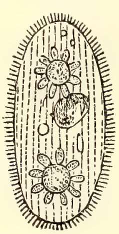
Notwithstanding their dangerous weapons, polyps are often infested with a

* See C and D, page 150, Dec., 1881.

parasite, the *Trichodina pediculus*, (which will be shown further on), and it must happen that either this visitation is not disagreeable, or that the Trichodina is not influenced by the poison.

As the plants in the bottles decayed, some of the animalcules died off and others appeared. In one bottle, containing decaying chara, *Paramecia* abounded. The *Paramecia,* of which there are various species, have always been favorite objects with microscopists. The Germans call them "slipper animalcules," and they vary in size from 1—96″* to 1—1150″. They are flat rounded-oblong creatures, with a distinct integument or skin, "through which numerous vibratile cilia pass in regular rows."† They are furnished with a distinct mouth, and adult specimens exhibit star-shaped contractile vesicles in great perfection.

The swarm of specimens before us belong to one species, *Paramecium aurelia,* the *Chrysalis animalcule,* and they crowd every portion of the little water-drop we have taken up, and examined with a power of about one hundred linear. When they are sufficiently quiet a power of about four hundred may be used with advantage, and Pritchard recommends adding a little indigo and carmine to the water, in order to see the cilia more clearly, or rather to render their action more plain. The cilia are disposed lengthwise, and Ehrenberg



Paramecium aurelia.

A dried specimen showing the vesicles.—*Pritchard.*

counted in some rows sixty or seventy of them, making an aggregate of three thousand six hundred and forty organs of motion in one small animated speck. This number seems large, but although we have never performed the feat of counting them, we should have expected it to prove much greater. Unlike most animalcules they are susceptible of being preserved by drying upon glass, and we subjoin a figure from Pritchard, of one thus treated, in which the star-shaped vesicles are clearly seen. These curious organs communicate with other vessels, and, as we have previously stated, are probably connected with respiration and excretion.

The genus *Paramecium* is now confined to those creatures which exhibit rows of longitudinal cilia of uniform length, which are destitute of hooks, styles, or other organs of motion than the cilia, which have a lateral mouth, and no eye-spots. One mode of increase is by division, which may be easily observed; another is through the formation of true eggs as traced by Balbiani.

Another of the treasures from the pond was a species of *Trachelius*, or long-necked ciliated animalcule, which kept darting in and out of a slimy den, attached to the leaf of a water-plant. The body was stout and fish-shaped, the tail blunt, and the neck furnished with long conspicuous cilia, which enabled the advancing and retreating movements to be made with great rapidity. The motions of this creature exhibit more appearance of purpose and design than is common with animalcules, but in proportion as these observations are prolonged, the student will be impressed with the difficulty of assuming that anything like a reasoning faculty and volition, is proved by movements that bear some resemblance to those of higher animals, whose cerebral capacities are beyond a doubt. It is, however, almost impossible to witness motions which are neither constant nor periodic, without fancying them to be dictated by some sort of intelligence. We must, nevertheless, be cautious, lest we allow ourselves to be deceived by reasoning so seductive, as the vital operations of the lowest organisms may be merely illustrations of blind obedience to stimuli, in which category we must reckon food, and until we arrive at forms of being which clearly possess a ganglionic system, we have no certainty that a real will exists, even of the simplest kind; and perhaps we must go still higher before we ought to believe in its presence.

Ehrenberg was much struck with the restless character of many infusoria—whether he looked at them by day or by night, they were never still. In fact their motions are like the involuntary actions which take place in the human frame; and if attached to their bodies we observe cilia that never sleep, the living membrane of some of our own organs, the nose, for example, is similarly ciliated, and keeps up a perpetual though unconscious work.

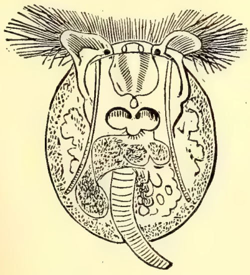
The *Paramecia* increase and multiply their kind without any fear lest the due adjustment between population and food should fail to be preserved. A small drop of the scum from the surface of the water in their bottle is an astounding sight. They move hither and thither in countless numbers, seldom jostling, although thick

* The usual mode of giving dimensions is by fractions thus expressed: 1—96″ means one ninety-sixth of an inch.

† 'Micrographic Dictionary.'

as herrings in a tub, and in many portions of the field the process of self-fissure, or multiplication by division, is going on without any symptoms of discomfort on the part of the parent creature. This is an interesting sight, but we will not linger over it, for the sun is shining, and there is enough warmth in the air to make it probable that the ponds will be more prolific than in the cold winter months. Sunshine is a great thing for the microscopic hunter; it brings swarms of creatures to the surface, and the Rotifers are especially fond of its genial beams. Even if we imitate it by a bright lamp, we shall attract crowds of live dancing specks to the illuminated side of a bottle, and may thus easily effect their capture by the dipping-tube.

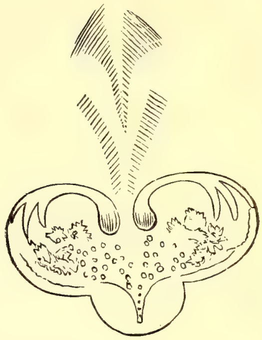
This year the March sunshine was not lost, for on the third of that month I obtained a bottleful of conferva from a pond about a mile from my house, and lying at the foot of the Highgate hills. Water-fleas were immediately discovered in abundance, together with some minute worms, and a ferocious-looking larva



Pterodina patina.

covered with scales; but what attracted most attention was a Rotifer, like a transparent animated soup-plate, from near the middle of which depended a tail, which swayed from side to side, as the creature swam along. The head exhibited two little red eyes; two tufts of cilia rowed the living disk through the water, and the gizzard worked with a rapid snapping motion, that left no doubt the ciliary whirlpools had brought home no slender stores of invisible food. Sometimes the end of the tail acted as a sucker, and fixed the animal tightly to the glass, when the wheels were protruded, and the body swayed to and fro. Then the sucker action ceased, and as the creature swam away, a tuft of cilia was thrust out from the extremity of the tail. A power of one hundred linear was sufficient to enable the general nature of this beautiful object to be observed, but to bring out the details, much greater amplification was required, and this would be useless if the little fidget could not be kept still.

The size of the creature, whose name we may as well mention was *Pterodina patina*, rendered this practicable, but required some care. The longest diameter of the body, which was not quite round, was about 1—120″, so that it was visible to



Pterodina patina—gizzard.

the naked eye, and as a good many were swimming together, one could be captured without much difficulty, and transferred with a very small drop of water to the live-box. Then the cover had to be put on so as to squeeze the animal just enough to keep it still without doing it any damage, or completely stopping its motions. This was a troublesome task, and often a little overpressure prevented its success.

Some observers always use in these cases an instrument called a *compressorium*, by which the amount of pressure is regulated by a lever or a fine screw; but whether the student possess one or not, he should learn to accomplish the same result by dexterously manipulating a well-made live-box. We will suppose the *Pterodina* successfully caged, and a power of about one hundred and fifty linear brought to bear upon her, for our specimen is of the "female persuasion." This will suffice to demonstrate the disposition and relation of the several parts, after which one of from four hundred to five hundred linear may be used with great advantage, though in this case the illumination must be carefully adjusted, and its intensity and obliquity frequently changed, until the best effect is obtained.

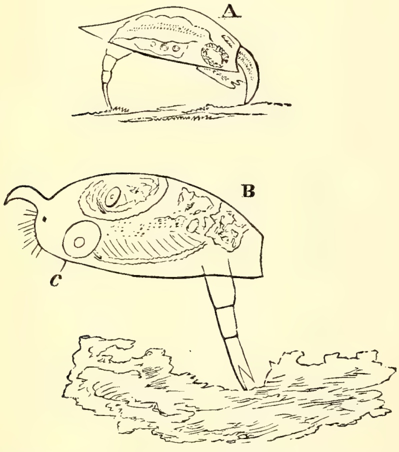
We find, on thus viewing the Pterodina, that it is a complex highly-organized creature, having its body protected by a *carapace*, like the shell of a tortoise, but as flexible as a sheet of white gelatine paper, which it resembles in appearance. Round the margin of this carapace are a number of little bosses or dots, which vary

in different individuals. The cilia are not disposed, as at first appeared, in two separate and distinct disks, but are continuous, as in the annexed sketch. Down each side are two long muscular bands,

Pterodina patina—tail foot.

distinctly *striated*, and when they contract, the ciliary apparatus is drawn in. As this contraction takes place, two apparently elastic bands, to which the ciliary lobes are attached, are bent downwards, till they look like the C springs behind a gentleman's carriage; and they regain their former position of slight curvature, when the cilia are again thrust out.

The gizzard is three-lobed, and curiously grasped by forked expansions of the handles of the hammers. The tail, or



A. Metopidia accuminata, as drawn by Mr. Gosse. B. Specimen as seen and described in text. *c.* Mouth or gizzard.

tail-foot, can be withdrawn or thrust out at the will of the creature; and when in a good position for observation, a slight additional pressure will keep it so for examination. Delicate muscular longitudinal bands, forked towards the end of their course, supply the means of performing some of its motions, and one, or perhaps two, spiral threads extend through the upper half of its length, and either act as muscles, or as elastic springs for its extension. The intestines and other viscera are clearly exhibited, and a strong ciliary action conducts the food to the gizzard-mouth.

To return to the tail. One spiral fibre is easily discovered; but I have often, and at an interval of months, seen the appearance of two, and am in some doubt whether this was a deception, arising from the compression employed, or was a genuine indication.

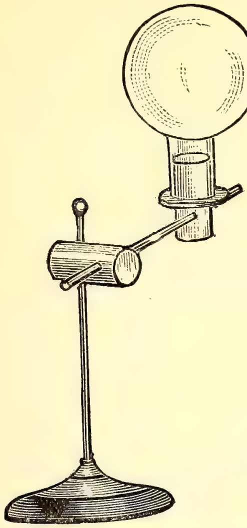
Where this Rotifer occurs I have usually found it plentiful, but unfortunately could obtain no constant supplies after I had determined to make a special study of the remarkable tail, which is much more complicated than I have described. The *Pterodina* lived for some time in captivity, and for a week or two I could obtain them from my glass tank. They were likewise to be found for some weeks in the same part of the pond, but not all over it, until one day not a single specimen could be discovered, notwithstanding a persevering search, nor was I afterwards able to get any from that pond during the remainder of the year.

Makeshifts for Young Microscopists.

IN the earlier numbers of the YOUNG SCIENTIST several simple pieces of microscopical apparatus were described, amongst others a very simple and effective substitute for the stage forceps, and a cheap bull's-eye condenser. I have lately made for myself several pieces of accessory apparatus, from which I get very good results, and it has occurred to me that it might be well to describe them for the benefit of my fellow readers. Amongst other pieces I have made a dark-ground illuminator which works very well, although it cost me actually nothing, except a little work, and a polariscope which cost me $2.50, and by which I get as beautiful effects as those produced by some of my friends who have paid $15 and $25 for their polariscopes. Of course in these estimates of cost I do not count my own time and labor, for I regard the making of these things as so much pleasant recreation.

One of the most useful accessories to the microscope is the bull's-eye condenser, as it is called. This consists of a lens of short focus and large diameter, which is used after the manner of a burning lens; that is to say, it is used to throw a bright

spot of light upon any opaque object that we wish to look at under the microscope. With the cheaper forms of the microscope



HOME-MADE CONDENSING LENS.

an opaque object which is illuminated only by ordinary daylight or lamplight, is hardly visible, but if we throw a beam of light on it by means of a condenser, it at once becomes visible, and such objects as seeds, shells, butterfly's scales, etc., seen in this way, are not only interesting, but really very beautiful. A short time ago, being on a visit to a friend's house, I found a young boy working with a cheap microscope, and trying to examine some portulacca seeds, which he had heard were very beautiful. Unfortunately, however, their beauties remained hidden, because they were literally kept in the dark. Rummaging amongst some odds and ends I found a small flask about an inch and a half in diameter. This I filled with glycerine, and then taking two corks and a darning needle I arranged the whole on an old paper file, as shown in the engarving. This little contrivance gave splendid results, and enabled me to bring out the beauties of quite a number of opaque objects, such as seeds, scales, feathers, etc.

In filling such a globe, I always use glycerine where I can get it. I do so because glycerine makes a stronger condenser, and also because in cold weather it does not freeze and burst the flask. O. W.

Cutting, Grinding and Engraving Glass—I.

TO ordinary persons, glass is a synonym for brittleness, and very few people ever think of it as an article that can be cut and worked like other materials. But those who have had a little experience find that glass is very easily shaped and finished, and as it is susceptible of taking a very high polish, its transparency and refractive powers give it a peculiar beauty which specially adapts it to the finer kinds of ornamental work. In former numbers we have told our readers how to cut it with a diamond or hot iron, and how to bore it with a steel drill, with emery, and with a diamond. We now propose to point out one or two other methods by which it may be worked up by the amateur for special purposes.

As a lid for an ornamental box, or a panel for a fancy cabinet, glass has peculiar fitness. In some cases it is bes when left perfectly transparent, so as to show the contents, as for example, where boxes are used for holding specimens of natural history. In this case good ordinary window glass may be used, and it is easy to cut the glass to fit the lid of the box and then fasten it in, after cutting out the material which it is to replace. A stout paste-board box with a plate of glass for a top, is exceedingly useful and convenient. But where the box is intended for ornament as well as for use, as for example, glove boxes and collar boxes, work boxes, etc., the glass may be beautifully ornamented by engraving it by means of the sand-blast, as will be explained in a succeeding article. Those who have had no experience in such work will be astonished how easily the most beautiful figures may be worked on glass by the sand-blast process, and the apparatus required is of the simplest kind, such as may be made by any one. Where glass panels are fitted to the doors of cabinets, such for example, as those used for holding microscopic objects, it is best to use heavy plate glass and

to bevel the edges. This is easily done if the proper tools are at hand. At first sight one would think that a good grindstone would be the best tool for grinding down the bevels of such a panel, but we have never found one that would answer even tolerably. Working glass on a grindstone is tedious, disagreeable work, and those who give much attention to glass-grinding will find it to their advantage to provide a suitable plate of cast iron or other metal. The plate should be round, and it should be mounted like a potter's wheel. In other words it should be fixed to the top of an upright spindle so that it may revolve horizontally, the glass being held against its upper surface. For such a purpose a cast iron plate is best and cheapest. It should be turned perfectly true, and the "skin" or hard outer scale of the casting should be entirely removed. When such a plate is fed with good sharp sand or emery, and is made to revolve rapidly, it cuts glass very fast. It takes but a few minutes to grind off the edge of a common tumbler so that it will be quite true, after which it may be used as a receiver for an air-pump. We have several glass vessels which were ground in this way, and which have proved very serviceable in experiments on gases, as they may be closed air-tight by means of a piece of plate glass and a little lard.

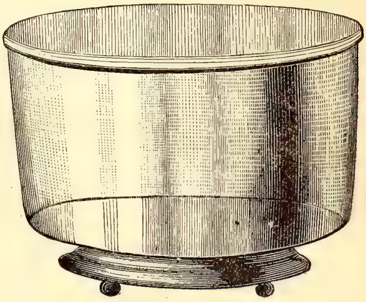
It is equally easy to grind off the edge of a thick glass plate so as to form a bevel on it, and since the great beauty of such a plate consists in its high polish and freedom from scratches, special care ought to be taken to prevent the sand or emery from acting upon the polished parts. This is best effected by pasting a piece of tough paper over the entire surface to be protected.

The grinding material consists of sand or emery and water, of which several grades of fineness should be provided. And as the muddy mixture flies off the plate as soon as the latter is set in motion, a hoop of paste-board, tin or zinc should be placed round the wheel or plate to catch it. The great objection to the operation is the dirt that it makes, but this is easily remedied by the use of an old apron or even a few newspapers, and any spots that may get on our clothes are easily brushed off when dry.

(To be continued.)

Taming Fishes.

PROCURE a large bell-glass—twenty inches in diameter—if you can get it. Such bell-glasses usually have a knob which prevents them from standing mouth up. Provide a block of wood with a large hole in it, or better still a stand like that shown in the figure; set it on a stand in a north window; lay down a bed of pebbles; plant a few tufts of water-weed (*Anacharis*), and fill with river water. After it has stood a few days, procure three small Prussian carp and six minnows. Have no gold-fish, no molluscs, and no rockwork. Allow the conferva to grow on the glass, except on the side next the room, which keep clean.



BELL-GLASS FOR AQUARIUM.

Every morning and evening feed the fishes with very small earthworms, gentles, or small caterpillars, and be careful to drop them in only one or two at a time, so that none be left to foul the water. Frequently sit beside the vessel, and watch the gambols of your pets; now and then tap on the front of the glass with your finger-nail, and so accustom them to your presence. By degrees they will get bold and playful; be sure to tap with your finger-nail before you feed them, and instead of dropping the food in for them to take it in their own way, hold a worm between your fingers at the surface, and one of the boldest of the minnows will snatch it away playfully. Persevere, and you may call them together by tapping on the glass, and have them feed from your fingers, and even submit to be tickled on the back in quiet enjoyment of your friendship and familiarity. H.

THE

Young Scientist.

A Practical Journal for Amateurs.

With which has been incorporated
"THE INDUSTRIAL MONTHLY,"
"THE TECHNOLOGIST," AND
"HOME ARTS."

PUBLISHED MONTHLY AT 50*cts. PER YEAR.*

Postage free to all parts of the United States and Canada, except when delivered by letter carrier in New York City, in which case 12 cents per year postage is charged.

For Club Rates and Premium List see Prospectus.

Advertisements 30 cents per line, agate measure.

All communications should be addressed to

THE YOUNG SCIENTIST,
14 Dey Street, New York.

REMITTANCES.—Make all checks and postal orders payable to John Phin. U. S and English postage stamps received at full value for sums less than One Dollar. Canadian postage stamps are of no use to us, but Canadian silver and fractional currency will be received at full value.

Important Notice.

THIS number of the YOUNG SCIENTIST is sent as a sample to all our old subscsibers and to many who have never taken the journal. It is unnecessary for us to intimate that we would be glad to have all who see this number send us their subscriptions, but it may be well to say that no bills are sent out for the YOUNG SCIENTIST, and no credits given. When a subscription expires the journal is stopped. Our reason for this course lies in the simple fact that the price of the journal is so low that it is impossible for us to keep book accounts and send bills.

Who Wants a Rifle?

WE have a very fine little Flobert rifle, the bore of which has been rifled so that it shoots with great accuracy. (The ordinary Flobert rifles are all smooth bores.) It is just the thing for small game or target practice, and we will give it to the first that sends us a club of fifty subscribers to the YOUNG SCIENTIST. Remember, this weapon will be given to the first that completes a club of fifty ; after that, those who wish a rifle as a premium, will have to be satisfied with the ordinary weapon.

1882.—To Our Readers.

WITH this number the YOUNG SCIENTIST enters upon its fifth year. In noting the addition of another volume to the series, we cannot help acknowledging the appreciation which our efforts have received, and assuring our readers that their kind words and efforts have not passed unheeded by us. We could each month fill one or two pages with extracts from commendation letters that we have received, but we have always preferred to occupy our limited space with matter of more immediate value to our subscribers.

Our arrangements for 1882 are such that we feel assured that the fifth volume will be better than any that has preceded it. Prof. Wright will give us each month a series of interesting notes on astronomy. Mr. Hodgson will continue his thoroughly practical articles ; the "Marvels of Pond Life" will, as the summer advances, increase in interest and in the wonders which they develop; and we have engaged a series on the aquarium, the lathe, glass working, the voltaic battery, scientific experiments, etc. We hope also to be able to give the best series of articles on boat-building that has ever appeared. There are other interesting and important subjects in regard to which we have corresponded with writers who are able to give us good and popular articles. Amongst these is a monthly *resume* of the scientific progress of the world. Such a series might, we think, give our young people, and even some of our older ones, a valuable hint, at least of all the most important discoveries.

How far we shall be able to make the YOUNG SCIENTIST for 1882 equal to what we would like it to be, remains to be seen. We shall faithfully do our best, and we hope to receive aid from every one who has enjoyed reading our paper.

And now, reader, let us suggest a method by which you can aid us materially in the improvement of *your* journal and ours. It is simply by calling the attention of all your friends to the YOUNG SCIENTIST. If any of your numbers are injured by so lending or showing them, we will cheerfully replace them, and if

you can secure any subscriptions, our premium list affords a great variety of opportunities for procuring something that you want. The great obstacle in the way of the success of a small paper of the special character of the YOUNG SCIENTIST is the expense of advertising. Therefore, we must rely largely upon the kind offices of our readers to make the journal known to others. So much, then, for hopes and expectations for the coming year. In the hope that it will be a successful one for us and a pleasant one for you, we wish you

A MERRY CHRISTMAS AND A HAPPY NEW YEAR.

Bound Volumes for 1881.

WE have made special arrangements for binding the YOUNG SCIENTIST in a strong, neat and cheap manner. After the 20th of this month we will be able to supply bound volumes for 1881 for $1.00 each, or to bind the numbers of our subscribers for 35 cents each. This sum does not include postage where the volumes are sent by mail. Mailing costs 15 cents extra

BOOK NOTICES.

Lectures in a Workshop: By T. P. Pemberton, formerly Associate Editor of the "Technologist;" Author of "The Student's Illustrated Guide to Practical Draughting." With an appendix containing the famous papers by Whitworth "On Plane Metallic Surfaces or True Planes;" "On an Uniform System of Screw Threads;" "Address to the Institution of Mechanical Engineer's, Glasgow;" "On Standard Decimal Measures of Length." $1.00. New York: Industrial Publication Co.

The volume before us consists of a series of lectures and articles specially addressed to young mechanics. Several of these lectures were delivered before the Polytechnic Association of the American Institute, and were received with very great favor. The whole has been carefully revised and the unavoidable repetitions of an unconnected series having been cut out and other and more valuable points enlarged. The collection now torms a sprightly, fascinating book, full of valuable hints, interesting anecdotes and sharp sayings. It is not a compilation of dull sermons or dry mathematics, but a live, readable book. The papers by Whitworth, now first made accessible to the American reader, form the basis of our modern systems of accurate work.

The Boston Journal of Chemistry and Popular Science Review: Devoted to Chemistry, Pharmacy, Geology, Agriculture, Astronomy, Hygiene, Medicine, Practical Arts, Home Science, etc., etc. $1.00 per year. Boston: Journal of Chemistry Company,

This valuable journal has come to our desk regularly during the past year, and is always read with interest. It has recently enlarged somewhat the range of subjects which it discusses, and is now one of the very best exponents of general scientific progress. It gives brief notes of almost all scientific discoveries, and the care with which it is edited and the low price of its subscription commends it to those who wish to keep posted, but whose time for scientific study is limited.

The Builder and Wood Worker: A Journal of Industrial Arts. Published Monthly at 176 Broadway, New York. Chas. D, Lakey, Publisher. Fred. T. Hodgson, Editor.

The December number completes the seventeenth volume of this sterling periodical, which, under the able editorship of Mr. Hodgson, has now reached a circulation of which even sensational journals might be proud. The numbers which have reached us regularly during the year have been characterized by sound good sense, thorough knowledge of the arts which they discuss, and perfect ability to make matters clear to even the dullest workman. The illustrations, of which there is every month several full pages of detail drawings, are alone worth far more than the small price—$1.50—asked for the journal. Those who desire to club the *Builder and Wood Worker* with the YOUNG SCIENTIST can have both journals for $1.50.

Correspondence.

Protect the Birds.

Ed. Young Scientist—Now that the winter has arrived and the ground will soon be covered with snow, it would be a good idea for the readers of the YOUNG SCIENTIST and their friends, both boys and girls, to scatter food to the poor little birds, who are unable to obtain food for themselves; and I am sure any boy or girl who follows the above suggestion will be amply repaid at the end of winter to think that they may have saved the lives of the little birds, who will then reward them by their lively song. But while talking about protecting the birds, I would like to suggest that for the coming year (1882) a society should be formed called "The Society for the Protection of Birds." If this suggestion meets with the favor of the editor, I should like to hear from the boys and girls themselves through these columns.

ALEXANDER G. GIBBS.

Astronomy for Amateurs.

BY BERLIN H. WRIGHT.

(All calculations are for the Latitude of New York City.)

THE PLANETS FOR FEBRUARY, 1882.

MERCURY.

This planet arrives at eastern elongation on the 6th, and will be brightest from the 3d to 6th, being 18° 13′ from the sun. As he is east of the sun, he is, of course, an evening star and must be looked for after sunset and in the west. Being north of the sun, his altitude at sunset or at close of evening twilight will be such as to render him an easy object to pick up. On the 1st he sets at 6h. 39m. eve., 5° north of the sunset point; 5th, 6h. 52m. eve., and 7° north, and on the 10th at 6h. 55m. eve., and 8° north of the sunset point. The ⅄ which marks the northern limit of the constellation Aquarius, and through the centre of which the equator of the heavens passes, may be seen about 8° north of Mercury on the 5th. Venus is between Mercury and the sun, but so close to the latter that it is doubtful whether she can be seen at all, and there will be no body in the vicinity of Mercury for which he could be mistaken. The eye is at once attracted by the fiery red planet, so strikingly different from any other heavenly body.

VENUS.

Venus becomes an evening star on the 20th, when she is at superior conjunction. Some little time before that date she may be seen in the east just before sunrise, and afterwards in the west, after sunset. This sudden disappearance of Venus from the horizon and almost immediate reappearance on the opposite side of the earth, apparently 180° from where seen a few days since, was a great puzzle to the ancient astronomers.

MARS.

At 9 o'clock in the evening of the 1st, Mars passes the meridian, being situated in the Milky Way, and in the most interesting portion of the heavens. Betelguese is 20° south of him, and the 2d mag. star *Beta* Aurigae (7° E. of Capella) the same distance north; the Twins, with Castor and Pollux, upon the left; Procyon, Sirius, The "Kings" or "Stars of Orion's Belt," and Rigel, below or south of him; and Taurus, the Pleiades and Hyades, and *Beta* Tauri upon the right. He will be 5° north of the Moon on the 20th.

JUPITER.

Jupiter still remains the most attractive object in the evening sky. Though he and Saturn have the same apparent motion at present, it may be seen that the distance between them is gradually decreasing, owing to the greater motion in right Ascension of Jupiter. He sets as follows: 5th, 0h. 58m. morn.; 15th, 0h. 24m. morn.; 28th, 11h. 38m. eve., arrives at eastern quadrature (90° E. of Sun) on the 6th, and the Moon passes 2° south of him on the 23d.

FAVORABLE TIMES FOR OBSERVING THE PHENOMENA OF JUPITER'S SATELLITES.

(For an inverting telescope at 9h. 12m. eve., New York City Time.)

On the 9th all will be upon the east side of the planet, and very close together. This occurs again on the 16th, when they will be very much closer. On the 6th all that are visible will be upon the west side, but widely separated, II. being in transit, emerging one hour later; this occurs again on the 22d, except that I. and III. are close to each other, and the planet and II. are invisible, being in an eclipse.

The following are the visible eclipses which occur at seasonable hours:

	D.	H.	M.		
III.—	1	8	25	even.	Disappearance.
III.—	1	10	3	"	Reappearance.
I.—	7	6	19	"	"
II.—	8	7	10	"	"
I.—	14	8	15	"	"
II.—	15	9	46	"	"
I.—	21	10	11	"	"

SATURN.

The conspicuous reddish planet about 11° west of Jupiter is Saturn. His rings are in fair position to be seen, and the elevation of the earth above their plane will continue to increase until the latter part of August. The two largest of Saturn's satellites, Titan and Japetus, are easily seen with a telescope of 2-inch aperture, and these with the three next most conspicuous, Rhea, Dione, and Tethys, we have repeatedly seen with an instrument of 3-inch aperture. The following data will enable one to know where to look for these and to identify each, an inverting telescope being supposed to be used: Titan will be at western elongation on the 7th and 23d, and at eastern elongation on the 15th. Rhea, the next in order, is at eastern elongation on the 2d, 6th, 11th, 15th, 20th, and 24th. On the 15th this satellite will be in a line with Titan, and the planet. Dione is at E. elong. as follows: Feb. 1, 4, 7, 9, 12, 15, 17, 20, and 23. Tethys' eastern elongations are as follows: Feb. 2, 4, 6, 8, 10, 12, 14, 15, 17, 19, 21, 23, 25, and 26. Japetus will be at western elongation on the 20th. From the above data we find that on the 20th, for instance, Japetus will be far to the west of Saturn; Titan will be five days from E. elong., and hence about half way to its W. elong. and just north of the planet; Rhea will be at E. elong., and hence upon the opposite side from Japetus; Dione will be on same side

as Rhea and near it, and Tethys will be half way to its W. elong., and hence just north of Saturn and on a line between Titan and the planet.

APPEARANCE OF THE HEAVENS AT 9 P.M. FEBRUARY 15, 1882.

There is no season of the year when there is so grand a display of bright stars, interesting groups and constellations as at this time. Looking southward the eye beholds the richest portion of the heavens spread out before us, dazzling us for the moment by the great profusion of beautiful objects. No less than 30 first and second magnitude stars are in sight, presenting the finest spectacle the starry firmament affords.

Near the meridian and very near the southern horizon are the two bright stars Naos and Phaet, which form the southern termini of the legs of the "Great Egyptian X," which has Sirius for its centre and Procyon and Betelguese for the northern termini. The centre of the constellation Gemini is on the meridian, and the brightest stars, Castor and Pollux, are slightly east. Leo, the Lion, is the next conspicuous constellation eastward, the Sickle and Regulus marking the eastern boundary of Cancer. Virgo is just rising. West of the meridian the Hare, with the neat four-sided figure, is seen 20° south of the "Ell and Yard" or "The Kings," the three bright stars in the belt of Orion; Rigel is between them, but slightly to the right. Opposite the Kings from Rigel and nearly the same distance from them is Betelguese; 25° further north is *Beta* Aurigae, the 2d mag. star in the end of the horn of the Bull, and still about the same distance further north is Capella, 30° west of which is the "Segment of Perseus." Much nearer the western horizon are the Hyades and Pleiades.

THE COMETS OF 1881.

The astronomical discoveries of the year now drawing to a close have been mainly confined to that interesting and erratic class of heavenly bodies called comets. Seven of these visitors from afar off in space have, in their wanderings through the immensities of the stellar regions, passed through our system, and been telescopically visible over nearly the entire globe. Six of them are believed to be new comets, never before having visited us, or at least since scientific observations and records of such events have been made. Only two have been visible to the naked eye, and all of them have been discovered since May 1. At the time of the appearance of Comet 5, Encke's, five comets were telescopically visible—a very unusual, if not unparalleled event. In Feb., 1845, four were visible at once. Mentioned in the order of their discovery they are:

COMET 1 (A).—Discovered by Director Swift at Rochester, Warner Observatory, May 1; small and telescopic.

COMET 2 (B).—The Great Comet. The honor of first discovery in this country has, we believe, never yet been satisfactorily settled. Several hundreds have laid claim to such honor and to the Warner prize of $200. Probably first seen in the United States, June 23. This is without doubt the same comet that Dr. Gould observed at the National Observatory of the Argentine Republic, Cordova, June 1, and he suspected that it was the return of the comet of 1807. But although there were many points of coincidence in the elements of their orbits, later investigation showed very conclusively that they were distinct, and that Comet B had never before been with us. Quite satisfactory spectroscopic and photographic results were obtained from this comet by Dr. Draper and others, demonstrating, among other things, the material nature of the tails of comets.

COMET 3 (C).—Discovered by J. M. Schaeberle at Ann Arbor, Mich., July 13. First seen in the constellation Aurigae. Quite dim.

COMET 4 (D).—Discovered by E. E. Barnard, Nashville, Tenn., in the constellation Virgo, Sept. 19; telescopic.

COMET 5 (Encke's).—Director Swift, of Rochester, was the first to "pick up" this old acquaintance. It has the shortest period of any known comet; 3⅓ years; large telescopic.

COMET 6 (E).—Discovered simultaneously in Europe and America by Mr. Denning, of Bristol, Eng., and Mr. Brooks, of Phelps, N. Y. First seen in Leo, 3½° from Regulus. This is the only short-term periodical discovered this year, its period being 8⅓ years.

COMET 7 (F).—Discovered by Director Swift, of Warner Observatory, Rochester, N. Y., November 17. New and telescopic.

We would not be surprised if one or more cometary discoveries are announced before the close of the year. Eight were seen in 1858, the largest number in this country during a single year, we believe.

EPHEMERIDES OF THE PRINCIPAL STARS AND CLUSTERS, FEB. 20, 1882.

	H.	M.	
Alpha Andromeda (Alpheratz) sets	9	51	even
Omicron Ceti (Mira) variable "	9	59	"
Beta Persei (Algol) variable, in meridian	5	0	"
Eta Tauri (Alcyone or Light of Pleiades) in merid.	5	40	"
Alpha Tauri (Aldebaran) in merid.	6	28	"
Alpha Aurigae (Capella) " "	7	7	"

Alpha Cygni (Deneb) "	0	40	morn
Alpha Pisces Australis (Formalhaut) sets	4	50	even

Penn Yan, N. Y.

Practical Hints.

Ink for Stamping Celluloid.—A recent patent ink for writing or stamping celluloid consists of anilin color dissolved in carbolic acid, with ether or alcohol, or both. Ink so produced will not rub off celluloid goods.

Alcoholic Varnishes.—To make alcoholic lacquers or varnishes adhere more completely to polished metal surfaces 1 part boracic acid should be added to 200 parts of varnish. This composition will adhere so firmly and become so completely glazed as to be removed only with difficulty. Be careful not to add too much of the boracic acid, as it injures the gloss in that case.

Food for Tame Fishes.—Gold fish, minnows and vegetable feeders in general are very fond of boiled rice. They eat it greedily and thrive upon it. The rice is boiled in water until quite soft, then drained nearly dry, and, of course, given when quite cold. The boiled rice grains resemble grubs in appearance, and the fish make for them at once. One great advantage of boiled rice is that is has very little tendency to corrupt the waters. .

Soap Bubble Ballons.—M. Delon, of Paris, produces miniature balloons by means of ordinary gas conducted through a caoutchouc tube and clay pipe to glycerine soap solution. A small disk of thin paper, with fine wire from its centre to a little paper car with æronaut figures, is connected to the bubble when it begins to swell, the disk being attached by capillarity to the part where the drop forms. The detached bubble rises with its car.

How to Make Brass Springs.—Brass cannot be tempered in the manner in which steel is tempered. Hence, the only method to make a brass spring is to compress the metal either by rolls or by hammering. If the springs are to be flat, hammer them out to shape in thickness from soft wire, or sheet brass, somewhat thicker than the finished spring is to be. If the brass shows a tendency to crack in hammering, it must be annealed, which can be done by heating to a light red and plunging into water. In hammering use a light hammer, and don't spare the blows.

Ladies Shoe Dressing.—Extract of logwood, 2 ounces; bichromate of potassa, 2 drachms; yellow prussiate of potassa, 2 drachms; powdered borax, 3 ounces; water of ammonia, 2 ounces; shellac, 16 ounces; water, 1 gallon. Dissolve the extract in water, heating the liquid to nearly the boiling point. Then add the chromate and the prussiate of potassa. After a deep rich blue color has developed, add the borax, and when it has dissolved, the shellac, and lastly, the ammonia. Then keep the whole at a gentle heat, agitating the mixture with stick of wood, until the smell of ammonia has disappeared and the shellac has dissolved.

Hard Putty.—The *Carriage Monthly* gives the following for a hard putty that will dry in one day: Take the whitening, mash all the lumps out on the stone, and mix it into a stiff paste by adding equal parts of japan and rubbing varnish; then add as much keg-lead as you think will make it work free with the knife; then add the rest of the whitening until you have it to suit you. This will sand-paper good with one day's drying. If you want putty that will dry quicker, take dry white lead and mix with equal parts of japan and varnish, to which add a few drops of turpentine. This is very soft for putty, but can be sand-papered in from two to three hours, it becoming perfectly hard in that time.

Improvement in Corks.—Wood-topped corks have long been used, but are not so generally known as they deserve to be. The cork is provided with a cap of wood, which greatly facilitates its removal from a vial or bottle, and forms a very elegant finish. Owing to its breadth, the cap can be grasped in the same way that an ordinary "mushroom opener" is held, and sufficient torsion exerted to dislodge it without the necessity of resorting to a cork-screw. The cap is provided with a central vertical projection, which is glued fast in the centre of the cork, so that the latter must be destroyed before they can be separated. These caps are easily turned by amateurs, and for small cases of chemicals, blow-pipe reagents, etc., they are just the thing. The tops should be turned quite flat, so that a round label may be pasted on the top. This is very convenient when the bottles are kept in a box or drawer.

QUESTIONS AND ANSWERS.

Clay for Modeling.—I have been advised to mix the clay I use for modeling with glycerine, but I find it does not work well. The glycerine all "sweats" out, and besides that, after I get through I want the clay to dry and the glycerine prevents it from doing this. Is there any better remedy? Sculptor.

Ans.—Since water will not evaporate in an atmosphere that is saturated with watery vapor,

you can keep your clay from drying by placing it in a box lined with wet clothes, or you may lay moist clothes on the object, and over this place an oil-skin or rubber cloth. The difficulty is that the weight of the wet cloth is apt to press the object out of shape. Artists found out long ago that the glycerine recipe is a "sell," but our technical papers repeat the directions once a month at least, and our "books of recipes" faithfully copy them.

LIQUID FOR TEMPERING.—The following recipe was taken from ——— ———, a journal in which I have great confidence:—

To give iron a temper for cutting porphyry, make your iron red hot, and plunge it into water distilled from nettles, acanthus, and pilosella, or else in the juice pounded out from these plants. I have written to them for the common names of the plants, but have received no answer. Can you tell me? BLACKSMITH.

Ans.—We regret to be obliged to say that your confidence has been misplaced. The recipe is utterly worthless. As to the name of the plants, with the exception of the first, the author only gives one-half the name. This recipe is a very good sample of the thoughlessness of many of our scientific editors, who do not scrutinize closely the matter which they insert in their columns. The works of the older writers are filled with such trash, and men like Wendell Phillips tell us that if we could only find the proper name of the plant we would recover one of the lost arts.

EXCHANGES.

Only those who are *yearly* subscribers, and whose names are entered on our books have the privilege of inserting exchanges.

Exchanges must be on separate slips of paper or postal cards. If mixed with business letters or cards they cannot be used.

Exchanges must not exceed thirty words.

Buying and selling belong to the advertising department.

We reserve the right to omit the exchange column, when we have not room for it, and the amount of space at our disposal will regulate the number of insertions given to each *exchange*, the preference being always given to those who have not previously used our columns.

To exchange for a wood-turning lathe or offers, a Young America Self-inking Printing Press, with type and outfit complete; chase 3 x 5 inches. Embury McLean, 318 Bloomfield St., Hoboken, N. J.

What offers for "Our First Century," cost $7.00, bound in sheep, over 400 illustrations, 1,000 pages; also small Ruby Magic Lantern, cost $1.50. Box 217, So. Manchester, Conn.

Magic lantern, in good order, condensing lens, 2½ in. diameter, 8 slides. For small photographic camera or offers. H. A. Giddings, 4 Union Place, Classon Ave., Brooklyn.

Printing press, type, etc., worth $13, for offers. E. G. Vogeley, 1010 Bradford St., Pittsburgh, Pa.

Fifty canary birds, with and without crests; fancy poultry, conch shells, strombus alatus. For small printing press, books on natural history, or offers. Frank Lattin, Gaines, N. Y.

A good plain 7 shot revolver, 22 calibre, for a Students' inch or half-inch objective. Frank F. Colwell, Urbana, Ohio.

Wanted, Printing press and type, in good order, chase 6 x 10, or larger; will give hardware, tools, scroll saw, or designs. Chas. E. Little, 59 Fulton St., New York.

Photo outfit, tools, chemicals and apparatus, etc., etc.; wanted scientific books, apparatus, etc.; send lists. A. B. Campbell, Box 59, South Dayton, Catt. Co., N. Y.

Stuffed birds, insects or job printing (cards, labels, etc.) for mounted objects for the microscope. James P. Melzer, Milford, N. H.

A ring stand, filtering stand, calcium light jet and a gas holder, holding one cubic foot, for a phonograph. D. P. Smith, 59 Park Place, New York.

To exchange, Hugh Miller,s "Cruise of the Betsey," and "The Old Red Sandstone," cloth bound geological books, for lathe, hammock, or "Gray's Manual of Botany." Gus. C. Spaeth, Mt. Carmel, Ills.

F. F. F., Lock Box 83, St. Johnsbury, Vermont, would like to exchange or correspond with persons interested in mineralogy, Oology, philatology, Indian relics, books, entomology, numismatology, etc.

Wanted, a good printing press and type; state what is wanted in exchange. H. A. Kinney, Hamlin, Brown Co., Kansas.

I have a printing press and outfit (cost $15) to exchange for books, microscope, tent, watch, or offers. Henry E. Jacobs, 59 Harvard Street, Boston, Mass.

I have Vols. 2 and 3 of "Nests and Eggs of American Birds," to exchange for Vol. I of YOUNG SCIENTIST, or offers. N. B. Stone, Lock Box 9, Putnam, Conn.

Wanted, a printing outfit or offers, in exchange for baritone cornet, air gun, and other things, a list of which will be furnished upon application. E. S. Nixon, Jr., Box 345, Chattanooga, Tenn.

To exchange, minerals, ores, shells, papers, magazines, books, coins, stamps, for stamps, coins, minerals, stylographic pen, telephone, etc. A. M. Beveridge, P. O. Box 854, Appleton, Wis.

Will exchange minerals for other minerals; state what specimens you desire. E. A. Refsnyder, Phœnixville, Chester Co., Pa.

Wanted, a good powerful second-hand microscope; forward engraving of instrument, stating price, or what is wanted in exchange. L. D. Snook, Barrington, Yates Co., N. Y.

Wanted, botanical specimens of Western, West Coast, and Southern ferns, in exchange for Northern species; lists exchanged. H. N. Johnson, Coeymans, N. Y.

Wanted, copy of "Snowball's Elementary Natural Philosophy." M. B Tausy, Harrisburg, Pa.

A new 2 x 4 engine, worth $60, for a first-class bicycle; also a watch, revolver, and gas stove, for a 6 x 9 printing press, type, or offers. Geo. L. Lamson, La Fargeville, N. Y.

To exchange, specimens in botany, oology, etc., for those in other localities; botanical correspondents desired. Arthur Fairbanks, St. Johnsbury, Vt.

A German microscope, with 3 objectives and 5 eye-pieces, condensing lens, etc., resolving Pleurosigma angulatum, will be exchanged for a first-class spectroscope. Clarence L. Speyers, 50 West 17th St., New York.

Shells and Corals.—These beautiful objects form favorite parlor ornaments for the mantel-piece and the what-not, but under such circumstances they are generally looked upon as mere curiosities—" only this and nothing more." Mr. H. T. Woodman has taken a new departure in this direction, and has put up a number of boxes—none of which contain less than one hundred specimens—and which he sells for from 25 to 50 cents each. This gives not only a number of objects of great beauty, but a series of specimens, the examination and comparison of which cannot fail to afford much useful and interesting information. Our young friends who are at all interested in natural history cannot do better than to invest a few cents in one of these boxes. Mr. Woodman may be found at 23 Clinton Place, New York.

The Young Scientist

SCIENCE IS KNOWLEDGE.

KNOWLEDGE IS POWER.

INDUSTRIAL PUBLICATI

A PRACTICAL JOURNAL OF

HOME ARTS.

VOL. V. NEW YORK, FEBRUARY, 1882. No. 2.

Cheap Lathes and How to Use Them.

BALLS and tops have always been favorite toys with boys, and no better exercise can be found for those who wish to begin lathe work than the making of a top for a younger brother or some little friend. It is not likely that the boy who makes the top will want to play with it, and this is so much the greater reason why a top should be chosen for a first effort, since the pleasure to be derived from making it will be trebled by seeing the pleasure it will give to another.

In order to be able to make a good top, the young turner must understand the method of using it and the points which render it good or bad. And this is true of every article made by human skill. He who works merely after a pattern without a thorough knowledge of the end to be attained will never achieve true success.

It is also necessary to take into consideration the character of the person who is to use it. Some little girls are very fond of spinning humming tops, while boys rarely care much for them. The favorite top amongst older boys is the kind known as the *peg top*, which is spun in the following way: A piece of fine whip cord is wound tightly round the conical part of the top which is then thrown to the ground in a manner well known to boys. The uncoiling of the cord causes the top to revolve or spin, and it continues to do so long after it has struck the ground. Part of the game of top-spinning consists in striking other tops so as to drive them out of a ring or even to split them, in which latter case the peg of the split top becomes the trophy of the one who split it. If tops are made too squat, with very short pegs, they are apt to "sleep"—that is to spin quietly and so offer a fair mark to the player who wishes to split them. On the other hand, tops with long pegs never stand still. They

keep constantly moving about and are very difficult to hit.

Tops are made of different varieties of wood, according to the kind of top and the person who is to use it. Thus, if the top is for a very little boy it may be of soft wood (pine or basswood) and shaped like the Spanish top which is shown in Fig. 1. This top is generally made of mahogany; it has not a peg, but instead of that it is furnished with a rounded knob at the lower end and it spins very quietly, consequently it may be used upon wooden floors and smooth pavements. Such a top is one of the easiest things to make, and very neat ones may be turned up in the simplest and cheapest kind of lathe. Peg tops are generally made of one of the harder kinds of wood, such as beech, maple, elm, apple, pear, mahogany, lignum vitæ or boxwood. Boxwood is said to make the best top; we are told that lignum vitæ answers admirably. Beginners, however, will find it difficult to work, and therefore we would recommend elm, pear, apple or dogwood as the best material for a first trial on a peg top.

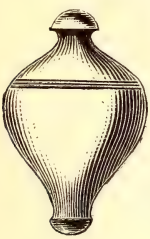

Fig. 1.

The peg should be of steel. Most of those which are sold are mere bits of iron wire. A few of the better class are of steel wire. Choice tops have a special forged steel peg, made conical and with a tang like that shown in Fig. 2.

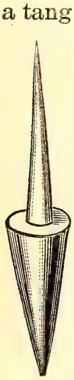

Fig. 2.

When well turned this makes a very fine peg. It cannot be driven into the wood so as to split the top, and the weight makes the top easy to throw. When a forged peg cannot be had, a very good one may be made out of a large bradawl which may be bought for a trifle in any hardware store. Soften it in the fire, cut off the round part to a length of about three-quarters of an inch, and file the square shoulders as round as you can. It is then ready to be driven into the wood. First of all, however, you ought to examine some good top, either in the stores or by borrowing it for a few minutes from the owner. In this way you will get a correct idea of the shape, etc., of the article you wish to make.

Having decided upon size and shape, procure a piece of good tough wood, close grained and well seasoned. Pare off the corners with a chisel or hatchet so as to make it nearly round. The object of this is to leave as little work for the gouge and chisel as possible. In the hands of an experienced turner, and with a good strong lathe, the corners can be ripped off with a gouge as quickly or even more quickly than with a hatchet. It is astonishing what an amount of wood can be cut off in a few seconds in the lathe when one knows how to do it, the great secret of success being a high speed, a sharp tool and a steady hand. For beginners, however, we would advise the removal of the corners by means of an axe or knife. The knife best suited to such purposes is the common draw knife with two handles. The wood is held in a vice or clamp, a circle is marked on each end with a pair of dividers, and the corners are carefully paired off to this circle. Those who have a small plane may use it and make the piece of wood very nearly quite round before putting it in the lathe. The wood is now ready for centering, and as this demands a consideration of the most suitable kind of lathe centre for such work, we will treat this point in our next article.

(To be continued.)

A Hanging Cabinet.

BY FRED. T. HODGSON.

THE proficient scroll-sawyer will no doubt, after a time become tired of making brackets, card-baskets, photo-frames and the thousand and one other useful and ornamental articles that are usually made up of work formed almost entirely by the aid of the scroll-saw. To give him an opportunity of trying his skill on something equally as useful, more durable, and perhaps just as handsome, I propose to show him how he can make a very nice "hanging cabinet."

To begin with, I present at Fig. 1 a

front view drawn to scale, and will try to describe it and give such instructions for its construction, that I think will make it

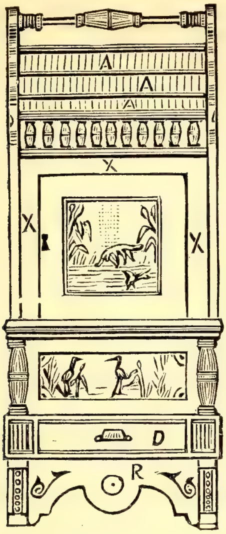

Fig. 1.

possible for any amateur fairly skilled in the use of tools, to make one as complete as the one shown in the engraving.

The actual example from which the engraving is taken is made of cherry ebonized, and is extremely pretty; I would therefore suggest that cherry be used for making the one now under consideration. To this end it will require two pieces for sides, about 9 inches wide, and 2 feet 8 inches long, and 1 inch thick. About three feet superficial measure and 1 inch thick for a panel door, front casings X X X, front of drawer D, and top A A A. The shelf over the drawer, the bottom of the cabinet, the slide under the drawer, and the double bracket R under the drawer may be made of cherry five-eighths, nalf inch, or three-eighths thick. The outsides of the drawer should be made of stuff 2 inches thick, and have small panel on the end of each one as shown on the front view. The door is framed together like any ordinary panel door, and the ornamental panel in the centre is simply a single Minton tile, or where the tiles cannot be obtained a plain pine panel may be substituted, and hand-painted, or plate or stained glass may be used, but when tiles are used a much better effect is produced. The panel in the back, just above the drawer, may be hand-painted or otherwise ornamented.

The double bracket R, and the circular brackets at the lower ends of the sides, may easily be cut out by aid of a scroll saw, so also may the side brackets above the drawer and the ornaments on the top of the sides.

Fig. 2 shows a scale by which all the

Fig. 2.

measurements in the engravings, Figures 1 and 3, may be taken. The small divisions represent inches, and the largest divisions represent feet. It will be seen that by using this scale any part of the design may be measured accurately and transposed to actual inches and feet.

The ornaments shown on R and on the side, Fig. 3, are incised or cut into the

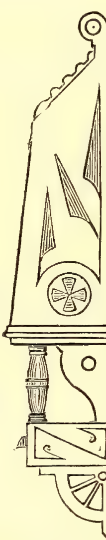

Fig. 3.

wood about a quarter of an inch deep, and the widest incisions, like the Maltese cross and the lance-head ornaments, should be embossed. This can be done with punches, but where these are not avail-

able, a blunt pointed nail will do very fair work. The incised work wants to be done very carefully. And where it consists of narrow channels only, care must be taken to have the groves of parallel width. When done well, this style of work has a good effect. After the cabinet is complete, ebonized and finished up, the incised work might be touched up, or, as finishers say—pricked in with gold. A very few sheets of gold leaf will do this, or where this cannot be done, liquid gold may be applied with a fine brush.

The top rail should be turned out of a piece of cherry 2x2 inches, the exact length between its shoulders must be the same as the distance between the sides of the cabinet. The two small columns between the drawer and the cabinet shelf are turned out of stuff 1½x1½ inches thick, and are fastened at both ends with pins that are left in the ends of columns and go into holes bored into the shelves. The ribbon moulding that runs around the front and the two sides, over the two small columns, is glued and nailed on with small nails where heads must be sunk below the surface of the wood.

The cover A A A is made of stuff 1 inch thick, and is cut to look like shingles. To make this is a very simple matter, as will easily be seen by a close inspection.

The drawer requires the front to be made of cherry, but the sides, end and bottom may be made of pine or any other soft wood. Where it can be done, it is better to dove-tail the drawer, but where this cannot be done, halfing the pieces together will answer the purpose. The pull on the drawer is made of wood, but where brass or nickel plated goods can be obtained it would be better to have a brass or nickel plated drop handle. The door should also be trimmed and hung with brass or nickel plated hardware.

Fig. 3 shows a side view of the cabinet. It will be noticed that the top end is somewhat narrower than the bottom, this necessarily makes the door on an incline which insures its closing after using.

Fig. 4 shows the turned balusters on the top of cabinet in front. It also shows the style of moulding used for rail and base piece of balusters. The dotted lines show the pins on the end of balusters by which they are fastened into the rail and base piece. These are drawn to full size.

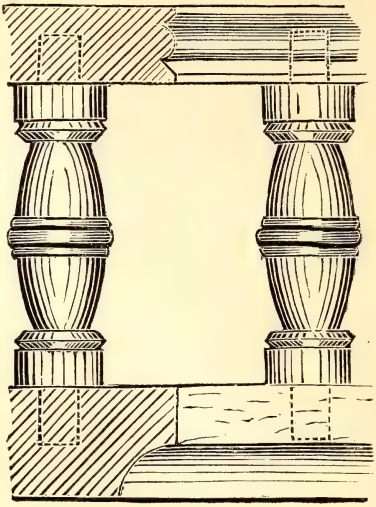

Fig. 4.

Fig. 5 shows a perspective view of the cabinet complete. This is presented so that the amateur worker will have a better

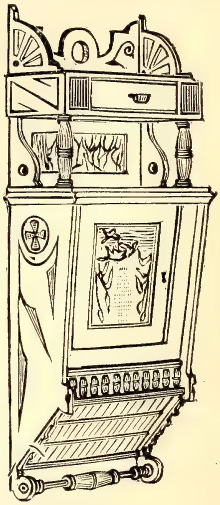

Fig. 5.

idea of the manner in which the work is put together.

Good glue, fine brads and care are all that is necessary to put the work together after it has all been gotten out properly.

Recipes for ebonizing are quite numerous, and one or two good ones can be found in back numbers of the YOUNG SCIENTIST, which, if closely followed, will give good satisfaction.

In conclusion, let me say that I will be happy to aid any of my young readers who may wish to make one of these cabinets, if they will acquaint me of their wants either through these pages cr in care of the editor.

The Aquarium.—New Mode of Aerating the Water.

SO important do we regard the subject of the aeration of water that we shall endeavor to present it to our readers in another way. Let us suppose a tank holding 12½ gallons of water or 100 pints. This amount of water would at the freezing point hold in solution—

Of nitrogen, ...	2 pints
" oxygen, ...	4 "
" carbonic acid, . .	179 "

But when the temperature of the water rises to 60° Fahr., these quantities are reduced to the following:

Nitrogen, ...	1.4 pints
Oxygen, ...	3 "
Carbonic acid, .	100 "

The pressure is assumed to be the ordinary pressure of the atmosphere. The quantity of gas absorbed increases with the pressure, as we see in the case of ordinary soda water, when a large quantity of carbonic acid is forced into the water by pressure, and remains quietly dissolved until this pressure is removed, when it at once escapes, causing a strong effervescence. The common "siphon" bottles show this very well.

The fact that as the temperature rises the gas which is dissolved in the water tends to escape, is well illustrated by a tumbler of common well water freshly drawn. Such water is generally cold; if brought into a warm room it at once gives off a large amount of gas, which appears as bubbles adhering to the sides of the tumbler.

So much for the capability of water to absorb gas. We now pass to a consideration of the conditions under which gas will be absorbed. It is evident that if no change is going on in the water, that is to say, if no plants or animals are present to absorb one kind of gas and give off another, any body of water will soon become saturated with air and will remain so. But if animals are present to use up the oxygen, and there are no plants to furnish a fresh supply, it will be found that the rapidity with which the water absorbs oxygen is exactly proportioned to the extent of surface exposed. Hence the practical conclusion that we must *spread out* the water of an aquarium if we would have it thoroughly aerated without the aid of plant life. And as in most aquaria the animals are kept in excess, it happens that those who have tanks which expose a large surface to the air, in proportion to the quantity of water present, generally have the best success. There are other conditions, however, which enter into this question, and which confer certain advantages on *deep* aquaria, and these we will consider hereafter. Meanwhile let it be understood that where water is aerated either by mere exposure or by mechanical means, everything depends upon the extent of surface which is exposed. Therefore, if you have gold fish in a glass globe, do not fill it too full. As soon as the water rises above the middle of the globe, the water surface diminishes, and the fish feel the want of air. No vessel of a globular shape should ever be filled more than two-thirds full.

When air is pumped into water, as was done in Barnum's old museum and in the tanks of the New York Aquarium, now also defunct, it will not do to pass the air into the water from the end of an open pipe, as is generally done. In this case the air passes through the water in large bubbles which expose very little surface in proportion to the amount of air that they contain, and consequently very little air is absorbed. Moreover, a large bubble ascends through the water more rapidly than a small one, and consequently time enough for absorption is not allowed. Some have sought to remedy this by a piece of wire gauze over the end of the pipe, but this does not answer, as, after passing through the gauze, the several

streams into which the meshes divide the air, unite and again form large bubbles. The true way is to allow the air to escape along the bottom of the tank from a series of fine holes bored in the pipe at a considerable distance from each other.

When the water in an aquarium needs aerating, and there is no contrivance provided of the kind we have just described, the best plan is to dip out some of the water and pour it back in a very fine stream. This is, however, rather tedious, and the temptation becomes very strong to allow the stream to get large and strong. Such a stream not only fails to accomplish the object in view, but it produces in the tank a commotion, which is very apt to do damage. Experience having taught us the objections to the ordinary plan, and all ordinary aquaria requiring a little occasional mechanical aeration, we devised the following method which we have found in practice to answer admirably. Make a bundle of straight, sound and clean straws about 12 to 18 inches long and two inches or more in diameter. Tie them firmly but not tightly together, and hold them slightly sloping, and with the lower end dipping in the water of the tank. Pour the water on the bundle of straw as near the top as possible, and allow it to flow down the bundle into the tank. Each straw and each space between the straws, acts as a Sprengel pump, or the blast of a Catalan forge; and not only is the water that is poured in thoroughly saturated with air, but a series of very minute bubbles are carried far down into the tank, serving to oxygenate the entire body of water. Two or three pitchers full poured into the tank in this way will make the water sparkling and pleasant.

Cheap and Useful.

WE find that we have on hand a few copies of the *first* edition of the "Amateur's Handbook of Practical Information for the Laboratory and the Workshop." It contains quite a large number of useful recipes and directions for mechanical processes. In order to close out the remainder of this edition, we will send a copy to any address, on receipt of seven cents in postage stamps.

Make Shifts for Young Microscopists.

ONE of our most common proverbs is that "accidents will happen," and unfortunately its truth is too frequently proved. Some time ago a young friend of mine broke the mirror of his microscope, and, of course, sent it some distance to an optician to have it replaced. While it was gone his microscope was laid aside as useless, although he was very anxious to examine some new slides and some fresh collections that he had made. Now came the time for a make shift.

I took a thin piece of fine grained wood (less than a quarter of an inch thick) and on it described a circle of the same diameter as the brass frame in which the mirror was mounted. This wood was then cut away so as to leave a thin circular disc which could be easily placed in the mirror-holder and could be adjusted to any angle. To one side of the disc I fastened a bit of looking glass, and the other side I covered with the whitest, clearest, paper I could find. Common paste answered very well to fasten both, and the microscope was again in good condition.

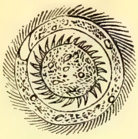
When examining a large object with a low power we used the white paper and this answered better than any mirror, as it gave a softer and more even illumination. For ordinary objects the bit of looking glass answered very well either by daylight or lamplight, but when a stronger light was needed in the evening, by lamplight, it was an easy matter to concentrate the light of the lamp by means of the bull's eye condenser, and this gave all the effect of a concave mirror.

And, by the way, let me here advise those readers of the YOUNG SCIENTIST who have microscopes with condensing lenses *attached*, to at once provide a separate stand for the lens. It is easily done by means of a common upright letter file and a bit of wood or even a cork, somewhat after the manner dercribed in the YOUNG SCIENTIST, vol. 1, page 70. A lens thus mounted is not only more easily applied to the illumination of opaque objects, but it can be used for other important purposes for which it cannot be employed when it is a fixture.

O. W.

Marvels of Pond Life—VI.

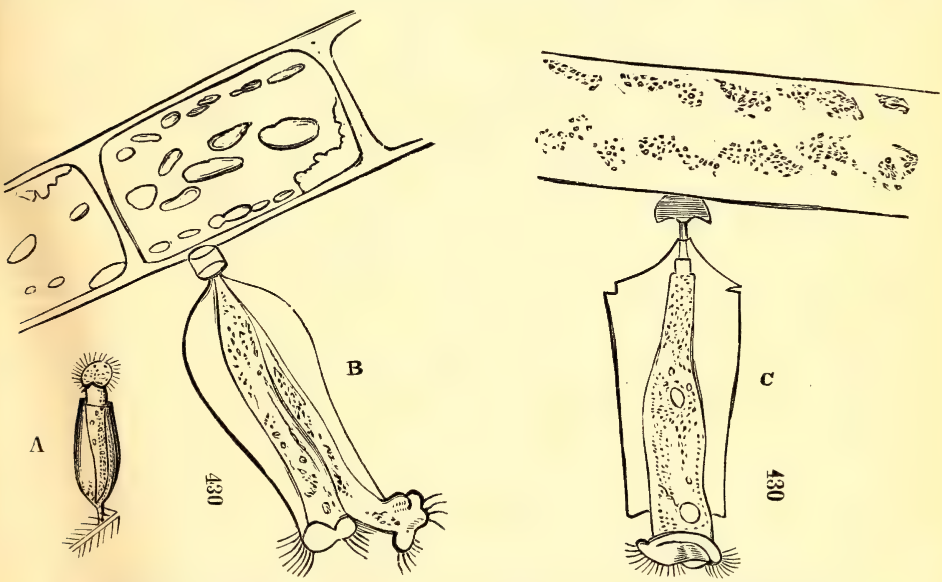
SEVERAL other Rotifers, with and without carapaces, were among the same* mass of confervæ, among them a *Metopidia*, with a firm shell, a forked jointed tail, and a projection in front which worked like a



Trichodina pediculus.

pickaxe among the decaying weed. There were likewise specimens of the long-necked animalcules (Trachelii), groups of Vorticella, some specimens of Volvox, and a small *Trichodina pediculus*, which, when magnified two hundred and sixty linear, was about the size of a sixpence and equally round. The edge was beautifully fringed with a circle of cilia; in an "Tenby," and described as the "Yellow Philodine," but this must remain in doubt, as it managed to escape before it could be secured.

By the 18th of the month the Vorticellids were much more plentiful, and their changes easily watched; many left their stalks while under the microscope, after which some rushed about like animated and demented hats, others twirled round like tee-to-tums, while others took a rest before commencing their wild career. But the common Vorticellæ were not the only or the most interesting representations of their charming order, for upon some threads of conferva were descried several elegant crystal vases standing upon short foot-stalks, and containing little creatures that jumped up and down like "Jack in the box." These were so minute, that a power of four hundred and thirty linear was advantageously brought to bear upon them. When elongated their bodies were somewhat pear-shaped, but more slender, and variegated with vacuoles and particles



A. Cothurnia imberbis—(Micrograph. Dict.') B and C. The specimens described in text.
The figures give the *linear* magnification.

inner circle was a row of locomotive organs, and the centre exhibited vacuoles constantly opening and shutting. This creature, as before explained, is often found as a parasite upon the polyps. On one occasion a glimpse was caught of a Rotifer similar in shape to the common wheel animalcule, but with a yellow inside. Possibly it was the object so beautifully delineated by Mr. Gosse, in his

* Figured in our January number.

of food. The mouths resembled those of Vorticellæ, and put forth circles of vibrating cilia. They were easily alarmed, when the cilia were retracted, and down they sank to the bottom of their vases, quickly to rise again. In one bottle there were two living in friendly juxtaposition. This was not a case of matrimonial felicity, nor of Siamese twins, but of *fission*, or reproduction by division. The original inhabitant of the tube finding himself too fat, or impelled by causes we do not

understand, quietly divided himself in two, and as the house was big enough, no enlargement was required. How many stout puffy gentlemen must envy this process; how convenient to have two thin lively specimens of humanity made out of one too obese for locomotion. Man is, however, sometimes the victim of his superior organization, and no process of "fission" can make the lusty lean.*

The bottles in which these creatures live, in happy ignorance that they are called by so crackjaw a name as *Cothurnia imberbis*, were described as *Carapaces* by Ehrenberg, but they bear no resemblance to the shell of a turtle or crab. They are thrown off by the animals who preserve no other connection with them than the attachment at the bottom.

The Micrographic Dictionary describes the family Ophrydinaas corresponding to Vorticellina with a carapace. Stein places them with Vorticellids, etc., amongst his Peritricha, which are characterized by a spiral wreath of cilia round the mouth.

Towards the end of the month a great number of black pear-shaped bodies (Stentor niger), visible to the naked eye, were conspicuous in some water from the Kentish Town ponds. Upon examination they were found to be filled with granules that were red by reflected, and purple by transmitted light. Each one had a spiral wreath of cilia, with a mouth situated like those of the stentors, hereafter to be described, but none of them became stationary, and in a few days they all disappeared. Stein divides Ehrenberg's Stentor igneus from S. niger; the creature described seem to have agreed with Stein's *igneus*, which he describes as having blood-red, lilac, cinnabar, or brown-red pigment particles, and as much smaller than his S. niger. In the same water were specimens of that singular Rotifer, the *Salpina*, about 1—150″ long, and furnished with a *lorica*, or carapace, resembling a three-sided glass box, closed below, and slightly open along the back. At the top of this box were four, and at the bottom three, points or horns, and the creature had one eye and a forked tail. Keeping him company was another little Rotifer, named after its appearance, *Monocerca rattus*, the 'One-tailed Rat.' This little animal had green matter in its stomach, which was in constant commotion. I ought to have observed that the Salpina repeatedly thrust out its gizzard, and used it as an external mouth. In the annexed sketch the Salpina is seen in a position that displays the dorsal opening of the carapace. Its three-cornered shape is only shown by a side view.

Salpina redunca.

Few living creatures deserve so well the appellation of "beautiful" as the *Floscularia ornata*, or Beautiful Floscule, although to contemplate a motionless and uncolored portrait, one would imagine that it exhibited no graces of either color or form. Mr. Gosse has, however, done it justice, and the drawing in his "Tenby" is executed with that rare combination of scientific accuracy and artistic skill, for which the productions of his pencil are renowned.

Probably the sketches in several works of authority representing the long cilia as short bristles, are merely copies from old drawings, from objects imperfectly seen under indifferent microscopes, and before the refinements of illumination were understood. Be this as it may, any reader will be fortunate if on an April, or any other morning, he or she effects the capture of one of these exquisite objects, although the first impression may not equal previous expectations, as the delicacy of the organism is not disclosed by a mode of using the light which answers well enough for the common infusoria.

When the Floscules, or other tubicolar Rotifers are specially sought for, the best way is to proceed to a pond where slender-leaved water-plants grow, and to examine a few branches at a time in a phial of water with a pocket-lens. They are all large enough to be discerned, if present, in this manner, and as soon as one is found, others may be expected, either in the same or in adjacent parts of the pond, for they are gregarious in their habits. With many, however, the first finding of a Floscule will be an accident, as was the case last April, when a small piece of myriophyllum was placed in the live-box, and looked over to see what it might contain. The first glimpse revealed an egg-shaped object, of a brownish tint, stretching itself upon a stalk, and showing some

* Balbiani in his 'Recherches sur les Phenomenes Sexuels des Infusoires.' speaks of the Vorticellids as the only Infusoria dividing longitudinally. In other species such appearances arise from conjunction.

symptoms of hairs or cilia at its head. This was enough to indicate the nature of the creature, and to show the necessity for a careful management of the light, which being adjusted obliquely, gave quite a new character to the scene. The dirty brown hue disappeared, and was replaced by brilliant colors; while the hairs, instead of appearing few and short, were found to be extremely numerous, very long, and glistening like delicate threads of spun glass.

Knowing that the Floscules live in transparent gelatinous tubes, such an object was carefully looked for, but in this instance, as is not uncommon, it was perfectly free from extraneous matter, and possessed nearly the same refractive power as the water, so that displaying it to advantage required some little trouble in the way of careful focusing, and many experiments as to the best angle at which the mirror should be turned to direct the light. When all was accomplished, it was seen that the Floscule had her abode in a clear transparent cylinder, like a thin confectioner's jar, which she did not touch except at the bottom, to which her foot was attached. Lying aside her in the bottle were three large eggs, and the slightest shock given to the table, induced her to draw back in evident alarm. Immediately afterwards she slowly protruded a dense bunch of the fine long hairs, which quivered in the light, and shone with a delicate bluish-green lustre, here and there varied by opaline tints.

The hairs were thrust out in a mass, somewhat after the mode in which the old-fashioned telescope hearth-brooms were made to put forth their bristles. As soon as they were completely everted, together with the upper portion of the Floscule, six lobes gradually separated, causing the hairs to fall on all sides in a graceful shower, and when the process was complete, they remained perfectly motionless, in six hollow fan-shaped tufts, one being attached to each lobe. Some internal ciliary action, quite distinct from the hairs, and which has never been precisely understood, caused gentle currents to flow towards the mouth in the middle of the lobes, and from the motion of the gizzard, imperfectly seen through the integument, and from the rapid filling of the stomach with particles of all hues, it was plain that captivity had not destroyed the Floscule's appetite, and that the drop of water in the live-box contained a good supply of food.

Sometimes the particles swallowed were too small to be discerned, although their aggregate effect was visible; but often a monad or larger object was ingulfed, but without any ciliary action being visible to account for the journey they were evidently compelled to perform. The long hairs took no part whatever in the foraging process, and as they do not either provide victuals or minister to locomotion, they are clearly not, as was supposed by early observers, representatives of the "wheels," which the ordinary Rotifers present. Neither can the cylindrical jar or bottle be justly deemed to occupy the position of the lorica, or carapace which we have before described. The general structure of the creature and the nature of its gizzard distinctly marked it out as a member of the family we call "Rotifers," but the absence of anything like "wheels" proves that those organs are not essential characteristics of this class.

Boring Wooden Handles.

Where many handles are to be bored, a half round bit, or a short piece broken off a carpenter's nose-bit and soldered into a small brass chuck to fit into the centre hole of the poppet head would be a good way of starting the holes. The handles should be held either in a clamp chuck or supported by a collar plate. I always use a common gimlet, taking care, however, not to work it as you would a cork-screw, viz., holding the bottle still and turning the screw round, but holding the gimlet firmly in the right hand and letting the tool handle shift at each half turn in the left hand as by this means you can feel whether it is running straight down the middle or not, and with a common gimlet you can apply force sideways to scoop the hole when you find any tendency to running out. The usual way is to burn the tools into their handles, and I see no objection to the practice, provided first the hole has been bored deeper than the point of the tang of the tool will go; and secondly, that all the charred portion of the wood is filed or scraped out of the hole before finally driving the tool in.

A much better plan is to have two or three floats or taper files cut on one side and one edge only with a few coarse teeth, and one or all made to cut backwards, for getting out the holes to suit the different dimensions of tangs. Almost any old tool that is small enough will do to make them of, and the notches may be and are better for being as uneven as you please; and the tool need not be hardened, or if hardened should be lowered to saw temper so that you can easily sharpen it with a file. The best wood for handles is ash, as it does not blister the hands. It must be well seasoned or the ferrules will drop off, and a dressing of linseed oil and yellow ochre, with alkanet root to give a red tinge, should be smeared on and allowed to dry on for a day or two before giving the finishing rub off.—*English Mechanic.*

THE

Young Scientist.

A Practical Journal for Amateurs.

With which has been incorporated
"THE INDUSTRIAL MONTHLY,"
"THE TECHNOLOGIST," AND
"HOME ARTS."

PUBLISHED MONTHLY AT 50cts. PER YEAR.

Postage free to all parts of the United States and Canada, except when delivered by letter carrier in New York City, in which case 12 cents per year postage is charged.

For Club Rates and Premium List see Prospectus.

Advertisements 30 cents per line, agate measure.

All communications should be addressed to

THE YOUNG SCIENTIST,
14 Dey Street, New York.

REMITTANCES.—Make all checks and postal orders payable to John Phin. U. S and English postage stamps received at full value for sums less than One Dollar. Canadian postage stamps are of no use to us, but Canadian silver and fractional currency will be received at full value.

Bills.

MANY of our subscribers complain that we stop their journals without due notification, and that if they were reminded of the expiration of their subscriptions they would at once remit. To remove all cause of dissatisfaction on this score we have printed little pink bills which were enclosed in the January number to all whose subscriptions expired. If you wish to renew, just write your name and address distinctly in the blank space left for this purpose and enclose it to us with fifty cents, which may be in postage stamps. The receipted bill will be enclosed in the following number of the YOUNG SCIENTIST.

Postage Stamps.

WE again call the attention of our subscribers to the fact, that while we take postage stamps of small denominations at full value, those of higher denominations are of no use whatever to us. We cannot sell them, except at a very great loss, and the post office will not exchange them for smaller denominations. Therefore, please do not send them.

Scientific Blunders.

A STRIKING illustration of the superficial character of the men who contribute "scientific" articles to the popular magazines occurs in a recent article on the telegraph in *Harper's Magazine.* The writer of this article illustrates his subject by water flowing through a pipe of three inches in diameter, which at a certain point forks into two branches, one being two inches and the other one inch in diameter. He gravely informs his readers that it is clear that the stream will divide at the branches, *one-third* passing through the smaller pipe and *two-thirds* through the larger one. If the scientific writer had consulted a table of areas, he would have found that the two inch pipe has four times the area of the one inch pipe, and consequently, one-fifth the volume of water (instead of one-third) will flow through the smaller pipe and four fifths through the two inch pipe. The writer in question seems to be about as ignorant of such matters as the owner of a certain stream who sold to a manufacturing company a supply of water regulated by a pipe of a certain diameter. In process of time the company found that they needed more water so they made a bargain with the owner whereby they were allowed to use a pipe of double the diameter by paying double the price. The owner of the stream did not know that a pipe of double the diameter would allow four times the amount of water to pass throught it, and consequently his ignorance of geometry resulted to him in an actual loss of dollars and cents.

Who Wants a Rifle?

WE have a very fine little Flobert rifle, the bore of which has been rifled so that it shoots with great accuracy. (The ordinary Flobert rifles are all smooth bores.) It is just the thing for small game or target practice, and we will give it to the first that sends us a club of fifty subscribers to the YOUNG SCIENTIST. Remember, this weapon will be given to the first that completes a club of fifty ; after that, those who wish a rifle as a premium, will have to be satisfied with the ordinary weapon.

Exchanges.

WE would again call the special attention of our subscribers to the very reasonable rules which we have laid down in the matter of exchanges. Some of our friends think that we ought occasionally to relax the rigor of these rules for their especial benefit. To such we can only say that if we change the rule for one we must do it for all. We would much rather give a subscriber free space in our advertising columns than break through our rules in regard to exchanges. So if your exchange has not appeared, just sit down again with the rules before you and write it out in conformity with them.

BOOK NOTICES.

Easy Experiments in Chemistry and Natural Philosophy. For Educational Institutions of all Grades and for Private Students. By G. Dallas Lind, author of "Methods of Teaching in Country Schools," etc. Price, 40 cents. New York: Industrial Publication Co.

The author of this work tells us in his preface that he "has spent much time in studying the art of illustrating the subjects of Chemistry and Natural Philosophy by means of simple and cheap apparatus." After a careful examination we feel no hesitation in saying that the result is very satisfactory. By the use of such simple things as ordinary bottles and preserve jars, the *use* at least of which may be obtained at almost any time for little or nothing; of corks, wires, and similar odds and ends, he shows how to perform a great many very instructive, interesting, and beautiful experiments. In many cases he uses very common and simple things for articles which are more elegant and convenient, if not more efficient. Thus for tubes he suggests the use of elder-stems; old cans, such as are used for preserving meats, oysters, etc., are frequently brought into play. It is really astonishing to see how much may be accomplished by means of such simple materials and a little ingenuity. An important feature of the book is the fact that the explanations are all scientifically accurate. To the teacher it will prove a means of enlivening many an otherwise dull recitation, while to the self-taught student it will be a source of endless amusement and pleasure.

The Phrenological Journal. S. R. Wells & Co., 753 Broadway, New York.

Whatever may be said about the special principles or theories advocated by this journal, it is an unquestionable fact that aside from such matters the subscribers get a full equivalent in the sprightly biographies and general articles which the journal contains. The tendency of the Phrenological Journal has always been towards purity and correct morality, and it should be a welcome visitor to every home.

Ward's Natural Science Bulletin.

This is a new candidate for favor, and one for which we predict a very great success. Prof. Ward is well known as the possessor of the largest commercial collection of really good minerals, fossils, and objects of natural history in general on this continent, and it therefore follows that material and means are at hand to make a good journal. Numbers 1 and 2 are before us, and they certainly promise well. Filled with able and interesting original articles, they are of great value to young people who are fond of collecting, and who wish to understand the scientific relations of the things they collect. The practical character of the contributions to this journal will be appreciated by those who read the article on Bird Skins, which we have transferred to another column.

The *Bulletin* is issued quarterly at the rate of fifty cents per year. It is printed in fine clear type on excellent paper, and we hope to make favorable arrangements for clubbing it with the YOUNG SCIENTIST.

Astronomy for Amateurs.

BY BERLIN H. WRIGHT.

(All calculations are for the Latitude of New York City.)

THE PLANETS FOR MARCH, 1882.

MERCURY.

This month Mercury may be seen in the east, before sunrise, as a morning star. He attains his greatest angular distance west of the Sun on the 21st, and accordingly is brightest from the 20th to 25th. This will not be as favorable an opportunity to see him as last month, but still he can be seen as he rises about one hour before the Sun.

VENUS.

During the latter portion of the month Venus may be seen in the west, just after sunset, setting, on the 10th, at 6.16 even.; 20th, 6.40 even., and 30th at 7.4 even.

MARS.

The flattened appearance, or rather gibbous phase of Mars will be more noticeable this month than again this year. He arrives at eastern quadrature April 1st, and the Moon passes 3° south of him on the 26th. Mars never has the horned or crescent phase, but appears slightly gibbous at quadrature. He passes the meridian on the 10th at 7.2 even.; 20th, 6.39 even., and 30th at 6.18 even. As Mars is two months in passing over one sign he will not be far from the place given last month,

JUPITER.

As it takes Jupiter an entire year to move over one sign, or 30°, his position, with respect to the stars, changes very slightly from month to month. He sets as follows: 10th, 11.5 even.; 20th, 10.37 even., and 30th, 10.7 even. He passes 1° south of the crescent Moon on the 23d.

FAVORABLE TIMES FOR OBSERVING THE PHENOMENA OF JUPITER'S SATELLITES.

(For an inverting telescope at 8h. 42m. even., New York City Time.)

On the 2d all will be upon the east, I., II., and III. close together, and IV. very distant. Again, upon the 16th none will be visible upon the west, and only II. and IV. upon the east, the others being in the planet's shadow or in eclipse. And again, on the 31st, all will be upon the east, only II., III., and IV. being visible, the last being very close to the planet. I. is in transit, which began at 8.19 P.M. On the 9th and 26th IV. may be seen at greatest distance west, and on the 1st and 18th greatest distance east. On the 7th, 8th, and 28th all will be upon the west side. On the 27th, at the above time I., II., and IV. may be seen at very nearly their true relative distances from the planet, and were III. as far again to the west it would be in the proper place.

The following are the visible eclipses of Jupiter's satellites which occur this month:

	D.	*H.*	*M.*			
I.—	2	6	36	even.	Reappearance,	E.
I.—	9	8	32	"	"	
II.—	12	6	53	"	"	
III.—	16	8	34	"	Disappearance,	E.
III.—	16	10	17	"	Reappearance,	E.
I.—	16	10	27	"	"	
II.—	19	9	30	"	"	
I.—	25	6	52	"	"	

SATURN.

The position of Saturn is better than last month, being lower; and we always feel repaid for looking at him. He sets as follows: 10th, 10.0 even.; 20th, 9.25 even.; 30th, 8.46 even. The Moon passes 4° north of him on the 22d.

ALGOL.

Algol may be seen at minimum brilliancy as follows:

February	15,	11.37 even.
"	18,	8.26 "
March	5,	4.30 morn.
"	8,	1.19 "
"	10,	10.8 even.
"	13,	6.57 "
"	28,	3.1 morn.
"	30,	11.50 even.

APPEARANCE OF THE HEAVENS AT 9 P.M. MARCH 20, 1882.

Looking southward very nearly all of the brightest stars are west of the Meridian. The Pleiades and Hyades in Taurus are near the western horizon; Gemini is above them, and Cancer is on the Meridian. As there are 12 signs in the Zodiac and 12 months in a year it is plain that the signs of the Zodiac must be 30° farther west than last month at the same hour. West of the Meridian, Leo, the Sickle, and Regulus are the first in the Zodiac; above them is Leo Minor, marked by one or two large thick clusters. Still east of Leo is Virgo and Spica, and above her is Berenice's Hair on a line and midway between the Sickle and Arcturus.

Looking northward, The Dipper is to the right of the upper Meridian; the Little Dipper (in Ursa Minor) to the right of Polaris; the principal stars of Draco below Polaris, and Cassipea's Chair at the left and a little below the Pole Star.

THE MOON, VII. 3D OR S. E. QUADRANT.

The region about the southern pole seems to possess several objects which bear marks of great age and hard usage. Just below Clavius is what appears to be the "ruins of a vast complex ring." The interior is depressed some 14,000 feet. Look for it just after First Quarter. It is number 195 on the map, and is called Maginus. At 200 begins a series of lunar circles extending northward and called the Great Crater Range. The Range consists of five walled plains of vast extent, and in some instances crater within crater, and the walls surmounted by lofty peaks. They seem to resemble to some extent existing features in the Andes and other ranges. The first one, 200, has lofty peaks on its rampart. The next one, 201, seems to be connected with both the one above and below, and has a high peak on the west side. The one below, 202, is 7,500 feet deep, and below this and just to the right lies one 32 miles across and with walls which rise in places 9,800 feet above the central cavity. Just east of this is the "Straight Wall." This curious formation has, we believe, been mistaken either purposely or otherwise for a work of art, and it is well calculated to deceive in that respect, for it is exceedingly regular, of uniform height, sloping gradually to the "ditch" at the base of the east side. Its height is about 1,000 feet, and it terminates at one end in a crater and at the other in a branching mountain. Best seen one or two days after First Quarter, or shortly after Third Quarter. The central member of the Lunar Circles, 204, is 65 miles across, and on its west side has a peak 13,600 feet high. Just below and a trifle to the right is 205, the most interesting of the series. It is over two miles in depth, and in consequence of this great depth its lowest recesses are almost always in darkness, being only free from shadow for five days in a lunation. It is a fine sight to see the Sun rise upon

the top of the peak, making a golden island in a sea of darkness. This central peak is 7,000 feet high. The next one northward is 207, 83 miles in diameter, with a central peak 4,000 feet high; and the last, 208, just south of the Moon's centre, is the largest of the chain, having a diameter of 115 miles. The interior plateau has a roughened surface, and at sunrise (Lunar) the surface appears like a vast lake roughened with waves, but these "waves" are about 100 feet high! Portions of its ramparts are 12,800 feet high, and some authorities claim there are 46 interior craters.

EPHEMERIDES OF THE PRINCIPAL STARS AND CLUSTERS, MARCH 21, 1882.

	H.	M.	
Alpha Andromeda (Alpheratz) sets	7	56	even
Omicron Ceti (Mira) variable "	8	4	"
Beta Persei (Algol) variable "	0	15	morn

Correspondence.

Starch as a Wood-Filler.

Ed. Young Scientist—In the December number of the YOUNG SCIENTIST corn starch is recommended as a filler for porous hard woods. In polishing black walnut and other dark woods I have used corn starch, and I have colored it with different materials; but I have always found that it became grey after a time and destroyed the beauty of the wood. What has been the experience of other readers of the YOUNG SCIENTIST?

A great many trials lead me to believe that any light, porous, and unalterable powder is good for this purpose. I have used fine chalk, ground up with coloring matter to suit, but the best that I have found is the powder used for making dynamite and soluble glass. I believe it is called *diatom earth.* It is of various colors, from almost pure white to dirty brown, and of course may be tinted to any shade we want it. It is unalterable, fills the pores well, sets quickly, and receives the final polish splendidly.

V. ARNISH.

An Addition to the "Blue Process."

Ed. Young Scientist—I have just read the article on "Blue Process of Copying Drawings" in the January number of YOUNG SCIENTIST, and think I can make a valuable addition, at least it has proved to be so to me, both in saving time and doing better work. In place of tracing cloth or tracing paper, I use ordinary paper of a quality hardly as good as that on which the YOUNG SCIENTIST is printed. Make a pen-and-ink drawing, allow it to dry, and then thoroughly saturate it with ordinary (so-called) olive oil (but which is really pea-nut oil); it dries quickly, and leaves the paper very clear.

A. W. BAILY.

Atlantic City, N. J., Jan. 12, 1882.

How to Soften Dry Bird Skins.

As usual with all processes in taxidermy, there are various ways in which a dried bird skin may be relaxed and made ready to mount, but I will describe the one I consider the simplest, easiest, and most effective.

1. *For Small Birds.*—Open the skin and remove the filling from the body, neck, and head. Tear some old cotton cloth into strips from an inch to two inches in width, wet them thoroughly in warm water, and wrap them round the leg and foot until it is covered with several thicknesses of the wet cloth, quite to the ends of the toes. Lift up the wing and put two or three thicknesses of wet cloth round the joint, and also between the wing and the body. Put some wet cotton or small rags inside the skin, wrap the whole skin completely in several thicknesses of cloth and lay it aside. If the bird is not larger than a robin, the skin will be soft enough to mount in about twelve to fourteen hours.

2. *For Large Birds.*—Under this heading it is necessary to place nearly all birds above the size of the robin, for the reason that the legs, being large and thick in comparison with the skin of the body, require extra treatment. The legs of some birds require several days' soaking, and were the skin of the body relaxed for the same length of time it would macerate and the feathers fall off. The legs of large birds must therefore be started first in the relaxing process.

Take, for example, the skin of a pheasant: cover the nails and beak with wax, if the skin

is an old one, or else they will flake off; wrap the feet and legs with wet cloths as described above, and let the skin lie without other wrapping for one day. At the end of this time the joints can be bent somewhat, and they should be manipulated until they bend easily. When they will do this, put wet cloths round the joints of the wings—in the body, neck, and head, and wrap the whole skin in a wet cloth. At the end of the second day the entire skin will be soft. The next step is to scrape all the hard parts of the skin and manipulate it until it is as soft as when fresh.

This process applies, with slight modifications, to all large bird skins, but, of course, the larger the bird, the longer it will take to relax. Sometimes the wings require soaking half as long as the legs in very large birds but care must be taken not to soak any feathered parts too long or the feathers are liable to drop out and cause serious trouble.

By the above process, skins may be softened and made ready to mount according to their size, about as follows: Wren to robin, in twelve to fourteen hours; ruffed grouse, two days; great blue heron, three days; bald eagle, four days; condor, five days; ostrich, six to eight days. Skins which are but a few months old will soften in about half the time they would require were they five years old, and if properly made in the first place will make as handsome mounted specimens as fresh skins.—*W. T. H., in Ward's Natural Science Bulletin.*

Cleaning and "Dipping" Brass.

The following process is said to be in use in the government arsenals: Make a mixture of one part common nitric acid and one-half part sulphuric acid in a stone jar; then place ready a pail of fresh water and a box of saw-dust. Dip the articles to be cleaned in the acid, then remove them into the water, after which rub them with saw-dust. This immediately changes them to a brilliant color. If the brass is greasy it must be first dipped in a strong solution of potash and soda in warm water. This dissolves and removes the grease so that the acid has the power to act.

Dyeing Ivory.

Almost all articles made of ivory look best when this material is left of its natural color—pure white. For some purposes, however, a contrast of color is desirable, and in such cases recourse must be had to dyeing. The following formula have been found to give good results. It is well to note that unpolished ivory takes color better than polished. Ivory must not be boiled long in liquids, and, according to Karmarsch, when taken out of hot liquid should be rapidly cooled by laying in cold water. Ivory is very sensitive to change of temperature, and while it will stand the treatment just mentioned, will not stand forcible blows when cold

1. *Black.* Boil for a short time in a strained solution of logwood, afterwards immerse in a solution of green sulphate of iron.

2. *Blue.* Immerse for a short time in a dilute solution of indigo-carmine.

3. *Yellow, a.* Immerse for a few minutes in water containing a little stannous chloride (protochloride of tin); afterwards in a hot, strained decoction of fustic.

b. Immerse for about fifteen minutes in a solution of chromate of potassium.

4. *Orange.* Treat as in the first process for yellow, but add to the fustic some shavings of Brazil-wood (Pernambuco-wood).

5. *Red, a.* Macerate cochineal in vinegar, and boil the ivory in the liquid for a few minutes.

b. Carmine dissolved in ammonia may be used. The tint is more purple-red.

c. Immerse in a very dilute solution of stannous chloride, and afterwards in a boiling solution of Brazil-wood. A little fustic turns the color to scarlet.

d. Ivory dyed as last directed is rendered cherry-red by immersion in a very dilute solution of potash.

e. Immerse in an alcoholic solution of alizarin-paste.

6. *Violet, a.* Dye red first; then immerse for an instant in solution of indigo-carmine.

b. Macerate in dilute solution of stannous chloride; then dip into a hot decoction of logwood. If the article be afterwards laid in water acidulated with a few drops of nitric acid, the color turns purple-red.

7. *Green, a.* Dye first yellow, and afterwards dip into solution of indigo-carmine.

b. Place for several hours in concentrated solution of chromate of potassium; afterwards expose to sunlight; this produces a dark, bluish-green tint.

Practical Hints.

Blue Prints.—An improved method of making cyanotypes, which gives a blue picture with a pure white ground, is described by Eder.

Well-sized paper is painted over with a brush with the following solution, freshly prepared; 30 volumes of gum Arabic solution (1 to 5), 8 volumes solution of citrate of iron and ammonia (1 to 2), 5 volumes solution of perchloride of iron (1 to 2). The mixture appears limpid at first, but soon grows thicker.

The paper is dried in the dark, then exposed

for a few minutes under a negative or drawing, and developed with a solution of one part ferrocyanide of potassium in 5 parts of water applied with a brush. It is fixed with dilute hydrochloric acid, 1 to 10, washed thoroughly and dried.—*Boston Journal of Chemistry.*

Sulphur as a Lubricator.—This substance has been long known as a most excellent anti-friction agent, and it has of late been very successfully used by the steamers of the North German Lloyds. The sulphur is mixed with oil or grease and applied like any ordinary lubricator. It combines with the fine metal dust worn off by friction and entirely prevents heating.

Liquid Glue.—The *Muster Zeitung* recommends, in preference to the treatment of glue with nitric acid, the following: So-called gelatine is dissolved in the water-bath in its own weight of strong vinegar, a quarter part of alcohol, and a very little alum. This glue remains liquid when cold, and is much used for cementing mother of pearl, horn, etc., upon wood or metal.

Treatment of New Files.—A new file should be used with a light pressure until the very thin sharp edges are worn off, after which a heavier pressure may be used with much less danger of the teeth crumbling at the top or breaking off at the base. Every filer should keep a partially worn file to use first on chilled surfaces or gritty skin of castings, or on a weld where borax or simiiar fluxes have been employed, or on the glazed surface of saws after gumming.

Stove Polish.—The fine polish given stoves by those skilled in the art, is produced as follows; Have a thin mixture of black varnish and turpentine; apply this with a paint or varnish brush to a portion of the stove; then with a cloth dust this over with pulverized British lustre or stove polish: then rub with a dry brush. The stove must be perfectly cold. The stove dealers buy the pulverized stove polish, which is carburet of iron, in 25-lb. packages. The process conducted in this manner is quite brief, but gives beautiful results.

Plate Polishing Paste.—The *English Mechanic* states that an excellent preparation for polishing plate may be made in the following manner: Mix together 4 ounces spirits of turpentine, 2 ounces spirits of wine, 1 ounce spirits of camphor, and ½ ounce spirits of ammonia. To this add one pound of whiting, finely powdered, and stir till the whole is of the consistency of thick cream. To use this preparation, with a clean sponge cover the silver with it, so as to give it a coat like whitewash. Set the silver aside till the paste has dried into a powder; then brush it off, and polish with a chamois leather. A cheaper kind may be made by merely mixing spirits of wine and whiting together.

To Bleach Straw.—Dissolve 108 grains (about 4 ounces) permanganate of potash (crystals) in 5 liters (or quarts) of hot water. Mix this solution in a tub of water until the water is a deep red. Enter straw which has previously been softened for several hours in a tepid bath of soda and well rinsed. Agitate the straw frequently. It will turn deep brown; if not, add some permanganate solution; leave it in till discoloration of the bath. When the straw is of a drab shade, rinse in cold water and enter in a bath of sulphurous acid. Make it of a sufficient degree to give forth odor. The discoloration of the straw takes place within 30 minutes, and generally turns a good white.

Science Gossip.

Ocean Wave Power.—The Swales Ocean Wave Power Company has incorporated, to furnish power by means of the action of ocean waves and tides with which to supply salt water for watering streets, flushing sewers, supplying public and private baths, extinguishing fires, and other public and private purposes; for driving machinery, compressing air, generating electricity, and for all manufacturing and commercial purposes.

A Great Telescope.—The observatory in the neighborhood of Nice, which is being erected at the expense of M. Bischoffsheim, is rapidly approaching completion. The great equatorial telescope is to be one of the largest in the world—perhaps the largest—as it will have an object glass three feet in diameter and a focal length of upwards of fifty feet. The construction of this monster telescope has been intrusted to MM. Paul and Prosper Henry, of Paris, and the total cost of the observatory will be more than $400,000 in American money.

Spiders Obstructing the Telegraph.—One of the chief hindrances to telegraphing in Japan is the grounding of the current by spider lines. The trees bordering the highways swarm with spiders, which spin their webs everywhere between the earth, wires, posts, insulators, and trees. When the spider webs are covered with heavy dews they become good conductors and run the messages to earth. The only way to remove the difficulty is by employing men to sweep the wires with brushes of bamboo, but as the spiders are more numerous and persistent than the brush users, the difficulty remains always a a serious one.

The Light of the Stars.—For a number of years the special work carried on at the Harvard observatory, under the direction of Prof. Pickering, has been the measurement of the intensity of the light of the heavenly bodies. Some of the results presented at a recent meeting of the Society of Arts, at the Institute of Technology, Boston, indicate measurements almost incredibly fine. The light which falls upon the earth from the satellites of Mars, for example, is about equivalent to what a man's hand on which the

sun shone at Washington would reflect to Boston. The labor of measuring the brightness of all the visible stars was begun two years ago. It has since gone on at the rate of about 40,000 a year, and will be completed next fall.

QUESTIONS AND ANSWERS.

Burning Iron Wire with a Battery.—Can anyone tell me how to heat or burn iron wire, and other experiments with the tin can battery described in vol. 1. H. A. K.

Ans.—In making this experiment three points require care: 1. See that the battery is in vigorous action. 2. When only one cell is used, see that the wires attached to the poles are short and stout, and well soldered to the copper and zinc. 3. See that the iron wire is short and very fine. The conductors or wires should not be more than twelve inches long, the solutions must be strong and warm. The finest iron wire—not thicker than a human hair—must be used. Such wire may be procured from most dealers in wire, or any watch maker can give you a bit of the balance-spring of a watch (not the main-spring). You should have no difficulty in burning a bit of fine wire with a single quart cell. Wollaston used to astonish his friends by igniting a piece of fine platinum wire by means of a battery made out of a lady's silver thimble.

How can brass drawing instruments be made so they will not tarnish and have that bad smell? An answer to the above will oblige a

Brass Monkey.

Ans.—We find that a correspondent of *Carpentry and Building* asks a similar question in regard to bird cages, and is answered as follows: "After thoroughly cleaning and removing the last traces of grease by the use of potash and water, the cage or other brasswork must be carefully rinsed with water and dried, but in doing it care must be taken not to handle any portion with the bare hand, nor anything else that is greasy. The preservative varnish may be shellac much diluted with alcohol, or it may be hard oil finish. We have tried the latter and found it to work very well. In either case the brass should be made pretty warm, and the varnish or shellac put on with a brush in as thin a coat as possible. In some places the stores sell the shellac varnish under the name of 'lacquer.' It is considerably thinner than the ordinary bronze shellac, and rather a nicer article. The proportion of shellac to alcohol is about two ounces of shellac to nine ounces of alcohol. Sometimes gamboge is used for a coloring matter to make the varnish more yellow, and sometimes dragon's blood." We fear, however, that any lacquer or varnish would soon disappear from articles which are handled as much as mathematical instruments. The best method is to have them nickel-plated, or if you are about to purchase a set, get them of German silver.

EXCHANGES.

Only those who are *yearly* subscribers, and whose names are entered on our books have the privilege of inserting exchanges.

Exchanges must be on separate slips of paper or postal cards. If mixed with business matter in letters or cards they are filed away and never reach the printer.

Exchanges must not exceed thirty words.

Buying and selling belong to the advertising department.

We reserve the right to omit the exchange column, when we have not room for it, and the amount of space at our disposal will regulate the number of insertions given to each *exchange*, the preference being always given to those who have not previously used our columns.

Model card press, chase 3¼ x 5¼, with 4 fonts type, cases, etc., for good foot lathe. Mills Day, 2 Farmington Av., Hartford, Ct.

French microscope, inclines to any angle, delicate fine motion, neat upright case, cost $17.50, for scientific books; send list to W. Fitz, P.O. Box 2852, New York.

Wanted, Quinby's New Bee Keeping, for Our Own Birds of the United States, by W. S. Baily; new. Joseph Anthony, Jr., Coleta, Whiteside Co., Illinois.

Printing type, small pica; large and small capitals, and small letters; 60 to 65 lbs., including two large cases; also gothic nonpariel, for trade. J. Siler, 1242 Broadway, St. Louis, Mo.

One years' copy of Aldine, cost $5.50, and German accordion, with instructions how to use it, cost $5.00, for offers. Chas. Dempwolf, 86 Benson St., Paterson, N. J.

A Novelty printing press, with type, prints a form 5 x 7 inches, cost $40.00, for a microscope, photographic apparatus, or offers. T. W. Patterson, Warsaw, N. Y.

$80 worth of (nearly new) printing material, minerals, fossils, Aboriginal relics, etc., for scientific books, good American watch, and offers. F. M. Farrell, Cobden, Union Co., Ills.

Rocks, minerals, fossils and fresh water shells for microscope stand, $20 to $75, also for objectives, turning lathe, type, and tools. D. D. Babcock, South Dansville, N. Y.

Mechanical Electricity, Medical Chemistry, by Robert Hare; Fruits and Farinacea, by Trall; Complete Herbalist, by O. P. Brown; for mounted objects for the microscope or offers. J. B. Playter, Bristow, Butler Co., Iowa.

Violin (cost $10) and 5-shot 32-cal. revolver (cost $4), for photo-camera lens and tube, watch, parlor rifle, extra well-bred canary birds, or offers. C. Maides, St. Louis, Mo.

To exchange for a wood-turning lathe or offers, a Young America Self-inking Printing Press, with type and outfit complete; chase 3 x 5 inches. Embury McLean, 318 Bloomfield St., Hoboken, N. J.

What offers for "Our First Century," cost $7.00, bound in sheep, over 400 illustrations, 1,000 pages; also small Ruby Magic Lantern, cost $1.50. Box 217, So. Manchester, Conn.

Magic lantern, in good order, condensing lens, 2½ in. diameter, 8 slides. For small photographic camera or offers. H. A. Giddings, 4 Union Place, Classon Ave., Brooklyn.

Printing press, type, etc., worth $13, for offers. E. G. Vogeley, 1010 Bradford St., Pittsburgh, Pa.

Fifty canary birds, with and without crests; fancy poultry, conch shells, strombus alatus. For small printing press, books on natural history, or offers. Frank Lattin, Gaines, N. Y.

A good plain 7 shot revolver, 22 calibre, for a Students' inch or half-inch objective. Frank F. Colwell, Urbana, Ohio.

Wanted, Printing press and type, in good order, chase 6 x 10, or larger; will give hardware, tools, scroll saw, or designs. Chas. E. Little, 59 Fulton St., New York.

Photo outfit, tools, chemicals and apparatus, etc., etc.; wanted scientific books, apparatus, etc.; send lists. A. B. Campbell, Box 59, South Dayton, Catt. Co., N. Y.

Stuffed birds, insects or job printing (cards, labels, etc.) for mounted objects for the microscope. James P. Melzer, Milford, N. H.

A ring stand, filtering stand, calcium light jet and a gas holder, holding one cubic foot, for a phonograph. D. P. Smith, 59 Park Place, New York.

THE Young Scientist

SCIENCE IS KNOWLEDGE. KNOWLEDGE IS POWER.

A PRACTICAL JOURNAL OF

HOME ARTS.

VOL. V. NEW YORK, MARCH, 1882. No. 3.

The Lucifer Match.

COMMON and apparently simple as is the lucifer match, it is not half a century since it was invented, and strange to say the originator is entirely unknown, although he has probably done as much to add to the happiness of the human race as any other inventor. Matches have been in use for hundreds of years, but it was only about the year 1835 that a really serviceable match—one that could displace the old flint and steel—was brought forward. Two years before that, Faraday, the greatest chemist of his age, published a new edition of his book on Chemical Manipulation, and in that he advises the use of flint and steel, or the old "dipping match" as the best means of getting a light. We may, therefore, safely conclude that a really good match was not known at that time. The following story about the origin of the match is now going the rounds of the press, but is evidently a mere story:

"A famous chemist, Mr. Isaac Holden, on rising early one morning to pursue his studies in science, was exceedingly incommoded by the difficult method of striking a light from flint and steel, and the idea occurred to him to use some explosive firework. When delivering a lecture shortly afterwards, he said that of course he knew, as other chemists did, the explosive material that was necessary in order to procure instantaneous fire; but it was very difficult to obtain a light on wood by that explosive, and the idea occurred to him to put sulphur upon the explosive mixture, which he demonstrated. A person in the lecture room who knew a chemist in London wrote to him about it, and in a few days lucifer matches were issued."

"Explosive fireworks" had been used for this purpose for a long time before the modern match was invented. The old "dipping" matches consisted of a wooden splint, the end being coated with sulphur and tipped with a mixture of chlorate of

potassa, sugar, and sulphide of antimony. These matches, when dipped into sulphuric acid, took fire and gave a light. The acid was kept in a bottle filled with asbestos, which served the purpose of a sponge, and such bottles with one hundred matches were sold for seven shillings and sixpence, or nearly $2.00!! Just think of paying two dollars for a box of matches!

The modern match was invented when somebody made an emulsion of phosphorus in glue, adding nitre, red lead, antimony, etc., to color and improve it. Sulphur had been used long before, both on plain matches, used for getting a light from flint, steel and tinder, and on the old chlorate matches, but this did not make them a really serviceable article. The use of phosphorus in the way we have described at once gave us a useful match, easily ignited by gentle friction on any rough surface. The old flint and steel was by no means a bad implement for getting a light. In skilful hands it is certain, simple, and always obtainable. It would be far better than the matches described by Holden. They required great effort to ignite them, and very frequently failed. We have seen boxes of these old matches, and only about one-third of them would ignite by the most careful handling. And we have made them after the best prescriptions of Accum and others with like results. The modern lucifer match can be used by a child, and it is a great pity that the name of the inventor is unknown.

Glass Working.

THE young experimenter will find frequent difficulties and meet with many accidents in working glass, owing to the fact that when this substance is not properly "annealed" it is very brittle—the slightest scratch causing it to fall to pieces. Two hollow balls of glass (like those used for shooting),* if made of good material and well annealed, may be suspended by strings like two pendulums, as shown in Figure 1, and then if one be drawn aside into the position shown in the dotted lines, and allowed to fall, the other will rebound as if made of india rubber! We have been surprised ourselves, and have surprised many an audience by the force with which the two balls may be allowed to strike together without breaking. But if the balls be unannealed, they will not stand this rough usage. Glass is annealed by heating it

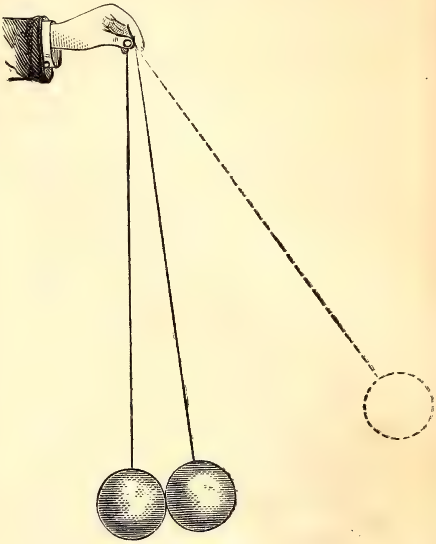

Fig. 1.

very hot—almost to the point of softening—and then allowing it to cool slowly for several days. To make the cooling very gradual, a special oven called a "leer" is provided, and all good glass ware must be passed through the leer in order to make it stand. When the glass makers are hurried, they sometimes do not give sufficient length of time to the process, and the consequence is that the glass soon breaks in pieces. Indeed, so easily broken are articles in this condition that we have frequently had jars and other vessels fall to pieces of themselves. But even when not so bad as this it will often happen that if the article is a tumbler or dish, it breaks when hot water is poured into it, and if it is a lamp chimney, it cracks on the slightest provocation. A

*The balls used for shooting are made expressly *to be broken*. Therefore no care is taken to anneal them, and they will not answer for this experiment. Balls, specially annealed for the purpose, are sold by dealers in philosophical apparatus.

common recipe for annealing lamp chimneys is to boil them in water, and allow them to cool gradually. This does not heat them enough, however. If salt were dissolved in the water it would be still better, and if the chimney were placed in an oven which was allowed to cool very gradually, it would be better still. It is the *gradual cooling* from a high temperature that does the work, as the particles of glass then have time to arrange themselves properly.

An example of glass in a condition the very opposite of the balls just described, may be seen in the Rupert Drops, shown in Fig. 2. These are drops or tears of

Fig. 2.

glass which have been allowed to fall into water so as to cool them suddenly. The outer portion of the glass then contracts before the inner portion has time to cool, and the consequence is that the surface is in a state of high tension. If we take one of these drops, and break off the slender tail, the shock of the fracture will be communicated to every part of the drop, and it will fall to pieces, as shown in Fig. 3. Sometimes the glass arranges itself in centres of compression, as shown in Figures 4 and 5.

When the glass is broken in this way, its volume suddenly enlarges and the pieces fly from each other with considerable force. It is best, therefore, to wrap the drop in paper before breaking off the end. That which a moment before was a solid, clear piece of glass will now be found to be a fine powder.

The effect of the expansion, etc., may be curiously shown by breaking the drop in a thin glass bottle filled with water. The force of the blow will be transmitted

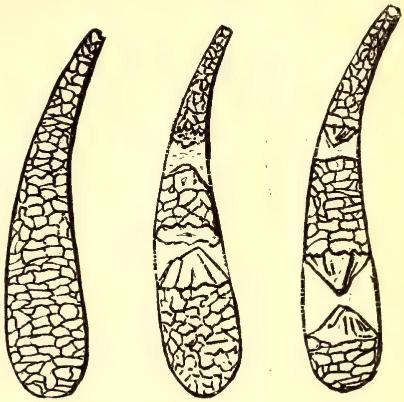

Fig. 3. Fig. 4. Fig. 5.

through the comparatively incompressible water, and the glass vessel will be broken. This is a very curious and startling experiment.

Another form of annealed glass is seen in the so-called Bologna phial, of which we shall give a description in our next article. It forms a most curious and useful study, teaching us a great deal that is very important and useful about the care and management of glass vessels.

Unconscious Effort.

DAILY instances of unconscious effort present themselves to us, and would be noted and understood if we only knew how to detect them. Amongst those who have had no training in the more delicate manipulations of science and of refined life, we constantly see the unconscious exercise of great and unnecessary force. Such persons, if asked to wipe a delicate glass vessel, will twist it in two and wonder why it breaks! They have probably applied a force of several pounds where as many ounces would suffice, and a fracture is the result. The table tipper and spiritualist take advantage of this and get them to place their hands on a

table, and lo, the table tips or moves off, and they declare that they are exerting no force! Faraday early detected this curious psychological peculiarity, and met it by the simple but very scientific process of indicating and measuring the force applied. In every case in which motion was produced, it was found that the exact amount of force required to produce this motion was applied, but, strange to say, when the indicator was exposed to the view of the operator or "medium," so that he or she was fully aware of the power they exerted, no force was applied and no motion resulted. Strange to say, women seem to be more liable to the exertion of this unconscious effort than men, and this both in the case of "mediums" and in ordinary life. In our experience we have found that girls are far more apt than boys to put forth a superabundance of strength and "break things." And yet they will tell you that they did not use much force, and no doubt believe it.

One of the most singular instances of unconscious effort is that long ago described by Sir David Brewster. Writing to Sir Walter Scott, he says:

"One of the most remarkable and inexplicable experiments relative to the strength of the human frame is that in which a heavy man is raised with the greatest facility, when he is lifted up the instant that his own lungs and those of the persons who raise him are inflated with air. This experiment was, I believe, first shown in England a few years ago by Major H., who saw it performed in a large party at Venice under the direction of an officer of the American navy. As Major H. performed it more than once in my presence, I shall describe as nearly as possible the method which he prescribed. The heaviest person in the party lies down upon two chairs, his legs being supported by the one and his back by the other. Four persons, one at each leg, and one at each shoulder, then try to raise him, and they find his dead weight to be very great, from the difficulty they experience in supporting him. When he is replaced in the chair, each of the four persons takes hold of the body as before, and the person to be lifted gives two signals by clapping his hands. At the first signal he himself and the four lifters begin to draw a long and full breath, and when the inhalation is completed, or the lungs filled, the second signal is given, for raising the person from the chair. To his own surprise and that of his bearers, he rises with the greatest facility, as if he were no heavier than a feather. On several occasions I have observed that when one of the bearers performs his part ill, by making the inhalation out of time, the part of the body which he tries to raise is left, as it were, behind. As you have repeatedly seen this experiment, and have performed the part both of the load and of the bearer, you can testify how remarkable the effects appear to all parties, and how complete is the conviction, either that the load has been lightened, or the bearer strengthened by the prescribed process.

At Venice the experiment was performed in a much more imposing manner. The heaviest man in the party was raised and sustained upon the points of the forefingers of six persons. Major H. declared that the experiment would not succeed if the person lifted were placed upon a board, and the strength of the individuals applied to the board. He conceived it necessary that the bearers should communicate directly with the body to be raised. I have not had an opportunity of making any experiments relative to these curious facts; but whether the general effect is an illusion, or the result of known or of new principles, the subject merits a careful investigation."

In an illustration we give another method of performing this experiment. This method has been recently revived in France, and is as follows: Two individuals place the forefingers of their right and left hands under the feet of the person to be lifted; two other persons place the forefingers of their hands under his elbows, and another places the same finger under his chin. At the command *one, two, three!* each person makes a vigorous effort upward, and the individual under experiment is lifted up with surprising ease. Although the experiment never fails to astonish those who behold

it, there is really nothing wonderful about it when we reflect upon it. It is a simple example of equal distribution of weight. A man weighs on an average about 150 pounds, and each finger, therefore, lifts about 21½ pounds. And as the total effect is so surprising, the individual performers are unable to estimate the amount of force used, and consequently exert much of it unconsciously. Each one thinks that he applies only two or three pounds.

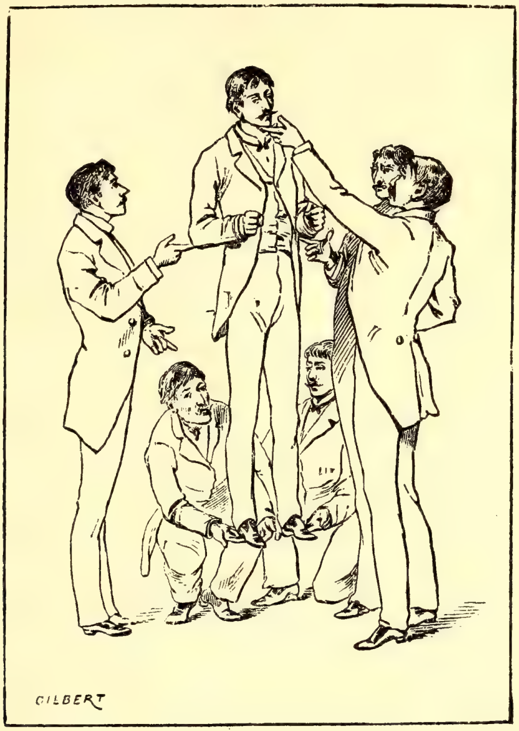

ILLUSTRATION OF UNCONSCIOUS EFFORT.

To Design a Monogram.

SCARCELY anything seems so easy as to design a monogram, yet we see very few successful ones, the most of them being a mass of mixed-up letters and ornament, of which we can find neither the beginning nor the end. There is a law regulating the designing of everything, and it is this law which the true designer keeps in mind and applies to his work; the effects of obedience to this law and its violation are seen as clearly in the design for a monogram as in the design for a cathedral.

First, there should be harmony of composition—that is, the letters should so emphasize, subdue, or control each other that the composition should impress us as compact, appropriate, and, being so, beautiful.

Second, there should be no unnecessary ornamentation; there should be a quiet and peace about the design which will always please the truly artistic. Looking at some designs, we get the impression that ornament was so plentiful that the designer saw no other means of consumption than that of burying his designs in it, for we see that there is a mass of curves, angles, shades and leaves, but nothing else.

Third, simplicity of lettering is an important requisite, as there should be no possibility of mistaking an E for a G or C, and the boundaries or outlines of the letters should be well defined.

Fourth, the order of sequence of the letters should be carefully attended to.

The common idea is, that a certain number of letters are given with which to make a pleasing design, and so far, that impression is right; but there is something beyond this. There is the art of so

placing the letters that one can distinguish at a glance the first, the central, and the last letter. Now the rule to be observed to secure this result is as follows: The *last* letter of the monogram must be the principal feature, and must be the largest, the boldest, and the heaviest letter; then the *first* letter must be the next in size, but the lightest in outline and color; then the *central* letter must be the smallest and of an intermediate tint. If the monogram is of four letters, the two intermediate must be the same size and the second letter lighter in outline and color than the third.—*Art Amateur.*

The French Diapason.

THE Italian Theatre, in Drury Lane, London, has adopted our normal diapason. This is a very small victory for France, and one which should be followed by others more desirable. It is, however, a *victory*, and we find pleasure in recording it for want of a better one. We will recall to those who may have forgotten it, what the normal diapason is. It is the agreement in virtue of which the note obtained by a sonorous body which makes 870 vibrations in a second at the temperature of 15 degrees centigrade, is called *La*. This *La* is the note which is situated a little above the first half of the key-board of a piano; it is the one which is the medium of female voices; and also the one which is given by the next string to the treble string upon a violin. It is easily seen that *one* of the notes of the gamut having been settled, the positions of all the other notes will be established, since they have regular intervals between them. It would be the same with a mason's ladder hung up on a wall; if you should take one of its rounds and elevate or lower it a certain distance, all the other rounds would be either elevated or lowered in the same proportion. Since the 1st July, 1859, the diapason at 870 vibrations has been obligatory by ministerial decree. It was quite time, however, to stop its ascensional progress. From the last of the Seventeenth century the diapason without official restraint went up, up, up! We can judge of this from the following table:

In 1699,	*La* =	808	vibrations.
1713	"	812	"
1780	"	818	"
1810	"	846	"
1823	"	862	"
1830	"	871	"
1836	"	882	"
1868	"	891	"

Why did they select *La* as the standard note before regulating the degree of acuteness of all the others? Thereupon hangs a legend which I must relate to you. In the last years of the Seventeenth century the society of the "Vingt-Quatre violins de la chambre du Roy" began to feel the urgent need of having a fixed diapason. But where find that point which should be an unchangeable standard for reference at all times? Chance furnished it. In fact it was found only when the open *La* of the fiddlers corresponded in a small measure with the note given by the great clock (*bourdon*) of Notre Dame (taking into consideration, of course, an interval of several octaves). It was a happy coincidence, and they profited by it.

If eventually the *La* had not ceased ascending, to the great detriment of singers voices, the blame should not have rested upon any but the instrumentalists, who, in their desire to shine, elevated more and more the diapason of their instruments. In 1859, that is to say, in the epoch of the ministerial decree, which took the position of police of the gamut, the diapason of Paris was 896 vibrations; that of Lille 904; that of Milan 900; that of St. Petersburg 903; that of Berlin 903. Sooner or later it will be seen that all musical Europe will sustain the rule of our diapason, and stand in unison with us, which will constitute a sort of European equilibrium.—*Courrier des Etats-Unis.*

Girls as Housekeepers.

BEGIN with your own things and your own place. That is what your mother will tell you if your rush to her, enthusiastic with great intentions, and offer to relieve her of half her housekeeping. Reform your bureau drawer, relieve your closet pegs of their accumulation of garments out of use a month or two ago. Institute a clear and cheerful order, in the midst of which you can daily move; and learn to keep it. Have your little wash cloths and your sponges for bits of cleaning; your furniture brush and your feather duster and your light little broom and your whisk and pan; your bottle of sweet oil and spirits of turpentine, and piece of flannel to preserve the polish or restore the gloss where dark wood grows dim or gets spotted. Find out, by following your surely growing sense of thoroughness and niceness the best and readiest way of keeping all fresh about you. Invent your own processes; they will come to you. When you have made yourself wholly mistress of what you can learn and do in your own apartment, so that it is easier and more natural for you to do it than to let it alone—so that you don't count the time it takes any more than that which you have to give to your own bathing or hair dressing—then you have learned enough to keep a whole house, so far as its cleanly order is concerned.—*Ex.*

SONGS OF THE SCIENCES.

Oh! merry is the Madrepore that sits beside the sea,
The cheery little Coralline hath many charms for me;
I love the fine Echinoderms of azure, green and gray,
That handled roughly, fling their arms impulsively away;
Then bring me here the microscope and let me see the cells,
Wherein the little Zoophyte like garden floweret dwells.

We'll take the fair Anemone from off its rocky seat,
Since Rondelitius has said when fried 'tis good to eat;
Dyspeptics from Sea Cucumbers a lesson well may win,
They blithely take their organs out and then put fresh ones in.
The Rotifer in whirling round may surely bear the bell,
With Oceanic Hydrozoids that Huxley knows so well.

You've heard of the Octopus, 'tis a pleasant thing to know,
He has a ganglion makes him blush not red, but white as snow;
And why the strange Cercaria, to go a long way back,
Wears ever, as some ladies do, a fashionable "sack;"
And how the Prawn has parasites that on his head make holes,
Ask Dr. Cobbold, and he'll say they're just like tiny soles.

Then study well zoology, and add unto your store
The tales of Biogenesis and Protoplasmic lore;
As Paley neatly has observed, when into life they burst,
The frog and the philosopher are just the same at first.
But what's the origin of life remains a puzzle still,
Let Tyndall, Haeckel, Bastian go wrangle as they will.

Punch.

Marvels of Pond Life.—VII.

NOTICEABLE currents are not always produced when the mouth of this Floscule is fully expanded. On one occasion, one having five lobes was discovered standing at such an angle in a glass trough that the aperture could be looked down into. The position rendered it impossible to use a higher power than about two hundred linear, but with this, and the employment of carmine, nothing like a vortex was seen during a whole evening, although a less power was sufficient to show the ciliary whirlpools made by small specimens of *Epistylis* and *Vaginicola*, which were in the small vessel. The density of the integument was unfavorable to viewing the action of the gizzard, but it could be indistinctly perceived. The contractions and subsequent expansions of the cup, formed by the upper part of the creature, may be one way in which its food is drawn in, but there is no doubt it can produce currents when it thinks proper. Sometimes animalcules in the vicinity of Floscules whirl about as if under the influence of such currrents. Some may be seen to enter the space between the lobes, swim about inside, and then get out again, while every now and then one will be sucked in too far for retreat.

Above the gizzard in the Horned Floscule,* I have seen an appearance as if a membrane or curtain was waving to and fro, while another was kept in a fixed perpendicular position. Mr. Gosse, speaking of this genus, observes "that the whole of the upper part of the body is lined with a sensitive, contractile, partially opaque membrane, which a little below the disk recedes from the walls of the body, and forms a diaphragm, with a highly contractile and versatile central orifice. At some distance lower down another diaphragm occurs, and the ample chamber thus enclosed forms a kind of *crop*, or receptacle for the captured prey."

"From the ventral side of the ample crop that precedes the stomach, there springs in *F. ornata* a perpendicular membrane or veil, partly extending across the cavity. This is free, except at the vertical edge, by which it is attached to the side of the chamber, and being ample and of great delicacy, it continually floats and waves from side to side. At the bottom of this *veil*, but on the dorsal side, are placed the jaws, consisting of a pair of curved, unjointed but free *mallei*, with a membranous process beneath each."

* The Horned Floscule (*F. cornuta*) which I have found, and which bred in a glass jar, were not so large as those described by Mr. Dobie, as quoted in "Pritchard's Infusoria." Mr. Dobie's specimens were 1—40″ when extended; mine about half that size, five-lobed, and with a long slender proboscis, standing in a wavy line outside one lobe. Mr. Dobie also describes an *F. campanulata*, with five flattened lobes. The "Micrographic Dictionary" pronounces these two species "doubtfully distinct." I have three or four times met with a variety of *F. ornata*, in which one lobe was much enlarged and flattened, but they had no proboscis. In what I take for *F. cornuta*, the horn or proboscis has sometimes been a conspicuous object, and at others so fine and transparent as to be only visible in certain lights.

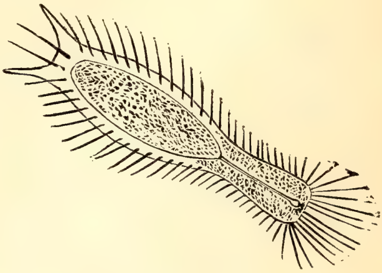
The Beautiful Floscule could always be made to repeat the process of retreating into her den, and coming out again to spread her elegant plumes before our eyes, by giving the table a smart knock, and her colors and structure were well exhibited by the dark-ground illumination, which has been explained in a previous page.

An object like this should be watched at intervals for hours and even days, especially if the eggs are nearly ready to give up their infantile contents. This was the case with the specimen described, and after a few hours a young Floscule escaped, looking very much like a clumsy little grub. After a few awkward wriggles the new-born baby became more quiet, and on looking at it again at the expiration of seventeen hours, it had developed into the shape of a miniature plum-pudding, with five or six tiny lobes expanding their tufts of slender hair. unforunately its further proceedings were not seen, or it would have been interesting to note the growth of the foot, and the formation of the gelatinous tube, which is probably thrown off in rings.

To view the details of the structure of a Floscule, it must be placed in a live box or compressorium, and if specimens are scarce, they should not be allowed to remain in the limited quantity of water those contrivances hold, after the observations are concluded, but should be carefully removed, and placed in a little vial, such as homœopathists use for their medicine. By such means an individual may be kept alive for many days. It is also interesting to place a little branch of the plant occupied by Floscules or similar creatures, in a glass trough, where they may be made quite at home, and their proceedings agreeably watched by a one-inch or two-thirds power. These troughs,* which can be obtained of the optician, should be of plate glass, about three inches long, nearly the same height, and about half an inch wide. If narrower, or much taller, they will not stand, which is a great inconvenience. The pieces of glass are stuck together with marine glue, and a very simple contrivance enables the plants or other objects to be pressed near the front, and thus brought into better view. A strip of glass, rather narrower than the width of the trough, is dropped into it, and allowed to fall to the bottom. Then a piece of glass rather shorter than the trough, and rather higher than its front side, is placed so as to slope from the front of the bottom towards the back at the top. The piece of glass first dropped in keeps it in the right position, and the trough is thus made into a V-shaped vessel, wide at the top and gradually narrowing. Any object then placed in it will fall till it fits some part of the V, where it will remain for observation. A small wedge of cork enables the movable piece of glass to be thrown forwards, until it assumes any angle, or is brought parallel to the front of the trough.

A power of five or six hundred diameters generally enables a movement of small globules to be seen at the extremity of the lobes of the Floscule, and the gizzard may be made plain by dissolving the rest of the creature in a drop of solution of caustic potash. It also becomes more visible as the supply of food falls short. Mr. Gosse describes the body as "lined with a yellowish vascular membrane," and young specimens exhibit two red eyes, which may or may not be found in adults. When these eyes of Rotifers are not readily conspicuous, they must be sought for by opaque illumination, or by the dark-ground method which, especially with the parabola, is successful in bringing them out.

Naturalists, and possibly the specimens also, do not always agree in the number of lobes assigned to the "Beautiful Floscule," and although it is easy enough to count them in *some* positions, the observer may have to exercise a good deal of patience before he is certain whether they are five or six. For a long evening only five could be discerned in the specimen now described, but the next night six were apparent without difficulty or doubt. The hairs also will not appear anything like their true length or number, unless the object glass is good, and great care is taken not to obscure them by a blaze of ill-directed light.

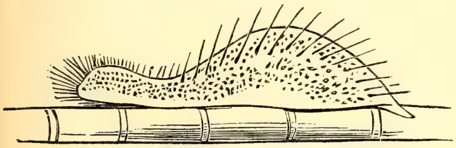


Chætonotus larus (swimming) × 520.

After the Floscules had been sufficiently admired and put aside, for observations to be repeated on future occasions, a Rotifer attracted attention by his merry-andrew pranks, throwing himself in all directions by means of two long and ex-

*The shallow cells with thin sliding covers devised by Mr. Curteis (of Baker's), are still more convenient when no pressure is required, and the objects are small. When not under the microscope they can be kept full of water by immersion in a tumbler.

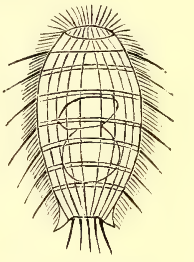
tremely mobile toes attached to his tail-foot. Then came a creature swimming like an otter, thrusting his head about on all sides, and looking much more intelligent than most of his compeers of the pond. Looked at vertically, he was somewhat slipper-shaped, the rounded heel forming his head, then narrowing to a waist, and expanding towards the other end, which projected in a fork. All round him were long cilia, which were conspicuous near the head, and a fine line indicated the passage from his mouth to the stomach, which seemed full of granular matter. Presently he took to crawling, or rather running, over a thread of conferva, and then his back was elegantly arched, and his cilia stood erect like the quills of a porcupine. This was the *Chœtonotus larus.*



Chætonotus larus (crawling) × 520.

In Pritchard's "Infusoria," the views of those writers are followed who rank this animal amongst the Rotifers, and place it in the family *Icthidina.* To help out this theory, the cilia upon the ventral surface are imagined to form a "band-like rotary organ;" but in truth they bear no resemblance whatever to the so-called wheels of the ordinary Rotifers, nor is there anything like the gizzard which true Rotifers present. Ehrenberg treated it as a Rotifer, and Dujardin placed it among the Infusoria, in a particular class, comprehending symmetrical organisms. The "Micrographic Dictionary" remarks that its "structure requires further investigation,"* and while the learned decide all the intricate questions of its zoological rank, the ordinary observer will be pleased to watch its singular aspect and lively motions. Its size, according to the "Micrographic Dictionary," varies from 1–710″ to 1–220″, and while its general proceeding may be watched with an inch or two-thirds object glass, and the second eye-piece, a power of five hundred linear (obtained by a quarter or a fifth) is required to make out the details of its structure. If placed in a live-box with threads of conferva, and a little decayed vegetation, it may be observed to grope about among them, and shake them like a dog.

We have said that water-fleas were among the inhabitants of a bottle filled at the pond, and as they go the way of all flesh, it is common to find some odd-looking animalcules ready to devour their mortal remains. These are creatures shaped like beer-barrels, upon short legs, and which swim with a tubby, rolling gait. Looking at one of these little tubs lengthwise, a number of lines are seen, as though the edge of each stave projected a little above the general level, and transverse markings are also apparent, which may be compared to hoops. This is the *Coleps hirtus*, which differs from the usual type of Infusoria, by being symmetrical, that is, divisible into two equal and similar halves. The dimensions of this species vary from 1-570 to 1-430, and its color varies from white to brown. It has been observed to increase by transverse self-division, and has two orifices, one at each end, for receiving food and ejecting the remains. It often requires some little trouble to get a good view of the cilia, which are arranged in transverse and longitudinal rows. A power of one hundred and fifty linear is convenient for viewing it in motion, but when quiet under pressure, one of five or six hundred may be used with advantage.



Coleps hirtus.

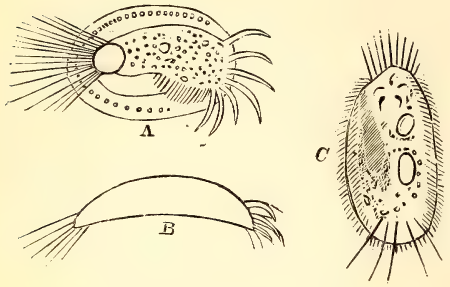
Among the rubbish at the bottom of the bottle, in which the coleps was found, was a minute dead Rotifer, the flesh of which was fast disappearing, but upon being examined with a power of nine hundred and sixty diameters, it was observed to swarm with extremely minute *vibriones*, the largest only appearing under that immense magnification like chains of bluish-green globules, not bigger than the heads of minikin pins, while the smallest were known by a worm-like wriggling, although their structure could not be defined. These *vibriones* are probably members of the vegetable world, and they always appear when animal matter undergoes putrefaction.

M. Pasteur has brought forward elabor-

* See a valuable paper by Mr. Gosse, "History of the Hairy-backed Animalcules," Intellectual Observer, vol. v., p. 387, in which the known species are described and reasons given for following Vogt and ranging them with the Turbellarian worms.

ate experiments to show that the development of the yeast plant is an act correlative to alcoholic fermentation, and in like manner the growth of *vibriones* may stand in correlation to putrefactive decomposition.

Ehrenberg considered them animals,



A, Euplotes (patella); B, side view of ditto; C, Stylonichia.

and fancied he detected in them a plurality of stomachs; but the vegetable theory is the more probable, at any rate of the species under our notice, which is often seen, though not always so minute.

At this time two interesting animalcules were very plentiful—the *Euplotes patella*, and *Stylonichia*, both remarkable as exhibiting an advance in organization, which approximates them to the higher animals. In addition to cilia they possess *styles*, which take the place of the limbs of more elaborately-constructed creatures, and give a variety to their means of locomotion. The *Euplotes* is furnished with an oval carapace covering the upper surface, which in different individuals, and probably at different ages, exhibits slightly varied markings round its margin, which in the specimen drawn above consisted of dots. They can run, climb, or swim, and exemplify a singular habit which several of the infusoria possess, that of moving for a little time in one direction, and then suddenly, and without any apparent cause, reversing it. If the reader is fond of learned appellations, he can call this *diastrophy*, but we do not know that he will be any the wiser for it.

The Stylonichia are oval animalcules, surrounded by cilia, and having moreover a collection of styles, both straight and curved, the latter called *uncini*, or little hooks. They swim steadily on, and then dart back, but not so far as they have advanced, and may be seen to keep up this fidgety motion by the hour together. Pritchard tells us Ehrenberg found that a single animalcule lived nine days; during the first twenty-four hours it was developed by transverse self-division into three animals; these in twenty-four hours formed two each in the same manner, so that by self-division only (without ova), these animalcules increased three or four-fold in twenty-four hours, and *may thus produce a million* from a single *animalcule in ten days*. Such are the amazing powers of reproduction conferred upon these humble creatures, powers which are fully employed when the surrounding circumstances are favorable, and which, in the aggregate, change the condition of large masses of matter, and bring within the circle of life millions upon millions of particles every minute of the day.

Cultivating the White Water Lily.

IN the superbly kept gardens of Europe, the aquarium or tank for water plants is an important feature, and adds greatly to the beauty of the grounds. But even where the premises are small a well kept water tank, on a much larger scale than the ordinary parlor aquarium, is a very pleasing object, and we have many attractive plants which would render them very interesting and beautiful—for example, the arrow head, the calla and others.

Many of our readers will ever hold in remembrance the sweet fragrance of the white water-lily, so common in every clear, quiet country pond. If they only knew how easily it could be cultivated, we believe that very many of them would prepare and be quite as proud of their water-lilies as of any other of their floral premises. The roots may be easily obtained from the dealer's and sent by mail, packed in damp moss. The roots should be kept constantly moist until planted.

To do that take an old tub or barrel sawed in two, that will hold water, set it either on top or in the ground, one-third filled with a mixture of garden soil, sand and well-rotted manure. The roots should be set in this mixture, and water added in small quantities, so as not to disturb the earth until the tub is filled. Very soon the handsome round leaves, four or five inches in diameter will make their appearance and fill the tub. The loss of water by evaporation should be made good from time to time, and ere long the blossoms will appear and delight everyone with their beauty and fragrance. Care should be taken not to allow the annual increase to crowd the vessel, or the floral display will be diminished. The pure white flowers will be as perfect and beautiful and fragrant as the camellia, closing at night and opening in the morning. The bloom of lilies thus transplanted are generally a little smaller than in their native pond, but this is an advantage rather than an objection.

THE

Young Scientist.

A Practical Journal for Amateurs.

With which has been incorporated
"THE INDUSTRIAL MONTHLY,"
"THE TECHNOLOGIST," AND
"HOME ARTS."

PUBLISHED MONTHLY AT 50*cts. PER YEAR.*

Postage free to all parts of the United States and Canada, except when delivered by letter carrier in New York City, in which case 12 cents per year postage is charged.

For Club Rates and Premium List see Prospectus.

Advertisements 30 cents per line, agate measure.

All communications should be addressed to

14 Dey Street, New York.

REMITTANCES.—Make all checks and postal orders payable to John Phin. U. S and English postage stamps received at full value for sums less than One Dollar. Canadian postage stamps are of no use to us, but Canadian silver and fractional currency will be received at full value.

Correction.

BY an unfortunate accident Fig. 5, page 20, in our last issue was turned upside down. As we shall have this error corrected in the electrotype plate, future impressions will be correct. To find out whether the cut is right side up or not, compare it with Figures 1 and 3, which are correct in all editions of the YOUNG SCIENTIST.

Workshop Receipts.

THIS is a closely printed volume of 450 double column pages, forming a complete encyclopædia of practical information for the amateur and the mechanic. It is too well known to need commendation. We have a few copies on hand which we offer as premiums to those who send us ten new subscribers to the YOUNG SCIENTIST and five dollars. Almost any boy can secure this number of new names by a little effort among his friends.

Astronomy for April.

SOME of our readers may miss the astronomical article in this number. The astronomy for March will be found in the February number, and as the April number will go to press early in March it will be in ample time to place in the hands of all our readers the astronomy for April.

Postage Stamps.

WE again call the attention of our subscribers to the fact, that while we take postage stamps of small denominations at full value, those of higher denominations are of no use whatever to us. We cannot sell them, except at a very great loss, and the post office will not exchange them for smaller denominations. Therefore, please do not send them.

Who Wants a Rifle?

WE have a very fine little Flobert rifle, the bore of which has been rifled so that it shoots with great accuracy. (The ordinary Flobert rifles are all smooth bores.) It is just the thing for small game or target practice, and we will give it to the first that sends us a club of fifty subscribers to the YOUNG SCIENTIST. Remember, this weapon will be given to the first that completes a club of fifty ; after that, those who wish a rifle as a premium, will have to be satisfied with the ordinary weapon.

Correspondence.

Snow Crystals.

Ed. Young Scientist—For the past two years I have been making crystals a study, and have made observations on nearly all the snow storms, but the storm of February 4, in this part of Pennsylvania, was something unusual. The storm from beginning to end was noticeably very fine. Close examination with microscope revealed that these small flakes were all solid crystals, six sided prisms, with a hexagon plate on each end, giving them the appearance of a dumb-bell. Although this form of crystal is nothing new, still in the two years of my observation I have never before discovered one until then, when they seem to come all at once.

W. T. ALAN.

Greenville, Pa., Feb. 14th, 1882.

BOOK NOTICES.

Practical Microscopy. By George E. Davis, F.R.M.S., F.I.C., F.C.S. Illustrated with 257 Woodcuts and a Colored Frontispiece. Price, $3.00. For sale by Industrial Publication Co., 14 Dey street, New York.

This work has just been issued in London, and forms a handsome small 8vo. of 335 pages. The author states that his "object in presenting this work to the student of microscopy is to supply, at a reasonable cost, a book written upon somewhat similar lines to Quekett's 'Practical Treatise on the Use of the Microscope,' the second and last edition of which appeared in 1852." Unfortunately for the author's accuracy of statement, the second edition of Quekett's work was not the last. The third, with considerable improvements, appeared in 1855. It is evident, therefore, that Mr. Davis has not made a very careful study of his proposed model. This, however, is a matter of trifling consequence, as it would hardly be worth while at this day to follow Quekett's work closely as a model.

That there is an urgent demand for a thorough work on the use of the microscope and the preparation and mounting of objects, is pretty generally felt. We hardly think, however, that the present volume quite realizes the necessary conditions, for, although three times the price, it really does not contain more matter than some dollar books now in market—the type being large and the lines double-leaded. Besides this, the work is largely made up of extracts from periodicals and catalogues (not always acknowledged), and there is a want of accuracy which is to be regretted. Thus, Tolles' address is still Canastota, instead of Boston; the vertical illuminator of Prof. H. L. Smith is credited to Powell & Lealand, and Beck; the searcher for diatoms is directed to examine the stomachs of "fish, especially crustaceans and molluscs;" and the student is cautioned against attempting to make preparations of skin, tongue, liver, lung, etc., until he has become a moderately expert experimentalist—advice which bears almost too great a resemblance to the old lady's caution not to go near the water until the art of swimming had been learnt. We are glad to see that the author has carefully read "How to Use the Microscope," as several unacknowledged passages and figures show.

But notwithstanding the somewhat unsatisfactory nature of the book, it contains enough matter, which can only be otherwise found in scattered form, to make it a welcome addition to the libraries of most microscopists.

Cleaning Engravings.

The following directions for cleaning engravings we find in several exchanges, all claiming it as original: If brown spots and rings of mildew have not made their appearance, float the engraving face downward for 24 hours on a large quantity of water, in a vessel perfectly free from grease and soil of all kinds. Lift it from the water on a perfectly clean sheet of glass, drain, transfer to blotting paper without touching it, then transfer to fresh blotting paper, dry, rub with bread, as is done in drawings, and iron. If the stains are bad, or are not removed by this plan, place the engravings in a shallow dish, and pour water over them until perfectly soaked. Carefully pour off the water and replace it with a solution of chloride of lime (1 part liq. calcis chlorate to 39 parts water). As a rule the stains disappear as if by magic. If not, pour on the spot pure liq. calcis chlorate; if that does not succeed, add a little acid nitro-hydro-chlor. dil. As soon as the stain disappears, wash the engraving carefully with successive portions of water until all the chlorine is removed. Then steep it in a weak solution of glue and gelatine, which may be colored with coffee grounds, to give the engraving a yellow color. Then dry between blotting paper, under a weight, and iron, with a sheet of clean paper between the iron and the print. Small grease spots may be removed by putting powdered French chalk over them, a piece of clean blotting paper over the chalk, and a hot iron over that. If the stains are larger, benzine must be used, applying it in a circle around the stain before touching the stain itself.

Iridescent Copper.

A new invention for coating iron and steel with iridescent copper, says the *Revue Polytechnique*, is the work of Dr. Weil, of Paris. First, 35 parts of crystallized sulphate, or an equivalent amount of any other salt of copper, are precipitated as hydrated oxide, by means of caustic soda or some other suitable alkaline base; this oxide of copper is to be added to a solution of 150 parts of Rochelle salts, and dissolved in 1,000 parts of water; to this 60 parts of best caustic soda, containing about 70 per cent. NaO, is to be added, when a clear solution of copper will be formed. The object to be coppered is to be cleaned with a scratch-brush in an alkalino-organic bath, attached as a cathode, immersed in the coppering bath, and treated with the usual precautions, when it will become rapidly coated with an adherent film of metallic copper. As the bath gradully loses its copper, oxide of copper, as above prepared, should be added, to maintain it in a condition of activity, but the quantity of copper introduced should not ordinarily exceed that above prescribed, as compared with the quantity of tartaric acid the bath may contain. If the quantity of copper notably exceeds this proportion, certain metallic irisations are produced on the surface of the object. These effects may be employed for ornamental and

artistic purposes. According to the time of the immersion, the strength of the current and the proportion of copper to the tartaric acid, the iridescences may be produced of different shades and tints, which may be varied or intermingled by shielding certain parts of the object by an impermeable coating of paraffine or varnish, while the iridescent effect is being produced on the parts left exposed. All colors, from that of brass to bronze, scarlet, blue, and green, may thus be produced at will.—*Metal Worker.*

An Artificial Sun.

The most powerful artificial light in the world has just been constructed by Messrs. Chance Bros. & Co., at Smethwick, near Birmingham, Eng., for the South Head Lighthouse, near Sydney, New South Wales. It is a first order dioptric, revolving light, with the electric arc. The lamp has a special arrangement of prisms for securing vertical divergence of the beam. It is over six feet in diameter, and the height is about nine feet, and it is said to be the first time such dimensions have been applied to illumination by the electric arc. The lamp has a power of about 12,000 candles in the focus of light, and the merging beam has a luminous intensity exceeding 12,000,000 candles. The light will give flashes around half the horizon at intervals of a minute, and will make a complete revolution every 16 minutes. On an average, the light will be visible at a distance of 40 to 50 miles. At an exhibition of its power recently given at Smethwick, the light was so intense that it oould hardly be endured by the naked eye.

Iridium for Electric Lamps.

A promising improvement has been made in electric lighting by substituting electrodes of iridium for the carbon pencils hitherto almost exclusively used as poles in exhibiting the voltaic arc. Iridium is fusible only in the arc from a very powerful battery, and by keeping the intensity of the current below a given point, the metal can be maintained at a temperature of about 4,000° F., which is far below its melting point, though high enough to add the light of an intense incandescence to the brilliancy of the arc itself. At this temperature the iridium points remain completely unchanged, and the variations and flickerings due to the rapid wearing away of carbon pencils are entirely absent in the new light; while the consistency with which the source of illumination keeps its place peculiarly adapts it for use in the focus of the Fresnel lenses, or the parabolic reflectors which, in lighthouses, or in similar situations, take their place. The process by which the iridium, naturally a gritty and intractable powder, is formed into pencils for use in lamps is an ingenious adaptation of a patent issued long ago for making the same metal into points for gold pens, and depends upon the property which iridium possesses of forming a compound with phosphorus, which can then be melted at a temperature of about 3,000° F.—about the fusing point of iron—and molded into masses which can be subsequently dephosphorized, and regain the original infusibility of the pure metal.

The Largest Refracting Telescope in the World.

For the present our friend, Alvan Clark, is outdone by his Hibernian rival, Howard Grubb. The 26-inch refractor at Washington, the largest previously made, must yield the palm to the 27-inch one lately finished at Dublin for the Royal Observatory at Vienna.

It is a curious fact that the Emerald Isle should have produced the largest refractor as well as the largest reflector, which our readers are aware is Lord Rosse's. The former was ordered by the Austrian Government in 1875, and the mechanical portions of the instrument were nearly finished in 1878. The making of the object-glass was delayed by the difficulty of getting perfect material. Messrs. Feil, of Paris, furnished several sets of glass discs for the purpose before any were found free from flaws and defects. Much time and labor were lost in working some of these discs into such shape that their imperfections could be detected. It was not until March of the present year that the instrument was complete in all respects, and its performance approved by the commissioners appointed by the Austrian Government to test it.

The tube of the telescope is made of steel plates riveted together, and measures 33½ feet in length, with a diameter of 36½ inches in the middle, tapering to 27 inches at one end and 12 at the other. The weight of the tube with its attachments is between six and seven tons, but the whole weight can be easily moved by the observer with one hand. The great dome in which the telescope is to be placed is also of steel, consisting of a double shell of thin plates with light ribs and girders between, the whole forming a cellular structure somewhat like that of the top and bottom of the Britannia Tubular Bridge. Great strength and stiffness are thus secured, while the weight is reduced to the minimum. The dome, 45 feet in diameter, weighs only about fifteen tons, and when set up on temporary supports at Dublin could be moved round with a tractive force of seventy

pounds. It will probably "work" even more easily in its proper position at Vienna.—*Boston Journal of Chemistry.*

Nicknames of the States.

The following are some of the nicknames of the States:

Alabama, Lizard State; Arkansas, Tooth-pick; California, Golden State; Colorado, Rover; Connecticut, Wooden Nutmeg; Delaware, Musk-rat, otherwise the Blue Hen's Chicken; Florida, the Beaver State; Illinois, Sucker; Indiana, Hoosier; Iowa, Hawk-Eye; Kansas, the Jay-Hawker; Kentucky, Corn Cracker; Louisiana, Creole; Maine, Fox, otherwise Lumber; Maryland, Gray Vampire; Michigan, Wolverine; Minnesota, Gopher; Mississippi, Tadpole; Missouri, Puke; Massachusetts, Bay State; Nebraska, Big Eaters; Nevada, Sage Hen; New England, Land of Steady Habits; New Hampshire, Old Granite; New Jersey, Blue, sometimes Clam Catcher; New York, Knickerbocker or Empire; North Carolina, Old Tar; Ohio, Buckeye; Oregon, White Foot, or Hard Case; Pennsylvania, Broadbrim, or Keystone State; Rhode Island, Gun Flint; South Carolina, Palmetto, or Weasel; Tennessee, Whelp; Texas, Beef-Head; Vermont, Green Mountain; Virginia, Pitch; Wisconsin, Badger.

French Polishing.

Dissolve shellac in spirits of wine, with the aid of heat, till it is about as thick as cream. Make a ball of cotton wool, with a bit of soft rag over it. On this pour a few drops of polish; cover with another bit of soft linen rag, on which put one drop of raw linseed oil; hold this against the work as it revolves in the lathe until dry, moving it to and fro all the time; repeat the process till the work shows a polish; then, with a rag on which is just a drop or two of spirit of wine, or with the same rubber, on which is a drop or two of spirit, go over it again till it is all bright, with no smears. If not lathe work, you will have to rub round and round in circles over the surface, never stopping, but taking up the rubber *en route* generally; the best way is, with the last circling motion, to sweep it clear of the work. It is a laborious job if on a large surface, especially as the polish will at first sink in, and when you next inspect it you will find it terribly fallen off from its pristine beauty. You should let it then get dry and hard, and, with the very finest No. 00 sandpaper, rub it down to a general smooth, but, of course, wholly unpolished face. Then go at it again. Do not use much oil, only enough to prevent the rag sticking in its course. For the last coats use the finish thinner. The object of the rub with the spirit only is to get rid of dull spots caused by the oil, and to insure a very thin coat of polish; some oil the work first, and let this soak in for some days till dry, then polish. It will be found that the less oil the better.

Bullet Holes in Windows.

Dr. Balch, in his review of the medical evidence given on the second trial of Jesse Billings, Jr., says that a ball fired from a rifle through a window pane will make a hole one-third smaller than the ball itself. He has proved this by repeated experiments. He dwells on this at some length; but after all it was a fact that was fully known and discussed as long ago as the time when Jesse Strang shot Mr. Whipple through a window in the old house at Cherry Hill.—*Albany Evening Times.*

Practical Hints.

Improved Starch Polish.—Spermaceti, 1 part; gum arabic, 1 part; borax, 1 part; glycerine, 2½ parts; water, 21½ parts; and a sufficient quantity of perfumed alcohol to produce an emulsion. About three teaspoonfuls of this emulsion are required for about one-quarter of a pound of starch.

Bronzing Copper.—At the Paris mint, medals are bronzed by boiling them for a quarter of an hour in the following solution: pulverized verdigris, 500 grammes; pulverized sal-ammoniac, 475 grammes; strong vinegar, 160 grammes; water, two liters. An untinned copper boiler is used, and the medals are separated from each other by bits of glass or wood.

Black Dye for Wood.—The following new process is published in the *Pharmaceutische Zeitschrift fur Russland:* First sponge the wood with a solution of chlorhydrate of aniline in water, to which a small quantity of copper chloride is added. Allow it to dry, and go over it with a solution of potassium bichromate. Repeat the process twice or thrice, and the wood will take a fine black color, unaffected by light or chemicals.

Amber Varnish.—Amber varnish is usually prepared by roasting the amber and adding hot linseed oil, after which turpentine can be mixed if required. But if small quantities are required you might proceed as follows:—Dissolve the broken amber, without heat, in the smallest possible quantity of chloroform, or pure benzine. Heat the linseed-oil, remove it from the fire, and pour in the amber solution, stirring all the time. Then add the turpentine. If not quite clear, heat again.

Treatment of Hydrofluoric Acid Wounds.—A. E. Robinson writes to the editor of the *Chem. News* that one of his assistants had been seriously burned by hydrofluoric acid, the face

wounds being very severe and deep, and that he has treated them first with a paste of chalk and water, and afterwards with a mixture of chalk and olive oil. The latter mixture allayed the pain and suffering considerably, and materially hastened the healing process, the face-wounds being now healed over, forming a perfectly healthy skin,

Paper for Silver-Ware.—The *Archiv der Pharmacie* gives the following formula for making paper for wrapping up silver: Six parts of caustic soda are dissolved in water until the hydrometer marks 20° Baume. To the solution add four parts of oxide of zinc, and boil until it is dissolved. Add sufficient water to bring the solution down to 10° Baume. Paper or calico soaked in the solution and dried will effectually preserve the most highly-polished silver articles from the tarnishing action of the sulphuretted hydrogen which is contained in such notable quantities in the atmosphere of all large towns.

Cleaning Lime-Encrusted Pipes.—A correspondent of the *American Manufacturer* writes: "As a sort of 'shop kink' I give you a curious experiment tried on an engine water-supply pipe that had become choked up with lime encrustation. After hammering it for an hour or two, and kindling a fire all over it, without any result, one end was plugged up, and about a pint of refined coal oil was poured in the other—all it would hold—leaving it to stand all night. The next morning the entire mass slid out, a solid lime core. Before trying this we thought of throwing the pipe away as useless, and getting a new one."

Blacking Brass.—A correspondent of the *English Mechanic* says: I have tried all the various recipes recommended—nitrate of silver, platinum bichloride, etc.—but never found any work so satisfactorily and cheaply done as by the reduction of nitrate of copper to the oxide. I find the best way of using is to apply the solution to the brass to be blacked with a camel-hair brush, previously slightly heating the metal; then to raise the heat until the requisite color is produced; finishing by rubbing with a soft rag, and either oiling or lacquering. I can confidently recommend this as the very best method of producing that good black seen in first-class optical goods, observing that the process will not do for soft-soldered articles, as the heat necessary to produce the black is greater than the melting-point of soft solder.

Damascus Steel.—Perhaps one of the best methods which have ever been discovered for tempering steel, resulting in hardness, toughness, and elasticity combined, is that followed in hardening the blades of the famous Damascus swords. The furnace in which the blades were heated was constructed with a horizontal slit by which a current of cold air from the outside entered. This slit was always placed on the north side of the furnace, and was provided on the outside with a flat funnel-shaped attachment by which the wind was concentrated and conducted into the slit. The operation of tempering the blades was only performed on those days of winter when a cold strong north wind prevailed. The sword-blade when bright red hot was lifted out of the fire and kept in front of this slit and by this means was gradually cooled in the draft of air. It acquired the proper degree of temper at the single operation,

QUESTIONS AND ANSWERS.

How can I bronze plaster casts? A. B. C.

Ans.—The plaster must first be rendered non-absorbent by filling the pores with size. When this is dry, give a very light coat of gold size or boiled linseed oil, and when this has become nearly dry, but is still sticky, dust bronze powder over it. When the whole is thoroughly dry, dust off the loose powder with a brush, especially from the crevices and projecting points.

Will some one tell me how to make a stereotype of a line of type?

Ans.—Lock up the line of type, as if for printing, and oil the surface with any kind of oil, which must, however, be carefully wiped off, merely leaving the surface greasy. Pour over it a cream of plaster-of-Paris and water, such as is used for taking casts, and when this has become hard, lift it off and dry it at a temperature not higher than that of boiling water. Make another plaster cast with a perfectly smooth face, dry it also, and tie the two together. See that the plaster moulds are quite dry, or you will have trouble. Make a sprue or channel like that through which the lead is poured into a bullet mould, but much longer, so as to give a good "head" of metal. This will force the metal into all the fine lines and keep it free from air bubbles. Then melt some stereotype metal (old stereotypes are best for amateurs) in a ladle and pour it into the mould. When cold, dress up the casting and fasten it on a block.

Angle-Worms and St. Elmo's Fire.—You will confer a favor on us by answering the following questions: "How do angle-worms dig their holes?" and "What is the St. Elmo Fire?"
P.S.—We do not know what angle-worms are.

Ans.—Several species of worms are known as "Angle-Worms," but the term is generally applied to the common earth worm. They can hardly be said to "dig" holes, but the means by which they penetrate the ground is singularly interesting. Between the particles of earth they insert the very fine end of their lip, which they are able to draw out to a very long and slender thread. This is armed with spines, so that it cannot be drawn back, except at the will of the animal. As soon as the front part of the animal has been fairly embedded it is made to swell up and enlarge the hole sideways, and the mucus or slime given off by the animal, cements the sides of the hole and makes it smooth. In soft ground this process is repeated rapidly, but where the soil is very hard the operation is a slow one. Still, it is only a question of time even in the hardest ground.

St. Elmo's fire is the silent discharge of electricity from the clouds upon an elevated point, It appears as a luminous brush upon masts and spires, especially where these are furnished with metal points, such as weather vanes, etc.

EXCHANGES.

Only those who are *yearly* subscribers, and whose names are entered on our books have the privilege of inserting exchanges.

Exchanges must be on separate slips of paper or postal cards. If mixed with business matter in letters or cards they are filed away and never reach the printer.

Exchanges must not exceed thirty words.

Buying and selling belong to the advertising department.

We reserve the right to omit the exchange column, when we have not room for it, and the amount of space at our disposal will regulate the number of insertions given to each *exchange*, the preference being always given to those who have not previously used our columns.

Blow-pipe set (cost $10), large illustrated family Bible (cost $7.50), for Wood's Botany, Dana's Geology, or printing press and type. H. W. Noble, Box 134, South Dansville, N. Y.

Wanted, offers for fossil shells from the west coast of Africa. A. W. Seward, 187 E. 71st St.

I have a number of birds' eggs I should like to trade for other birds' eggs; send for list of trading eggs. A. G. G., Box 26, Summit, New Jersey.

For a microscope stand or offers, a 36-inch turning lathe (new) and a number of scientific books; send for list. A. Kendall, Somerville, Mass.

Wanted services of amateur printer with small office (or large), in exchange for an interest in a well-established weekly paper, good size. Eagle Office, Plymouth, N. H.

American Agriculturist microscope, new, cost $15, for amateur photographic apparatus, lever watch, 22 calibre breech-loading sporting rifle or magic lantern of equal value. Wm. A. Walker, Rockland, R. I.

I. T. Bell, Franklin, Pa., has back numbers of Scientific American, Forest and Stream, and Young Scientist, good flute, chessmen, books, etc., for good magic lantern, revolver, scarce coins, or offers.

A steel spring bracket-saw, 2 doz. saw blades, and about 1 doz. patterns for a good stylographic pen or offers; send postal before exchanging. Geo. Oakley, Rutherford, N. J.

A new 40 diameter microscope, corals, and minerals, for a stylographic pen, air gun, or offers. J. McBride, 54 Garley St., Chicago.

A rosewood banjo, 11 inch head, 12 nuts, fully strung, together with lot of dime banjo music and instructions, for microscope, Webster's Unabridged, monkey, squirrel and cage, or offers. J. DeWitt Clark, P. O. Box 37, Brooklyn, N. Y.

For self-inking printing press and type, one Henry rifle, 16 shot, 44 cal., cost $40, in good order, or one double barrel shot gun, barrels London fine twist, or offers. J. B. Garrison, Belton, Bell Co., Texas.

What offers for "The Chefs D'Oeuvre D'Art, Paris Exhibition 1878," cost $16, good as new, bound; 1 large photo camera, complete, cost $95; Scientific American from 1859 to 1880, 4 vols. bound. D. Keesler, Stony Point, N. Y.

Sea shells of Atlantic coast, scientifically marked, for books, old or new magazines, Indian relics, natural history specimens, apparatus; anything. Wilfred Leon Miller, P. O. Box 392, Cape May, N. J.

A dulcimer that cost $20, books and fossils, for a telescope, microscope, fossils, Indian relics, or offers. E. J. Votaw, Salem, Iowa.

A self-inking model press, 5 x 7½, cost $23; $90 worth of scroll-saw designs in lots to suit; Scientific American, 1880; Palliser's Useful Details, $3; for photo outfit or offers. C. H. Parker, Coldbrook Springs, Mass.

Telegraph key and sounder, Frank Leslie's Illustrated Magazines, mounted microscopic objects, natural curiosities, for bull's-eye condenser, photograph camera, Unabridged Webster Dictionary, or offers. W. T. Alan, Greenville, Mercer Co., Pa.

Large magic lantern, spectroscope, pantagraph, for enlarging drawings, rosewood writing desk, man's saddle, for microscope, photo outfit or offers. Thomas Walters, Bergen St., East of Brooklyn Ave., Brooklyn, N. Y.

Model card press, chase 3¼ x 5¼, with 4 fonts type, cases, etc., for good foot lathe. Mills Day, 2 Farmington Av., Hartford, Ct.

French microscope, inclines to any angle, delicate fine motion, neat upright case, cost $17.50, for scientific books; send list to W. Fitz, P.O. Box 2852, New York.

Wanted, Quinby's New Bee Keeping, for Our Own Birds of the United States, by W. S. Baily; new. Joseph Anthony, Jr., Coleta, Whiteside Co., Illinois.

Printing type, small pica; large and small capitals, and small letters; 60 to 65 lbs., including two large cases; also gothic nonpariel, for trade. J. Siler, 1242 Broadway, St. Louis, Mo.

One years' copy of Aldine, cost $5.50, and German accordion, with instructions how to use it, cost $5.00, for offers. Chas. Dempwolf, 86 Benson St., Paterson, N. J.

A Novelty printing press, with type, prints a form 5 x 7 inches, cost $40.00, for a microscope, photographic apparatus, or offers. T. W. Patterson, Warsaw, N. Y.

$80 worth of (nearly new) printing material, minerals, fossils, Aboriginal relics, etc., for scientific books, good American watch, and offers. F. M. Farrell, Cobden, Union Co., Ills.

Rocks, minerals, fossils and fresh water shells for microscope stand, $20 to $75, also for objectives, turning lathe type, and tools. D. D. Babcock, South Dansville, N. Y.

Mechanical Electricity, Medical Chemistry, by Robert Hare; Fruits and Farinacea, by Trall; Complete Herbalist, by O. P. Brown; for mounted objects for the microscope or offers. J. B. Playter, Bristow, Butler Co., Iowa.

Violin (cost $10) and 5-shot 32-cal. revolver (cost $4), for photo-camera lens and tube, watch, parlor rifle, extra well-bred canary birds, or offers. C. Maides, St. Louis, Mo.

To exchange for a wood-turning lathe or offers, a Young America Self-inking Printing Press, with type and outfit complete; chase 3 x 5 inches. Embury McLean, 318 Bloomfield St., Hoboken, N. J.

What offers for "Our First Century," cost $7.00, bound in sheep, over 400 illustrations, 1,000 pages; also small Ruby Magic Lantern, cost $1.50. Box 217, So. Manchester, Conn.

Magic lantern, in good order, condensing lens, 2½ in. diameter, 8 slides. For small photographic camera or offers. H. A. Giddings, 4 Union Place, Classon Ave., Brooklyn.

Printing press, type, etc., worth $13, for offers. E. G. Vogeley, 1010 Bradford St., Pittsburgh, Pa.

Fifty canary birds, with and without crests; fancy poultry, conch shells, strombus alatus. For small printing press, books on natural history, or offers. Frank Lattin, Gaines, N. Y.

A good plain 7 shot revolver, 22 calibre, for a Students' inch or half-inch objective. Frank F. Colwell, Urbana, Ohio.

Wanted, Printing press and type, in good order, chase 6 x 10, or larger; will give hardware, tools, scroll saw, or designs. Chas. E. Little, 59 Fulton St., New York.

Photo outfit, tools, chemicals and apparatus, etc., etc.; wanted scientific books, apparatus, etc.; send lists. A. B. Campbell, Box 59, South Dayton, Catt. Co., N. Y.

Pens.—For pens for mercantile purposes the tendency is to use those with blunt points, leaving the extra fine and elastic for schools and professional penmen. For correspondence and rapid writing pens are enquired for that will make a distinct and bold outline without regard to shading, such as Esterbrook's Nos. 122, 183, and 1743, all having blunt points. Those with turned up points are especially suitable for the same purposes, and have a remarkable easy, quill-like action, represented by Esterbrook's Nos. 1876, 256, and 309.

Preference is given by many to the short nib or stub pens, of which the Nos. 161 (Engrossing), and 284 (Blackstone), of the same make, are the most popular.

The Young Scientist

SCIENCE IS KNOWLEDGE. KNOWLEDGE IS POWER.

A PRACTICAL JOURNAL OF

HOME ARTS

VOL. V. NEW YORK, MAY, 1882. No. 5.

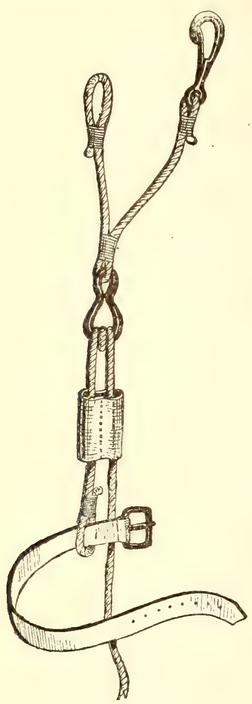
A Simple Fire Escape.

EVERY time a great fire occurs in a tall building we find either actual loss of life, or cases in which some of the occupants had a very narrow escape. It would seem that the ordinary fire escapes soon become useless, and at many of our great fires the ladders used by the firemen are entirely too short to reach the upper stories. This was notably the case at the fire in Park Row last winter (the old "World" building), where even such a well equipped establishment as the New York Fire Department had not within their command the means of reaching the upper stories of a building of comparatively moderate height. As a consequence of this state of things, numerous costly and complicated fire escapes have been invented, but the difficulty is that they are never at hand when wanted. Others have recommended the use of a simple rope, three-eighths of an inch in diameter, and knotted at intervals of fifteen inches. Such a cord, made fast to a staple or bar, would enable an active man to descend from any story, provided he did not become giddy, and his hands were not too soft. Men whose occupation is writing could hardly descend by means of such a rope. Neither could women. But by taking advantage of the great friction to which even a single turn of a rope round a rod gives rise, it is easy for even a weak woman to let herself down safely. But of course the rope must be secured to the body in such a way that its holds does not depend upon the strength of the person using it.

The simplest and most efficient arrangement is that shown in the engraving. First of all, we have, at the upper end, a short rope fastened to the eye of an iron link. This rope has a loop at one end, and a snap at the other, so that it can be fastened in a moment to the leg of a bedstead, to a staple, or to any other strong hold. The lower eye of the iron ring

is made larger, so that the main rope may go round it twice, and the two ends of this rope pass through a sleeve of light leather or heavy duck, so as to prevent entanglement. One end of the main rope has a loop through which passes a stout leather belt, long enough to go round the waist of any person; the other end is free.

When in use, the upper rope is fastened securely to the building, or to any heavy object that cannot be dragged through a window; the belt is then fastened round the waist, and the person who is to descend draws the other end of the rope



A SIMPLE FIRE ESCAPE.

tight, and holding it firmly in the hand, steps off the window sill. By easing the end of the rope that is held in the hand, we may lower ourselves as rapidly as may be desired, while at the same time a strain of a few ounces will create enough friction to support the heaviest individual.

Such a fire escape may first be used by the men to lower all women and children, and afterwards the men may descend one by one. It is so cheap and simple that any person can procure one, and it can never fail or get out of order.

Practical Hints on the Construction of the Violin—II.

LET us now suppose the materials from which we are to construct our violin to have undergone the necessary seasoning and drying process. The next thing to be done is to provide ourselves with tools. The amateur violin-maker will find this one of the most discouraging obstacles to be overcome. He will search hardware stores and tool-makers' shops in vain, and in the end will find himself under the necessity of making most of the implements he needs. We will endeavor, as we go along, to give an idea of the requisite tools, but in the absence of proper drawings, the description must necessarily be very incomplete.

We shall commence with the back or under table of the instrument. Two of the wedge-shaped pieces of maple are dressed down neatly with the plane, and then clamped firmly in the vice with their thick edges together as they grew. The thick edges are then planed down and neatly jointed. For this purpose the plane must be very sharp and accurate, or else it will be found impossible to make a good joint. When the joint is absolutely perfect, the pieces are slightly warmed, one of them is clamped in the vice, the surfaces to be joined covered with good, rather thin and hot glue, and rubbed one on the other until the glue begins to set. If the pieces rock or swim during the rubbing, it is an evidence of bad jointing, and they must be separated, the glue cleaned off with a little warm water, and a new joint made. If the joint be good the parts are allowed to remain in the vice until well set, and then put away in a dry place for at least twenty-four hours. In no case should they be clamped together, as a joint thus made is always liable to open and leave an unseemly line down the centre of the back. The two pieces which compose the belly of the instrument must be treated in the same manner as those for the back, but being

of spruce, the work of making a good joint will be found much easier.

The next operation is to prepare the sides, sidê-linings, corner and end blocks. The sides must be of the same material as the back. They are first sawn into strips about fourteen inches long, an inch and a quarter wide, and about a sixteenth of an inch thick. The side-linings are of spruce, about the same length as the pieces for the sides, a quarter of an inch wide and an eighth thick. The end blocks and corners are also of spruce; the end blocks are semicircular and of the same height as the sides; the corners when finished are almost triangular.

The next thing to be done is to lay out the shape of the instrument, and as a great deal of the tone of the violin depends on its shape, it is necessary that this part of the work be done with extreme care. The best plan for the beginner would be to select a good instrument and make his model accordingly. Having made his selection, he draws on cardboard an exact figure of the inside of the instrument he desires to copy, omitting the corners, so that the figure drawn may resemble a guitar.

This pattern he places on a plank of good hard wood about inch and a half thick, and somewhat larger than the body of his intended violin, and with a sharp pencil draws thereon the outline by closely following the cardboard pattern. He then, with a good scroll-saw, cuts out from the block a mould on which to build his instrument. If the sawing has not been well done it may be necessary to go over the work with a file until the edges are perfectly straight and the form symmetrical. The mould is then planed down to the height the sides are to be, slanting it towards the narrow or neck end until the difference is about a sixteenth of an inch. A semicircular piece is then cut out from the neck end, and another from the opposite end where the neck and tail-blocks are to be, and four small mortise-like recesses about an inch by a quarter of an inch, where the corner blocks are to be placed.

A mortise about two inches long and an inch and a half wide must now be made in the centre of the mould, and from this mortise two wedge-shaped blocks are sawn out, running lengthwise to where the neck and tail-blocks are to be. The beginner will remember that the mould was sawn from a large plank. Let him now take this plank and extend the opening from which he cut his mould about an inch all around. This will serve as a clamp when he comes to set up the sides.

It will be remembered that the mould was sawn into four pieces. These pieces must be clamped together in the following manner: Take two plates of steel and drill five holes in each, large enough to admit inch wood screws with round heads—two near each end of the plate and one in the centre. The sections of the mould should then be placed together just as they were before being separated by sawing. Mark the holes with a pencil, drill the wood to receive the screws, and screw fast. The mould is now ready for the end and corner blocks. Before inserting the blocks, the recesses should be covered with paper, which may be attached with a little glue. The blocks are then neatly fitted to the recesses and glued. When this has been done the mould is ready for the reception of the sides. The sides should be boiled in water and then bent on a hot iron into shape. Then having neatly trimmed the sides and shaved off the ends where they meet on the corner blocks, and having trimmed down the blocks to their proper shape, insert the "D" pieces, one on each side of the mould, and glue to the corner blocks. In the meantime the mould and frame should both be screwed fast to a board placed underneath, so that the sides may be held fast to the blocks by means of wedges pressed down between the mould and frame. When the "D" pieces have set, the other side pieces may be glued in their place, taking care to make a neat close joint where they meet at the larger or tail-piece end of the mould. There is no need of making a close joint at the other end, as part of the sides and block must be afterwards cut away for the reception of the neck.

The next operation is the making of the back and belly of the instrument, and as

this is the most important operation in violin making, we will reserve our remarks on it for a future essay.

(To be continued.)

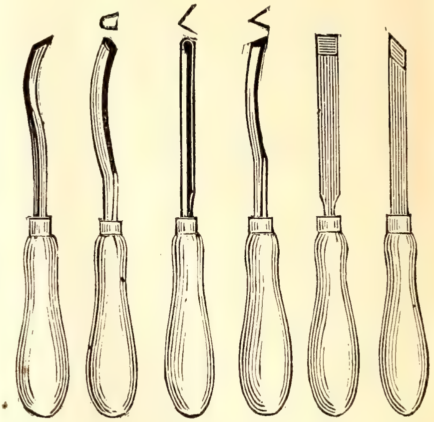
Amateur Wood Carving.

BY FRED. T. HODGSON.

TO the amateur woodworker who has never tried a hand at *wood carving*, the beautiful art seems so full of difficulties and mystery that it is rarely essayed by any but the most expert and advanced amateur workman. There is no reason why any person, who has sufficient judgment to keep edge tools in moderate order should not be able to become a fair amateur carver. Of course, no person, no matter how clever he or she may be, can reasonably expect to do even indifferent work, at the first attempt; there is no royal way by which the inexperienced may be made an adept in the art at one stroke. There is one thing, however, that is very clear to any person who knows any thing about wood-carving, and that is, that any boy who is able to write his own name in a legible manner, possesses artistic and mechanical talent enough to make an average amateur wood carver. The same thing may be said of girls, and in fact, it may be said, that as a rule, girls make finer work in this art—up to a certain point—than boys. This being the case then, there is no reason why our young friends—boys and girls alike—should not try their hands at this fascinating art, and to aid them in their efforts the following hints, suggestions and examples are offered:

The first thing to be considered is the selection of tools, and with regard to this matter let it be understood right here, that to do good work it is absolutely necessary that the appliances for doing the work must be good also. A good workman cannot make good work with bad tools; an indifferent workman may make good work if possessed of good tools.

The best carving tools are made by Addis, and although costly at first, are, in the end, cheaper than many makes now in the market. A set of nine tools suitable for amateur work would cost about six dollars, and where the magnitude of this sum is no objection, the purchase of these tools is advisible. Where this sum is too large, however, a set of amateur carving tools might be obtained, such as we show in Fig. 1. Here are six tools, and



1 2 3 4 5 6

Fig. 1.

are so made, when of good material and temper, that almost any ordinary amateur work may be executed with them. They are sold in sets just as exhibited, put up in neat boxes for from $1.10 to $1.50. The three principal tools in the set are the flat chisel (5), the gouge (3), and the veining tool (4). To use these properly requires some little practice, and the learner should begin first by securing a pine or white-wood block to his bench by screws or glue. The block should be about seven inches long, four inches wide, and one inch thick. Having the block all prepared and the tools in good order, the next step should be to prepare some simple design that may be easily worked. The one shown at Fig. 2 is well adapted to our purpose, as it embodies two kinds of work—*i.e.*, carving and punching. The light colored spaces show the raised parts, and the dotted ones the sunken parts. The dark lines on the outside edge show a bevel all round. This is made with the flat chisel, and should be carried down the edges about three-eighths of an inch, and five-eighths of an inch on the top of the block. The mitres at the corners must be true

and perfect or the work will look slovenly finished. The raised parts of the example before us stand out in relief about one-eighth of an inch, and must be finished

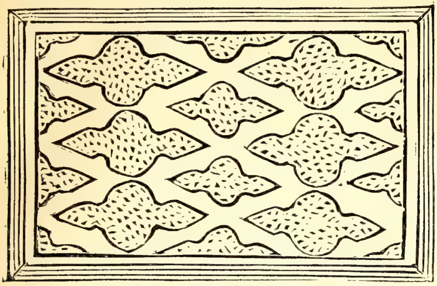


Fig. 2.

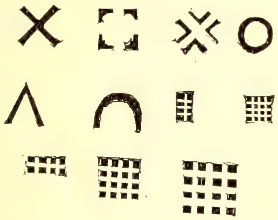
smoothly on the edges. The dotted work is formed by a series of little punches, a number of which are shown at Fig. 3, each



1

Fig. 3.

pattern of which may be obtained at any well furnished hardware store for about twenty-five cents. No. 1 is the pattern required for the example.

To line off the raised work, take the V or parting tool, hold it in your right hand at a proper cutting angle, put your left wrist on the wood to be operated on, pass your hand over the steel, the thumb underneath, and the tips of the fingers resting on the work. This will give you perfect command of the tool; will prevent its slipping forward; enable you to guide it round the curves, and the thumb being under the tool, you can grasp it at any moment with the whole hand. Be careful and do not cut in too deep with this tool. When the pattern is well marked in the block with this tool, then the flat chisel may be used to advantage. In punching, be careful and strike short sharp strokes on the punch with a hammer, and in such a manner that each blow will have a like effect with all others on the same work. Turn the punch after each blow, so as not to give the grounding a liney or uniform appearance; and one more caution, if you see that the punch raises little chips of wood, try the other way of the grain, or turn the punch so that it will not raise the chips. A little practice with these punches will soon enable the operator to do very nice work of this sort.

This kind of carving is called diaper carving, and is very effective when properly executed.

The example shown at Fig. 2, when finished, would make a very nice lid or cover for a box, and if ends and front were executed in the same manner without beveling the edges, a very nice box for gloves, cuffs or collars might be constructed with them.

This is a very simple lesson in carving, and if the young beginner should fail in this, the first attempt, it will be no discredit, providing it does not discourage, for it must be borne in mind that most of our best carvers have not arrived at their present state of perfection without having first spoiled many a piece of good stuff. If the first attempt should prove a failure, do not be discouraged, but turn the block over and try the same pattern on the other side; be more careful this time, and success will surely crown your efforts if you will only persist.

Fig. 4 shows an escutcheon which is finished on the same principle as Fig. 2. There is a raised border all round the edge, and a few sprays on the surface are

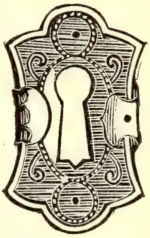


Fig. 4.

raised, the sunken part is diapered with one of the punches shown in Fig. 3. This is made of hard wood and only about a quarter of an inch thick.

Fig. 5 represents a rosette ornament, or

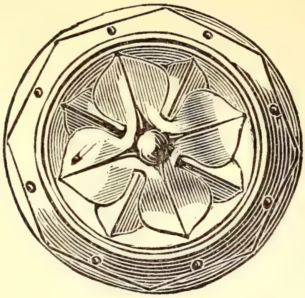

Fig. 5.

it would do very well for the end of a drawer knob. This is a very simple piece of carving in relief, and will not tax the skill of the operator very much. It is so simple that explanation is unnecessary.

The beginner must remember one thing, and that is, never to use sandpaper on carved work. All lines and angles should be left sharp and well defined, and this feature cannot exist if sandpaper is used on the work, as it will most assuredly destroy it.

We have now said sufficient to give the beginner a fair start in the art of carving, and we hope he will continue to practice it until he becomes ambitious to try his skill on something more difficult, when we will, in a future chapter, be pleased to give him further aid.

A DRIVE.

BY MARY H. WHEELER.

Up from her cavern a water-sprite came
For a drive on the moonlighted lake,
And her transparent garments, all bright as a flame,
Left a luminous trail in her wake.

Her car was a diatom, shapely and strong,
Which shone iridescent in gleam,
And with bands of conferva she guided along
Her tandem-hitched rotifer team.

As, rearing and plunging, her steeds with a dash
Went rapidly circling by,
Through the sparkling water she went like a flash
Of electrical light from the sky.

The Daphnia held up her hands in surprise,
"My eye!" cried the Cyclops, "that's gay!"
And the Hydrachna winked with her two pairs of eyes,
While the Cypris went swimming away.

But alas for this turnout so jaunty and nice!
When the moon marked the full midnight hour,
A trout gobbled up the whole team in a trice,
And the water-sprite fled to her bower!

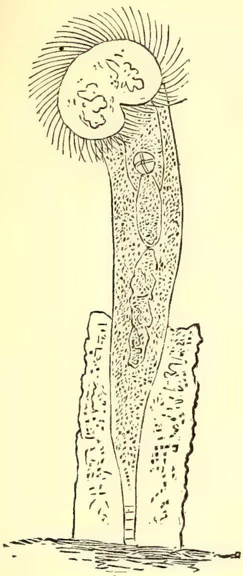
Pittsfield, N. H.

Marvels of Pond Life.—IX.

As usual the Kentish Town ponds were productive of objects, and among them were several rotifers not found previously. The first of these was a very small worm-like thing, with one eye, a tuft of cilia about the mouth, and two toes at the tail end. Had it not been for the jaws, which were working like fingers thrust against each other, and which were unmistakably of the Rotifer pattern, the animal might have been supposed to belong to some other class. According to the "Micrographic Dictionary," the *Lindia torulosa* is 1-75″ long, but this specimen was only about 1-200″. It was possibly very young, and did not thrust out its cilia in two distinct tufts, as Cohn describes, although it may have had the power of doing so. At times it sprang quickly backwards and forwards, bringing its head where its tail was before. This object required for its comfortable elucidation a power of about six hundred linear.

Among the common water plants, which are worth examining as the probable abodes of rotifers or infusoria, is the pretty little thing called "star-weed," some of which was obtained from the last-mentioned ponds, and on examination yielded a specimen of a tube-dwell-

ing rotifer, the *Œcistes crystallinus*, which, although less beautiful than the Floscules or the Melicerta, is, nevertheless, a pretty and interesting object. In this instance a little rough dirty tube, about 1-70″ long, was observed to contain an animal capable of rising up and expanding a round mouth garnished with a wreath of cilia; while a little below, the indefatigable and characteristic gizzard

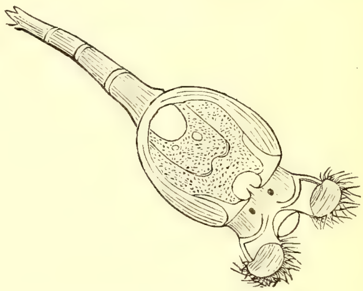


Œcistes crystallinus. × 240.

of the tribe was in full play. A power of two hundred and forty linear sufficed to afford a good view, and it was seen that a long, irregular, conical body was supported upon a short wrinkled stalk. The usual drawings represent this creature with a short bell-shaped body upon a very long slender pedicle. Possibly this one might have been able to show himself under this guise, but he did not attempt it; his appearance being always pretty much as described, which made the foot shorter and the body longer than the measurements which naturalists have given, and according to which the whole creature is 1-36″ long, although the body is only 1-140″. The tube of the *Œcistes* is called a "lorica," or carapace; but it has in truth no right whatever to the appellation.

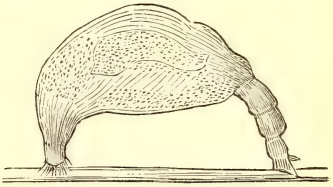
Another strange rotifer, of whose name I am uncertain, had an ovalish oblong body, and a pair of legs like compasses, twice as long as himself. His antics were those of a posture-master, or "Professor of Deportment" on stilts. Sometimes he stood bolt upright, bringing his legs close together; then they were jauntily crossed, and the body carried horizontally; then the two legs would be slightly opened, and the body thrown exactly at right angles to them. These antics were repeated all the while the observation lasted, and had a very funny effect in proving that drollery is practiced, if not understood, in the rotatorial world.

Another kind of rotifer was abundant—the *Philodina*, which belongs to the same family as the common wheel-bearer, namely, the *Philodinœa*. The *Philodina* is a good deal like the common wheel-bearer, or *Rotifer vulgaris*, but is usually of a stouter build, and carries his eyes in



Philodina (swimming).

a different place. In the common rotifer these organs are situated on the proboscis, while those of the Philodina are lower, and said to be "cervical." The changes of form in this rotifer are still more remarkable than in the common wheel-bearer. When resting it resembles a pear-shaped purse, puckered in at the mouth. Then it thrusts out its tail-foot, swells its body to an oval globe, protrudes its feeler, and slightly exposes a row of cilia. After this two distinct wheels are everted, and as their cilia whirl and spin, the animal is swiftly rowed along, until it thinks proper to moor itself fast by the tail-foot, and employ all its ciliary power in causing currents to converge towards its throat. When it pleases it can elongate the body, till it becomes vermiform, and it walks like the common rotifer, by curving its back, and bringing its nose and its tail in contact with the ground.



Philodina (crawling).

The gizzard of this family (*Philodinœa*) presents a considerable deviation from the perfect form exhibited by the *Brachions*. According to Mr. Gosse, "The *mallei* and the *incus* (terms already explained) are soldered together into two subquadrantic-globular masses, which appear to be muscular, but invested with a solid integument. The *manubria* (handles) may still be recognized in a vertical aspect as three loops, of which the central one is chiefly developed, and in a vertical aspect as a translucent reniform (kidney-shaped) globe." These descriptions are not easy to understand, not from any want of clearness or precision in the words employed, but from the complicated character of the organ, and its very different appearance under different aspects. To make the matter more intelligible, Mr. Gosse adds, "the structure and action of an apparatus of this type may be made more clear by a homely illustration. Suppose an apple to be divided longitudinally, leaving the stalk attached to one half. Let this now be split again longitudinally so far as the stalk, but not actually separating either portion from it. Draw the two portions slightly apart, and lay them down on their rounded surfaces. They now represent the quadrantic masses in repose, the stalk being the fulcrum, and the upper surfaces being crossed by the teeth. By the contraction of the muscles, of which they are composed, the two segments are made to turn upon their long axis, until the points of the teeth are brought into contact, and the toothed surfaces rise and approach each other. The lower edges do not, however, separate as the upper edges approach, but the form of the mass alters, becoming more lenticular, so that when the toothed surfaces are brought into their closest approximation, the outline has a subcircular figure. It is on account of this change of form that I presume the masses themselves to be partially composed of muscle."

These remarks, although specially made of the *Rotifer macrurus*, are in the main applicable to all the Philodinas, but the student must not expect to understand any of the complicated gizzards of the rotifers without repeated observations, and no small exercise of patience. It is common to call the portions of the Philodine-pattern gizzard "stirrup-shaped," but Mr. Gosse has shown them to be *quadrantic*, that is, shaped like the quarter of a sphere.

As we are not very well off with subjects for description at present, we can afford a little time to consider a question that continually arises in the mind on viewing the movements of animalcules, and especially of any so highly developed as the rotifers, namely, to what extent motions which appear intelligent are really the result of anything like a conscious purpose or will. When any of the lower animals—a bee, for example—acts in precisely the same way as all bees have acted since their proceedings have been observed, we settle the question by the use of the term *instinct*. Those who take the lowest view of insect life, assume that the bee flies because it has wings, but without wishing to use them, and that the nerves exciting them to action are in their turn excited, not by volition, but by some physical stimulus.

The sight or the smell of flowers is thought by the same reasoners to be capable of attracting the insect, which is unconscious of the attraction, while proximity of food stimulates the tongue to make the movements needful for its acquisition, and so forth. The cells, they tell us, are built according to a pattern which the earliest bee was impelled to construct by forces that bear no analogy to human reason and human will, and so originate all the ordinary processes of bee life. Sometimes, however, it happens that man or accident interposes particular obstacles, and forthwith there appears a particular modification of the orthodox plan, calculated to meet the special difficulty. How is this? Does any one of the difficulties which the bee or the ant is able to get over, produce precisely that kind of electrical disturbance, or polar arrangement of nerve particles that is necessary to stimulate the *first* step of the action by which the difficulty is surmounted; and does the new condition thus established stimulate the *second* step, and so forth, or can the bee, within certain limits, really *think*, design, and contrive?

No questions are more difficult of solution; but while protesting against a tendency to undervalue all life below that of man, we must remember we have in our bodies processes going on which are not the result of volition, as when the blood circulates, and its particles arrange themselves in the pattern required to form our tissues and organs, and also that many of our actions belong to the class termed by physiologists, "reflex," that is, the result of external impressions upon the nervous system, in which the *sentient* brain takes no part. Thus when a strong light stimulates the optic nerve, the portion of brain with which it is connected in its turn stimulates the iris to contract the pupil; and it is supposed that after a man has begun to walk, through the exercise of his will, he may continue to walk, by a reflex action; as his feet press the ground they transmit an impression to the spinal cord, and the legs receive a fresh impulse to locomotion, although the mind is completely oc-

cupied with other business, and pays no attention to their proceedings.* The ordinary movements of insects appear to be of this character, and to be excited by the ganglia belonging to the segment to which the moving limbs are attached. Thus a centipede will run, after its head has been cut off, and a water-beetle (*Dytiscus*) swam energetically when thrown into water after its brain has been removed.†

It must not, however, be assumed that the brain of insects has nothing to do with their movements. It is probably the means of co-ordinating or directing them to a common end, and gives rise to what are called *consensual* movements, that is, movements which are accompanied or stimulated by a sensation, although not controlled by a will. In man these actions are frequently exhibited, "as when laughter is provoked by some ludicrous sight or sound, or by the remembrance of such at an unseasonable hour."‡ Sneezing is another instance of a sensation leading to certain motions, without any intervention of the human will.

Speaking of these consensual motions, Dr. Carpenter observes, "It is probable, from the strong manifestations of emotion, exhibited by many of the lower animals, that some of the actions which we assemble under the general designation of instinctive are to be referred to this group."

The insect brain is composed of a supra-œsophagal ganglion and infra-œsophagal one. Von Siebold says, the first corresponds to the cerebrum of the vertebrata, and "the second is comparable, perhaps, to the cerebellum or spinal cord."§ The superior ganglion gives off nerves to the antennæ and eyes, the lower one to the mandibles, etc. So far as is known the insects that exhibit the most intelligence have the largest and best developed brains.

A special volume would be required for anything like a complete examination of the little which is known on this subject, but these few remarks may assist the microscopic beginner in examining the movements of his subjects, and guard against the error of referring to reason and volition those which are probably, either the direct result of stimulants applied to the surface (as in nerveless creatures), or the indirect (reflex) result of such stimulants in beings like the rotifers, who have a nervous system; or the result of *sensations*, which excite actions without previously referring the matter to the decision of a will. It must not, however, be too readily assumed that the behavior of creatures possessing distinct organs is entirely automatic; and we must not forget that even the best physiologists know very little concerning the range of functions which the nervous ganglia of the invertebrata are able to discharge.

Astronomy for Amateurs.

BY BERLIN H. WRIGHT.

(All calculations are for the Latitude and Meridian of New York City.)

THE PLANETS FOR MAY, 1882.

MERCURY may be seen during the last few days of May and the first of June as an evening star setting as follows:

May 26,	9h.	12m.,	evening.
" 30,	9	14	"
June 3,	9	13	"

He may be seen about 5° north of the sunset point. Venus and Mercury approach very closely on the 29th and 30th. Venus being distinguishable by her superior apparent diameter, milder light and by being south of Mercury; separated, however, by less than 2°. This will be an interesting occurrence to witness, which none should fail to see.

VENUS is rapidly receding from the Sun and moving eastward past the fixed stars. At the beginning of the month she is in the eastern part of Aries and between the Pleiades and Hyades, and on the 5th she passes Jupiter, being when nearest, about one degree north of him. Then passing over several degrees she enters the milky way. About the 20th and on the 29th she passes Mercury and proceeds eastward into Gemini. She will be about 15° S.W. of Castor and Pollux on the 30th.

She sets as follows:

May 10,	8h.	39m.,	even.
" 20,	9	1	"
" 30,	9	19	"

MARS is about 20° east of Venus and in the Constellation Cancer. He is in the group Prœsepe on the 18th, and 6° north of the Moon on the 22d. He sets as follows:

May 10th,	0h.	26m.,	morning.
" 20	11	59	evening.
" 30	11	36	"

JUPITER is too near the Sun to be successfully observed, being in conjunction with the Sun on the 30th.

SATURN, too, is invisible, being in conjunction with the Sun on the 6th, as is also Neptune.

TOTAL ECLIPSE OF THE SUN.

The Sun will be totally eclipsed on the 17th. This eclipse is visible throughout all of the

Eastern Continent, except the southern point of Africa. The line of totality passes through Shanghai and Nanking in China, Bagdad and Alcaba, and terminating near the west coast of Africa in 11° north lat. It is stated that Prof. Swift, of Rochester, N. Y., will be in Arabia to make search for the intra mercurial planets which he believes he has seen. Certainly if he does not meet with success in the pure dry atmosphere of Northern Arabia, further effort in that direction would seem useless.

APPEARANCE OF THE HEAVENS AT 9 P.M., MAY 20, 1882.

Looking southward the beautiful star Spica Virginis is very near the meridian and only 3° south or below the earth's path (Sun's apparent path). To the left of this star is the quadrilateral in Libra. Arcturus is about an hour east of the meridian and the large cluster of small stars called Berenice's Hair is almost overhead. The Sickle and Regulus in Leo are nearly half way to the western horizon, and still west of them is Mars in Cancer. Procyon is near setting. Castor and Pollux are higher up and further north, and Venus is west of them a few degrees.

In the east, Altair in the Eagle has just risen in the N.E., and Scorpio and Antares in the S.E.

Looking northward, the Great Dipper in Ursa Major is just north of our zenith; the head of Draco is to the right of Polaris, and Cassipeia's Chair below and close to the northern horizon. Algenib in the bright cluster in Perseus is just west of the lower meridian and near the horizon.

EPHEMERIDES OF THE PRINCIPAL STARS AND CLUSTERS, MAY 21, 1882.

	H.	M.	
Alpha Andromedæ (Alpheratz) rises	0	8	morn
Omicron Ceti (Mira) variable, rises	4	26	"
Beta Persei (Algol) variable, rises	1	52	"
Eta Tauri (Alcyone or Light of Pleiades) rises	4	12	"
Alpha Tauri (Aldebaran) invisible			
Alpha Aurigae (Capella) sets	11	14	even
Beta Orionis (Rigel) invisible			
Alpha Orionis (Betelguese) sets	8	12	"
Alpha Canis Majoris (Sirius or Dog Star) invisible			
Alpha Canis Minoris (Procyon) sets	9	49	"
Alpha Leonis (Regulus) sets	0	47	morn
Alpha Virginis (Spica) in merid.	9	16	even
Alpha Bootis (Arcturus) " "	10	7	"
Alpha Scorpionis (Antares) " "	0	23	morn
Alpha Lyrae (Vega) " "	2	33	"
Alpha Aquillae (Altair) rises	9	13	even
Alpha Cygni (Deneb) in merid.	4	37	morn
Alpha Pisces Australis (Formalhaut) rises	2	52	"

THE MOON, THIRD QUADRANT, CONCLUDED.

Very near the southern limb of the Moon lies the deepest of the Lunar Craters—Newton (256). This is exceedingly irregular in outline, being about 142 miles long and 70 broad. Several lofty towers surmount the wall, the highest of which is 24,000 feet above the interior. There is only one small crater between this and the Moon's lower limb, where a series of colossal mountains stand out in bold relief, and are bathed in perpetual sunlight. The Moon's axis is inclined only about 1½° to her orbit, hence such mountains as are on or near the Arctic or Antarctic circle, as we apply those terms to the earth, are never in darkness. On each side of the South Pole and extending into both the 3d and 4th quadrants lie lofty peaks that project beyond the limb and break its continuity. Several of these measure nearly 30,000 feet, and one author announces 36,000 feet as the height of one. When the Moon is reduced to a delicate crescent near the new, these mountains prolong the horn. Just to the left and above Newton is an attractive crater (260) 51 miles in diameter and bearing a peak 18,000 feet above the interior. Almost touching the last is another, larger and steeper, and from its flat interior ten craterlets lift their heads.

In a direct line with the last two named craters and separated from 260 by its own diameter only, is another (265) very deep crater with a towering peak 20,000 feet high. Almost touching 265 upon the west is an interesting ring 78 miles broad and of very unequal height. It is 15,000 feet high on the west side and terraced within. This crater contains the highest central peak yet measured—6,800 feet. When the Sun rises or sets upon its peak it may be seen as a golden spot in the dark shadow of the surrounding wall. Look for it about one day after first quarter.

The numbering now carries us over to the East limb, where the naked eye detects a long black spot; this (272) crater has a darker interior than any other of its size. It is 147 miles long and 129 wide. A trifle east and extending far south of this great black crater is a series of ranges 20,000 or more feet high. Some of these may be seen projecting from the eastern limb. About 15° south of these seems to be a continuation of the same range projecting from the Moon's limb also—these are called the Rook Mountains.

WELLS' COMET, 1882.

Mr. S. C. Wells, Assistant at Dudley Observatory, at Albany, N. Y., discovered a comet of much prominence March 18.

From *The Science Observer*, of Boston, a periodical devoted to original astronomical work, we glean the following information: During the latter part of May the comet will be seen low in the N.W., with the bright star Capella 15° to the left.

Director Boss says of the comet: "It is evident that the comet should have a brilliant career; its light at perihelion (June 1) should be more than three thousand times greater than at discovery. I believe that the comet has a large and active nucleus, and if this be true, we ought to see a tail of immense proportions in June." This comet was unusually bright at discovery, considering its distance from the Sun, and its elements are very different from known comets.

Penn Yan, Yates Co., N. Y.

Silvering Iron.

A manufacturer in Vienna employs the following process for silvering iron: He first covers the iron with mercury, and silvers by the galvanic process. By heating to 300° C., the mercury evaporates and the silver layer is fixed. Ironware is first heated with diluted hydrochloric acid, and then dipped in a solution of nitrate of mercury, being at the same time in communication with the zinc pole of an electric battery, a piece of gas carbon or platinum being used as an anode for the other pole. The metal is soon covered with a layer of quicksilver, is then taken out and well washed and silvered in a silver solution. To save silver the ware can be first covered with a layer of tin; one part of cream of tartar is dissolved in eight parts of boiling water, and one or more tin anodes are joined with the carbon pole of a Bunsen element. The zinc pole communicates with a well cleaned piece of copper, and the battery is made to act till enough tin has deposited on the copper, when this is taken out and the ironware put in its place. The ware thus covered with tin chemically pure and silvered is much cheaper than any other silvered metals.

Writing with Lemon-juice.

Father John Gerard, of the Society of Jesus, who was confined and cruelly tortured in the Tower of London at the end of Queen Elizabeth's reign, was in the habit of writing letters in orange or lemon juice to his friends. The manner in which he thus baffled the vigilance of his jailers is described in detail in his highly interesting autobiography, published a few years ago by the Rev. Father John Morris. Father Gerard says:

"Now lemon-juice has this property, that what is written in it can be read in water quite as well as by fire, and when the paper is dried the writing disappears again till it is steeped afresh, or again held to the fire. But anything written with orange-juice is at once washed out by water and cannot be read at all in that way; and if held to the fire, though the characters are thus made to appear, they will not disappear; so that a letter of this sort, once read, can never be delivered to any one as if it had not been read. The party will see at once that it has been read, and will certainly refuse and disown it if it should contain anything dangerous."

One result of Father Gerard's orange-juice correspondence was that, with the aid of zealous friends outside, he effected his escape from the Tower in 1597. The last ten years of his life were spent in the English College at Rome, where he closed a long, arduous, and meritorious career on July 27, 1630, aged seventy-three.—*The Budget.*

To Clean Paint.

When paint is washed with any strong alkaline solution, such as soda or strong soap, the oil of the paint is liable to be changed to soap and the paint is seriously injured. To avoid this take some of the best whiting, and have ready some clean warm water and a piece of flannel, which dip into the water and squeeze nearly dry; then take up as much whiting as will adhere to it, apply it to the painted surface, when a little rubbing will quickly remove any dirt or grease stains. After this wash the part well with clean water, rubbing it dry with a soft chamois. Paint thus cleaned will look as well as when first put on, and the operation may be tried without fear of injury to the most delicate colors. It answers far better than the use of soap, and does not require more than one-half the time and labor. Another simple method is the following: Put a tablespoonful of aqua-ammonia in a quart of moderately hot water, dip in a flannel cloth and with this merely wipe over the surface of the woodwork. No rubbing is necessary. The first recipe is preferable, except where the paint is badly discolored.

A Scientific Joke.

A German newspaper some time ago related an amusing story of the famous scientist, Alexander von Humboldt, who took advantage of the exemption from duty of the covering of

articles free from duty, formerly the rule in France. In the year 1805 he and Gay-Lussac were in Paris, engaged in their experiments on the compression of air. The two scientists found themselves in need of a large number of glass tubes, and since this article was exceedingly dear in France at the time, and the duty on imported glass tubes was something alarming, Humboldt sent an order to Germany for the needed articles, giving directions that the manufacturer should seal the tubes at both ends, and put a label upon each with the words "*Deutsche Luft*" (German air). The air of Germany was an article upon which there was no duty, and the tubes were passed by the custom officers without any demand, arriving free of duty in the hands of the two experimenters.

EXCHANGES.

Only those who are *yearly* subscribers, and whose names are entered on our books have the privilege of inserting exchanges.

Exchanges must be on separate slips of paper or postal cards. If mixed with business matter in letters or cards they are filed away and never reach the printer.

Exchanges must not exceed thirty words.

Buying and selling belong to the advertising department.

We reserve the right to omit the exchange column, wher we have not room for it, and the amount of space at our disposal will regulate the number of insertions given to each *exchange*, the preference being always given to those who have not previously used our columns.

Blow-pipe set (cost $10), large illustrated family Bible (cost $7.50), for Wood's Botany, Dana's Geology, or printing press and type. H. W. Noble, Box 134, South Dansville, N. Y.

Wanted, offers for fossil shells from the west coast of Africa. A. W. Seward, 187 E. 71st St.

I have a number of birds' eggs I should like to trade for other birds' eggs; send for list of trading eggs. A. G. G., Box 26, Summit, New Jersey.

For a microscope stand or offers, a 36-inch turning lathe (new) and a number of scientific books; send for list. A. Kendall, Somerville, Mass.

Wanted services of amateur printer with small office (or large), in exchange for an interest in a well-established weekly paper, good size. Eagle Office, Plymouth, N. H.

American Agriculturist microscope, new, cost $15, for amateur photographic apparatus, lever watch, 22 calibre breech-loading sporting rifle or magic lantern of equal value. Wm. A. Walker, Rockland, R. I.

I. T. Bell, Franklin, Pa., has back numbers of Scientific American, Forest and Stream, and Young Scientist, good flute, chessmen, books, etc., for good magic lantern, revolver, scarce coins, or offers.

A steel spring bracket-saw, 2 doz. saw blades, and about 1 doz. patterns for a good stylographic pen or offers; send postal before exchanging. Geo. Oakley, Rutherford, N. J.

A rosewood banjo, 11 inch head, 12 nuts, fully strung, together with lot of dime banjo music and instructions, for microscope, Webster's Unabridged, monkey, squirrel and cage, or offers. J. DeWitt Clark, P. O. Box 37, Brooklyn, N. Y.

For self-inking printing press and type, one Henry rifle, 16 shot, 44 cal., cost $40, in good order, or one double barrel shot gun, barrels London fine twist, or offers. J. B. Garrison, Belton, Bell Co., Texas.

A new 40 diameter microscope, corals, and minerals, for a stylographic pen, air gun, or offers. J. McBride, 54 Garley St., Chicago.

What offers for "The Chefs D'Oeuvre D'Art, Paris Exhibition 1878," cost $16, good as new, bound; 1 large photo camera, complete, cost $95; Scientific American from 1859 to 1880, 4[illegible] vols. bound. D. Keesler, Stony Point, N. Y.

Sea shells of Atlantic coast, scientifically marked, for books, old or new magazines, Indian relics, natural history specimens, apparatus; anything. Wilfred Leon Miller, P. O. Box 392, Cape May, N. J.

A dulcimer that cost $20, books and fossils, for a telescope, microscope, fossils, Indian relics, or offers. E. J. Votaw, Salem, Iowa.

A self-inking model press, 5 x 7½, cost $23; $90 worth of scroll-saw designs in lots to suit; Scientific American, 1880; Palliser's Useful Details, $3; for photo outfit or offers. C. H. Parker, Coldbrook Springs, Mass.

Telegraph key and sounder, Frank Leslie's Illustrated Magazines, mounted microscopic objects, natural curiosities, for bull's-eye condenser, photograph camera, Unabridged Webster Dictionary, or offers. W. T. Alan, Greenville, Mercer Co., Pa.

Large magic lantern, spectroscope, pantagraph, for enlarging drawings, rosewood writing desk, man's saddle, for microscope, photo outfit or offers. Thomas Walters, Bergen St., East of Brooklyn Ave., Brooklyn, N. Y.

Model card press, chase 3¼ x 5¼, with 4 fonts type, cases, etc., for good foot lathe. Mills Day, 2 Farmington Av., Hartford, Ct.

French microscope, inclines to any angle, delicate fine motion, neat upright case, cost $17.50, for scientific books; send list to W. Fitz, P.O. Box 2852, New York.

Wanted, Quinby's New Bee Keeping, for Our Own Birds of the United States, by W. S. Baily; new. Joseph Anthony, Jr., Coleta, Whiteside Co., Illinois.

Printing type, small pica; large and small capitals, and small letters; 60 to 65 lbs., including two large cases; also gothic nonpariel, for trade. J. Siler, 1242 Broadway, St. Louis, Mo.

One years' copy of Aldine, cost $5.50, and German accordion, with instructions how to use it, cost $5.00, for offers. Chas. Dempwolf, 86 Benson St., Paterson, N. J.

A Novelty printing press, with type, prints a form 5 x 7 inches, cost $40.00, for a microscope, photographic apparatus, or offers. T. W. Patterson, Warsaw, N. Y.

$80 worth of (nearly new) printing material, minerals, fossils, Aboriginal relics, etc., for scientific books, good American watch, and offers. F. M. Farrell, Cobden, Union Co., Ills.

Rocks, minerals, fossils and fresh water shells for microscope stand, $20 to $75, also for objectives, turning lathe type, and tools. D. D. Babcock, South Dansville, N. Y.

Mechanical Electricity, Medical Chemistry, by Robert Hare; Fruits and Farinacea, by Trall; Complete Herbalist, by O. P. Brown; for mounted objects for the microscope or offers. J. B. Playter, Bristow, Butler Co., Iowa.

Violin (cost $10) and 5-shot 32-cal. revolver (cost $4), for photo-camera lens and tube, watch, parlor rifle, extra well-bred canary birds, or offers. C. Maides, St. Louis, Mo.

To exchange for a wood-turning lathe or offers, a Young America Self-inking Printing Press, with type and outfit complete; chase 3 x 5 inches. Embury McLean, 318 Bloomfield St., Hoboken, N. J.

What offers for "Our First Century," cost $7.00, bound in sheep, over 400 illustrations, 1,000 pages; also small Ruby Magic Lantern, cost $1.50. Box 217, So. Manchester, Conn.

Magic lantern, in good order, condensing lens, 2½ in. diameter, 8 slides. For small photographic camera or offers. H. A. Giddings, 4 Union Place, Classon Ave., Brooklyn.

Printing press, type, etc., worth $13, for offers. E. G. Vogeley, 1010 Bradford St., Pittsburgh, Pa.

Fifty canary birds, with and without crests; fancy poultry, conch shells, strombus alatus. For small printing press, books on natural history, or offers. Frank Lattin, Gaines, N. Y.

A good plain 7 shot revolver, 22 calibre, for a Students' inch or half-inch objective. Frank F. Colwell, Urbana, Ohio.

The Young Scientist

SCIENCE IS KNOWLEDGE.

KNOWLEDGE IS POWER.

A PRACTICAL JOURNAL OF

HOME ARTS.

Vol. V. NEW YORK, JUNE, 1882. No. 6.

Caution to Bee-Poisoners.

FROM notices in several of our exchanges we learn that some thoughtless and ignorant persons, urged by so-called scientific men who certainly ought to know better, are attempting to destroy by poison such bees as annoy them. Aside from the fact that such a practice is contrary to law, to good morals, and to right feeling, those who think of adopting this vile practice should remember that it is not at all impossible that they may take the life of something much more important than a few bees. Some human being may fall a victim and then the poisoner may find himself in the clutches not only of a guilty conscience, but of the law. Nor is it necessary that man, woman or child should find access to the vessels set out for the destruction of the bees; unless under extraordinary conditions the bees will carry to their hives, before they die, an amount of poisoned food sufficient to render the honey in their combs virulently poisonous.

This is not a mere surmise or theory, but a fact which some years ago we demonstrated clearly and fully to our own satisfaction. The records of the experiments were unfortunately destroyed in the great fire which consumed the "World Building" last January, but the results were so clear and unequivocal that we can give them from memory without any material inaccuracy.

In these experiments we established small colonies of bees in locations where they could not interfere with other stocks, and selecting times at which food was scarce, we fed them upon syrup to which poison had been added. In every case we succeeded in destroying the bees, but it was only in a very few cases that we failed to get poison from the honey in the hive, and in these cases the bees took the poison only when no other source of food supply was open to them. In many cases the bees that carried the poison to the hive did not seem to suffer till long after the

young bees were all dead; in some cases the queen was amongst the very first to fall a victim, and next came the young bees, just emerged from the cells.

We used about a dozen different varieties of poison in our experiments, and we fed it to the bees at distances from their hives varying from three feet to a mile and a half. The latter, of course, was easily done by means well known to every bee-hunter.

When arsenic or paris green was used we found no difficulty in detecting arsenic, by means of the usual chemical tests, in the honey taken from the hive. A little of the honey added to the liquid in a Marsh's apparatus readily gave the beautiful characteristic arsenical mirror, and some of the honey fed to mice killed them very quickly.

Nor is this to be wondered at. The honey-sac of the bee is not a true stomach but rather a muscular bag, which exerts very little action on its contents. This is readily seen in the case of the delicate odors of flowers which are retained by the honey in the comb after it has passed through the honey-sac of the bee. Hence, we have clover honey, bass-wood honey, buckwheat honey, etc.—all readily recognizable after they have been deposited in the hive. As might be supposed, therefore, when the bee has but a short distance to go, it invariably succeeds in depositing several loads of the poisoned honey in the hive before it succumbs. When the distance is very great the case is different, and many bees will then die on the way or just after reaching their hives. But in ordinary cases it is only those bees whose hives are quite near that prove an annoyance, and they are the ones that are least affected.

To attempt to poison bees, therefore, is to attempt to mix poison with a common and much-valued article of human food, and the consequences may be of the most serious nature. We feel assured that all that is necessary in order to put a stop to the practice, is the diffusion of accurate knowledge on the subject.

Transporting Aquatic Animals.

BY A. W. ROBERTS.

MANY years ago, before I had had any experience in public aquariums, my method of transporting both marine and fresh-water animals was to change the water at certain well known points along the route of collection, or if marine animals, to always return home on some steamboat over the sides of which, and by means of one of the deck buckets and the kindly assistance of a deck hand, I always obtained a plentiful supply of cool, clean and well oxygenated salt water. This course was particularly necessary during the hot summer months. One day I missed my boat connection, but a good natured Long Island farmer gave me a lift to Brooklyn in his wagon; of course I expected to find all the fish dead. Great was my surprise to find them alive and looking splendid. This fact bothered me

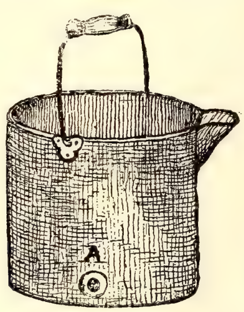

Fig. 1.—Outer Can.

Fig. 2.—Inner Can.

SMALL DOUBLE CAN FOR THE TRANSPORTATION OF FISH.

greatly, and set me to thinking and reasoning out the cause of so strange a phenomenon. I had read in some book that the result of the constant agitation of the ocean by means of tides, winds, and waves was to keep the water in a perfectly fresh condition suitable for the healthy existence of the animal and vegetable life. I then remembered my anxiety regarding the safety of my fish during their journey on account of the constant slashing of the water in the can, as the wagon passed over the rough cobble stone pavements of the streets; and yet the life of my fish had been preserved by this very alarming jolting and consequent agitation of the water. From this experience was suggested the idea of raising the water in the collecting can by means of a hand dipper, and allowing it (the water) to fall from a height of some two feet back into the can, and by this means nose to the surface, clearly detect the change; and so I came to learn that salt water, no matter how foul it may become, can always be restored to a healthy condition for sustaining animal life by resting it in a dark room, then agitating it as above described, and carefully pouring it back into the aquarium after it has rested for a day or so. And thus you see how knowledge was gained by the accidental missing of the steamboat and my ride over the rough streets of B———. For a small collecting can I know nothing better than the one shown in Figs. 1 and 2. Fig. 1 is an ordinary milking can well coated both inside and outside with asphalt varnish; a hole is cut into the side which is strengthened on the inside and outside with a heavy tin collar, as shown at A, into this hole a cork is inserted. Fig. 2 is a can one-half inch smaller in circumference than that shown in Fig. 1, into

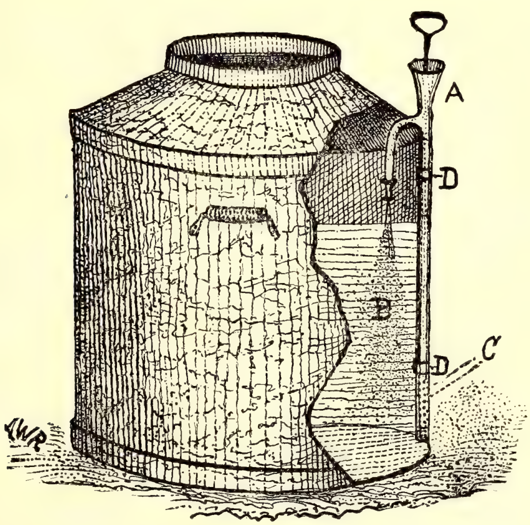

Fig. 3.—ZINC CAN AND PUMP.

driving vast quantities of minute globules of air into the water and thereby oxygenating it thoroughly. I had often saved the salt water contained in my tanks, which had become charged with carbonic acid, by pouring the water back and forth into a pail till it foamed, thereby releasing the poisonous gas and charging the water with oxygen till I could, by placing my which it is intended to fit. On the sides of the can B, eight corks one-quarter of an inch in thickness, are fastened, as shown at C C C, C C C, and also three on the bottom of the can C C C. The sides of the inner can B is perforated with small holes as shown in Fig. 2; at the bottom the perforations cease where the corks are attached as shown in the cut. This inner can is pro-

vided with a short bailer; a close fitting top with very fine perforations will be found to be of great advantage. This double can is operated in the following manner.

The perforated can is placed within the larger can, Fig. 1, both cans are then filled with water, and the animals are placed within the perforated can. When reaching a location where the water can be changed, the inner can is quickly lifted out and the water is allowed to empty out through the perforations till it reaches the space at the bottom of the can that is not perforated; here the animals will remain surrounded with sufficient water; the larger or outer can is then filled with new water, and when this has been accomplished the inner can is placed in position, and is immediately filled. In this way all handling and consequent injury to the fish is avoided. The corks attached to the sides and bottom of the inner can are for the purpose of keeping it in its position and also to prevent it from pressing and jarring against the outer can.

Fig. 3, is a can consisting of heavy sheet zinc strengthened at the bottom and at the elbow and top with galvanized iron bands or hoops. A is a movable hand force pump, which is introduced into the can through two holes situated at the elbow of the can; the body of the pump is passed along the side of the can through two loops or rings of zinc D D. The end of the pump is perforated at the suction end as shown at C. By means of the metal hand pump the dead and exhausted water at the bottom of the can is constantly lifted and dashed against the surface water, thereby thoroughly oxygenating the water in the can, at the same time constant circulation of the water is obtained, which is very necessary when transporting the young of salmon, trout, or black bass. In this can an immense quantity of the lower marine and fresh water animals can be transported successfully.

—Iron or steel immersed in a solution of carbonate of potash or soda for a few minutes will not rust for years.

The Nautilus and Ammonite.

[We have frequently had inquiries for the following poem by the lamented geologist, Richardson. It was printed by Dr. Mantell at the close of a small book written by him and entitled "Thoughts on a Pebble," but has been but rarely reprinted, though it deserves that honor.—Ed. Y. S.]

The Nautilus and the Ammonite
Were launched in storm and strife;
Each sent to float in its tiny boat
On the wide wild sea of life.

And each could swim on the ocean's brim,
And anon its sails could furl;
And sink to sleep in the great sea-deep,
In a palace all of pearl.

And theirs was bliss more fair than this
That we feel in a colder clime:
For they were rife in a tropic life
In a brighter, happier time.

They swam mid isles whose summer smiles
No wintry winds annoy;
Whose groves were palm, whose air was balm,
Whose life was only joy.

They sailed all day through creek and bay,
And traversed the ocean deep;
And at night they sank on a coral bank,
In its fairy bowers to sleep.

And the monsters vast of ages past
They beheld in their ocean caves;
They saw them ride in their power and pride,
And sink in their deep sea graves.

Thus hand in hand, from strand to strand,
They sailed in mirth and glee;
Those fairy shells, with their crystal cells,
Twin creatures of the sea.

But they came at last to a sea long past;
And, as they reached its shore,
Th' Almighty's breath spake out in death,
And the Ammonite lived no more.

So the Nautilus now, in its shelly prow,
As o'er the deep it strays,
Still seems to seek, in bay and creek,
Its companion of other days.

And thus do we, on life's stormy sea,
As we roam from shore to shore,
While tempest-tossed, seek the loved, the lost,
But find them on earth no more.

Yet the hope how sweet, again to meet,
As we look to a distant strand,
Where heart meets heart, and no more we part,
Who meet in that better land.

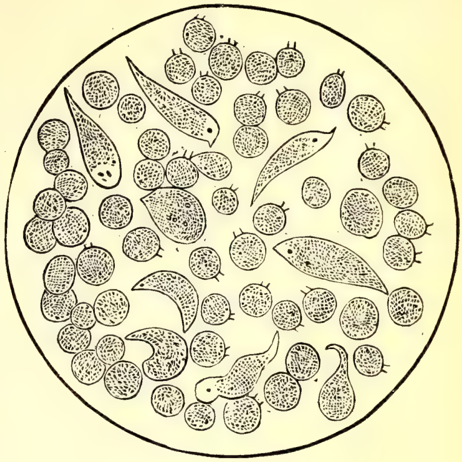
Marvels of Pond Life.—X.

IN the beginning of August a pond in the Finchley Road, a little beyond the Highgate Archway, supplied some more specimens of the *Pterodina patina*, described in a previous article ; but towards the middle of the month a visit to Chipstead, in Surrey, enabled a new region to be explored.

It is always a treat to a Londoner to get down to any of the picturesque parts of Surrey; the trees exhibit a richness of foliage and variety of color not seen within the regions of metropolitan smoke; the distance glows with the rich purples so much admired in the pictures of Linnel, and the sunsets light up earth and sky with the golden tints he is so well able to reproduce. Probably the warmth of the soil, and the purity of the air, may make Surrey ponds prolific in microscopic life; but of this we do not know enough to make a fair comparison. although our own dips into them were tolerably lucky.

Walking one day down a lane leading towards Reigate, where the trees arched overhead, ferns grew plentifully in the sandy banks, and the sunlight flitted through the branches, and chequered the path, we came to a shallow pond, or great puddle, which crossed the way, and near the edge of the water the eye was struck with patches of crimson color. On attempting to take up a portion of one of these patches the whole disappeared, although when the disturbance ceased the rich color again clothed the dingy mud. The appearance was caused by thousands of little worms, belonging to the genus *Tubifex*, not uncommon in such situations, who thrust themselves out to enjoy the light and air, and retreat the moment an alarm is given. Probably both actions belong to the class described in the last article, as "reflex;" but it would be interesting to know whether creatures so humble have any sense of fear. These worms will repay observation, but in these pages we eschew all their tribe—unless the rotifers be assigned to them—and take ourselves once more to our especial subjects.

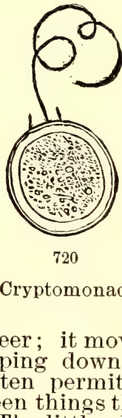
Knowing that farm-ponds are usually well stocked with microscopic game, we made a dip into one more especially assigned to ducks, and obtained wondrous little for our pains. We were not, however, discouraged, but made an examination of the circumstances, which determined a particular course of action. Our piece of water was simply a dirty duck-pond, in which no large plants were growing, and which did not even exhibit the little disks of duckweed that are common to such situations. There was, however, on the surface, in parts, an exceedingly fine scum of pale yellow green, and this, armed with a teaspoon, we proceeded to attack. By careful skimming, a small bottle was half-filled with minute organic particles, which were likely to be interesting in themselves, and pretty sure to be the food for something else. A small drop was placed on a tablet of the live-box, flattened out by the application of the cover, and viewed with a power of two hundred linear, which disclosed swarms of brilliant green globes, amongst which were a good sprinkle of minute creatures, like the *Euglenæ* already described, and whose little red eyes contrasted vividly with the prevaling emerald hue.



200

Cryptomonad—Euglena.

One of the higher infusoria, whose species I could not identify, was devouring them like a porpoise among sprats. It did not, however, exhibit any sense in its hungry career; it moved about in all directions, gulping down what came in its way, but often permitting the escape of the little green things that were almost in its mouth. The little globes rolled and whirled about without the fair test indica-



720

Cryptomonad.

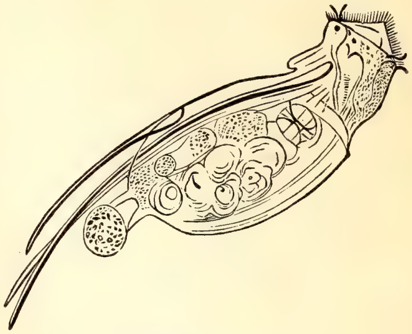
tion of a purpose, and without exhibiting any instrument with which their locomotion was effected. To find out how this was done, a higher power was used, and from their extreme minuteness an amplification of seven hundred and twenty linear was conveniently employed, although a lower one (three or four hundred) disclosed the secret by showing that a little whip was flourished about through the neck, which the lower power revealed. When highly magnified, each little globe was seen to consist of an outer case of a reddish orange color, which was noticeable on looking at the edges, although in the centre it was transparent enough to show the brilliant green contents, that resembled the chlorophyl, or green coloring matter of plants. From a short neck proceeded the whip-like filament, which was lashed and twisted about in all directions. These little creatures belong to the monad family, but whether they are to be called *Trachelomonads*, or by some other hard name, the learned must decide.

The 'Micrographic Dictionary' puts a note of interrogation to the assertion of some writers that *Trachelomonads* have no necks, and draws some with such an appendage.

Pritchard's last edition is against necks, and whether the necks or no necks are to win, is a mighty question, equal at least to the famous controversy, which divided the world into "big and little endians in the matter of breaking eggs."

A discussion of more importance is, whether these *Cryptomonads*—that name will do whatever comes of the neck controversy—are animals or vegetables. Lachmann and Mr. Carter affirm that they have detected a contractile vesicle, which would assimilate them to the animal series, but their general behavior is vegetable; and the 'Micrographic Dictionary' is in favor of referring them to the *Algæ*—that great family of simple plants, of which the sea-weeds are the most important representatives.

When any of the monads swarm, there are sure to be plenty of other creatures to eat them up, and in this instance the predaceous animalcule, already described, was not the only enemy the little green globes had to suffer from, as two sorts of rotifer were frequently met with. One of these was a very handsome and singular creature, which in some positions had the general contour of a cockatoo, only that the legs were wanting, and the head exhibited a monkey face. The "wheels" were represented by ciliary tufts, and two bright red eyes twinkled with a knowing look. From each shoulder proceeded a long curved spine, and about two-thirds down the body, and lying between the two long spines, a shorter one was articulated, which followed the same curve. A gizzard was busy in the breast, and the body terminated in two short toes which grasped a large round egg. Whenever the cilia were drawn in, the three spines were thrown up; but they had an independent motion



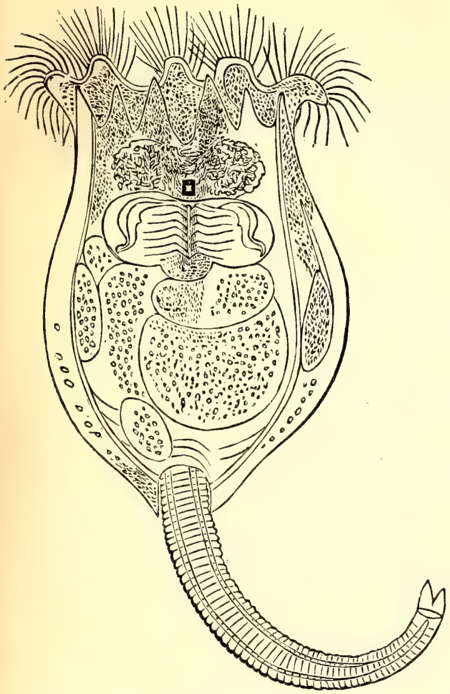
Triarthra. × 130.

of their own, and every now and then were jerked suddenly and violently back, which occasioned a rapid change in the creature's position. The gizzard appeared to consist of two rounded masses, having several ridges of teeth, which worked against each other something like the prominences of a coffee-mill. From the three spines, this animal was a *Triarthra*, or Three-limbed Rotifer, but the position of the spines, and the toes, made it differ from any species described in the 'Micrographic Dictionary,' or in Pritchard.

Whether or not this species is to be regarded as having a lorica or not, must depend upon the precise meaning attached to that word. At any rate the integument was much firmer than in many of the rotifers, and gave an efficient support to the spines which a mere skin could not do. As Mr. Gosse remarks of an allied genus, the *Polyarthra*, or Many-limbed Rotifer, this creature could not be investigated without coming to the conclusion "Here again we have true jointed limbs;" a fact of great importance in determining the zoological rank of the family, and in supporting Mr. Gosse's view some at least bore a strong affinity with the group of *Arthropoda*, of which the insects are the principal representatives.

Another rotifer of even greater interest, which was busy among the Cryptomonads, was the Brachion, or "Pitcher Rotifer" (Brachionus). The members of this genus will frequently reward the scearcher into pond-life. Their main characteristic is a cup or pitcher-shaped lorica, which is cut or notched at the top into several horns or projections, the

number of which indicates the species; while two or more similar projections ornament the bottom. This lorica is like the shell of a tortoise open at both ends; from the top an extremely beautiful



Brachionus Urceolaris. × 240.

This drawing has been accidentally reversed by the engraver, which alters the relative place of the internal organs.

wreath of cilia is protruded and also some longer and stiff cilia, or slender spines, which do not exhibit the rotatory movement. The ciliary apparatus is in reality continuous, but it more often presents the appearance of several divisions, and the lateral cilia frequently hang over the sides. From the large size of each cilium they are very favorable creatures for exhibing the real nature of the action, which gives rise to the rotatory appearance, and which can be easier studied than described. By movements, partly from their base, and partly arising from the flexibility of their structure, the cilia come alternately in and out of view, and when set in a circular pattern, the effect is amazingly like the spinning round of a wheel. The internal arrangements of the Brachiones are finely displayed, and they have a most aldermanic allowence of gizzard, which extends more than half way across each side of the median line, and shows all the portions described by Mr. Gosse. As the joints of this machine move, and the teeth are brought together, one could fancy a sound of millwork was heard, and the observer is fully impressed with a sense of mechanical power.

When the creature is obliging enough to present a full front view, her domestic economy is excellently displayed. The prey that is caught in her whirpool is carried down by a strong ciliary current to the gizzard, which may be often seen grappling with objects that appear much too big for its grasp; and Mr. Gosse was lucky in witnessing an attempt to chew up a morsel that did actually prove too large and too tough, and which, after many ineffectual efforts, was suddenly cast out. As soon as food has passed the gizzard, it is assisted in its journey by more ciliary currents, which are noticeable in the capacious stomach, in the neighborhood of which the secreting and other vessels are readily observed. Just over the gizzard blazes a great red eye, of a square or oblong form, and it reposes upon a large mass of soft granular-looking brain, which well justifies Mr. Gosse's epithet "enormous." Whether this brain is highly organized enough to be a *thinking* apparatus, we do not know, but it is evidently the cause of a very vigorous and consentaneous action of the various organs the Brachion possesses.

A description of the Brachion would be very incomplete if it omitted that important organ the tail, which in this family reaches the highest point of development. It is a powerful muscular organ, of great size in proportion to the animal, capaple of complete retraction within the carapace, and of being everted wholly, or partially, at will. It terminates in two short conical toes, protruded from a tube-like sheath, and capable of adhering firmly even to a substance so slippery as glass. This tail may be observed to indicate a variety of emotions, if we can ascribe such feeling to a rotifer, and it answers many purposes. Now we see it cautiously thrust forth, and turned this way and that, exploring like an elephant's trunk and almost as flexible. Now it seizes firm hold of some substance, and anchors its proprietor hard and fast. A few moments afterwards it lashes out right and left with fury, like the tail of a cat in a passion. Then again it will be retracted, and a casual observer might not imagine the Brachion to be furnished with such a terminal implement.

The Brachiones may often be seen with one or more large eggs stuck about the upper part of the tail, and others may be discerned inside. One specimen before

us has three eggs attached to her in this way. They are large oval bodies, with a firm shell. These creatures differ very much in appearance, according to the direction in which they are seen, and a side view makes them look so different from a full front or back aspect, that it would be easy to suppose another animal was under observation. The extent to which the ciliary apparatus is protruded, and the pattern it forms likewise differs continually; and hence no drawing, however correct, is sure to resemble the arrangement that may be presented to the observer's eye. But however our little "Pitcher" may be viewed, it is sure to prove a spectacle of interest and delight.

Burnishing.

BY burnishing, the roughness of an object is flattened down until the surface is smooth and polished like a looking-glass. Burnishing is an important operation for electro-deposits, which consist of a multitude of small crystals, with intervals between them, and with facets reflecting the light in every direction. The deposited metal is hardened and forced into the pores of the underlying metal, and the durability is thus increased to such an extent that, with the same amount of silver, a burnished article will last twice as long as one which has not been so treated. The instruments employed for burnishing are made of different materials, and must be of great hardness and a perfect polish—such as hardened cast steel, agate, flint, and bloodstone. For metallic electro-deposits steel and bloodstone are especially employed. There are several qualities of bloodstone; its grain should be close, hard, and without seams or veins; it should leave no white lines on the burnished parts, nor take off any metal, and its color should be of an intense black red. The steel must be fine and close grained, and perfectly polished. Should the polish of any burnishing tool alter by use, it is restored by friction upon a skin or leather attached to a wooden block, which is fixed to the bench. The leather is covered with polishing rouge in impalpable powder, or, preferably, with pure alumina, obtained by calcining ammonia alum in a forge fire. Venetian tripoli, rottenstone, tin putty, emery, or many other hard substances finely powdered, may be employed. The burnishing tools are of various shapes, such as a lance, a tooth, a knife, a half sphere, or a dog's tongue, and a considerable stock is necessary. The burnishing is divided into two distinct operations. The first consists in roughing, and the second in finishing. The tools for the first have a sharp edge, while for the second operation they have a rounded surface. The tools for the hand or the lathe are fixed by copper ferrules into short round wooden handles, so that the hand is not influenced by their weight. The tools for the arm or vise are fastened to wooden handles sufficiently long to rest their slender part upon the arm or shoulder. The stouter lower portion is grasped by the hand. The burnishing tools and the objects must be frequently wetted by certain solutions, some of which facilitate the sliding of the instrument, or with others which have a chemical action upon the shade of the burnished articles. Of the first are pure water, solutions of soap, decoctions of linseed, and infusions of the roots of marsh mallow or licorice. The second includes wine-lees, cream of tartar, vinegar, alum in water. When burnishing gold applied upon electro-deposits of copper, as in gilding with a dead lustre by that method, use pure water, for fear of producing a disagreeable red shade. A solution of green soap is sometimes preferred by operators, although when old it imparts an unpleasant tinge, owing to the sulphides of the liquor. When the burnishing is completed, the surface is wiped longitudinally with a soft and old calico rag. The polish obtained by burnishing is called black when it reflects the rays like a mirror; and should the presence of mercury or a bad deposit prevent the tool from producing a bright surface, the object is said to be greasy. Articles which have been previously polished, and which generally receive a very trifling deposit, are not burnished, but rubbed with chamois leather and the best polishing rouge. Too thick or too rapid electro-deposits cannot be burnished, but must be polished by rubbing with a leather and a mixture of oil and powdered pumice-stone, tripoli or tin putty. Coarse powders are used at the beginning, and impalpable ones at the end of the operation. Polished silver deposits are more agreeable to the eye than burnished ones, but the hardening of the latter renders them more durable. —*Metal Worker.*

Cleansing Soiled Chamois.

SOILED chamois is often thrown aside and wasted for the want of knowing how to clean it. Make a solution of weak soda and warm water, rub plenty of soap into the leather and allow it to remain in soak for two hours, then rub it well until it is quite clean. Afterward rinse it well in a weak solution composed of warm water, soda, and yellow soap. It must not be rinsed in water only, for then it would be so hard, when dry, as to be unfit for use. It is the small quantity of

soap left in the leather that allows the finer particles of the leather to separate and become soft like silk. After rinsing, wring it well in a rough towel and dry quickly, then pull it about and brush it well, and it will become softer and better than most new leathers. In using a rough leather to touch up highly polished surfaces, it is freqently observed to scratch the work; this is caused by particles of dust, and even hard rouge, that are left in the leather, and if removed by a clean rougey brush it will then give the brightest and best finish, which all good workmen like to see on their work.

Ebonizing Wood.

ALL the world now knows of those articles of furniture of a beautiful dead-black color, with sharp, clear-cut edges, and a smooth surface, the wood of which seems to have the density of ebony. Viewing them side by side with furniture rendered black by paint and varnish, the difference is so sensible that the considerable margin of price separating the two kinds explains itself without need of any commentary. The operations are much longer and much more minute in this mode of charcoal polishing, which respects every detail of the carving, while paint and varnish would clog up the holes and widen the ridges. In the first process they employ only carefully selected woods, of a close and compact grain; they cover them with a coat of logwood dissolved in water, and almost immediately afterwards with another coat, composed chiefly of sulphate and acetate of iron. The two compositions, in blending, penetrate the wood, and give it an indelible tinge, and, at the same time, render it impervious to the attacks of insects.

When these two coats are sufficiently dry, they rub the surface of the wood at first with a very hard brush of couch-grass (*chiendent*), and then with charcoal of substances as light and friable as possible, because if a single hard grain remained in the charcoal, this alone would scratch the surface, which they wish, on the contrary, to render perfectly smooth. The flat parts are rubbed with natural stick charcoal, the indented portions and crevices with charcoal powder. At once, almost simultaneously, and alternately with the charcoal, the workmen also rubs his piece of furniture with flannel soaked in linseed oil and the essence of turpentine. These pouncings, repeated several times, cause the charcoal powder and the oil to penetrate into the wood, giving the article of furniture a beautiful color and perfect polish, which has none of the flaws of ordinary varnish. Black wood, polished with charcoal, is coming day by day to be in greater demand; it is most serviceable; it does not tarnish like gilding, nor grow yellow like white wood, and in furnishing a drawing-room, it agrees very happily with gilt bronzes and rich stuffs. In the dining-room, too, it is thoroughly in its place to show off the plate to the greatest advantage, and in the library it supplies a capital framework for handsomely bound books.—*Cabinet Maker*.

Mosaics.

THE extraordinary delicacy and accuracy acquired by workers in Mosaic, both as regards shape and color, form a marked illustration of the power of physical education. In a portrait of Pope Pius V. there were, 1,700,000 pieces each no larger than a grain of millet. The enamel is a kind of glass colored with metallic oxides, which is fused and drawn out into threads, small rods, or oblong sticks of varying degrees of fineness, slightly resembling the type used by compositors. These many colored rods are kept in drawers properly numbered, so that the artist always knows to which case to repair when he requires a fresh supply of a particular tint or tints. When the picture is commenced the first step is to place on the easel a slab of marble, copper, or slate, of the sized fixed upon; and this slab is hollowed out to a depth of about three and a half inches, leaving a flat border all round which will be on a level with the completed mosaic. The excavated slab is intersected by transverse grooves or channels so as to hold more tenaciously the cement in which the mounts of enamel will be embedded. Then the hollowed slab is filled with "gesso," or plaster-of-Paris, on which the proposed design is accurately traced in outline, and usually in pen and ink.

The artist then proceeds to scoop out a small portion of the plaster with a little sharp tool. He fills up the cavity thus made with wet cement or "mastic," and into this mastic he successively thrusts the "spiculæ," or the "tesseræ," as the case may be, according to the pattern at his side. In the broad folds of drapery or in the even shadows of a background, or a clear sky, his morsels of enamel may be as large as one of a pair of dice; in the details of lips, or eyes, or hair, or foliage, or flowers, the bits of glass may be no larger than pins' heads. The cement, or mastic, is made in various ways, the best being formed of slaked lime, finely powdered Tiburtine marble, and linseed oil, and when thoroughly dry is as hard as flint. Sometimes the mastic which fills the cavity is smoothed and painted in fresco with an exact replica of the pat-

tern, and into this bits of glass are driven, according to tint, by means of a small wooden mallet. If the effect produced wounds the artist's eye, he can easily amend the defect by withdrawing the offending piece of enamel and driving in another while the cement is still wet; and, by observing proper precautions, it can be kept damp for more than a fortnight. When the work is completed any tiny crevices which may remain are carefully plugged or "stopped" with pounded marble, or with enamel mixed with wax, and the entire surface of the picture is then ground down to a perfect plane, and finally polished with putty and oil. Byzantine may be broadly distinguished from Roman mosaic by the circumstance of the surface of the former being left unground or unpolished—save where there is burnished gold—thus leaving an irregularity of surface productive of great vigor of effect. A picture of the Byzantine style can at once be recognized as a mosaic, even if it be hung at an altitude of one hundred feet from the ground; but a perfected mosaic picture, after the Roman manner, might easily be mistaken, even at a very short distance, for a very elaborately finished and highly varnished painting in oils.

How to Make an Electric Battery.

Amateur experimenters in electricity will find the following battery an exceedingly cheap, yet strong one. Anyone with care and thought can make it.

The materials used are as follows: One common fruit jar, one piece of zinc, twelve inches by three wide, a small flower-pot (unglazed) about three inches deep, piece of gas-carbon, two ounces of bichromate of potash, two ounces of sulphuric acid and three ounces of common salt.

We will begin with the jar. Dip in kerosene about one yard of twine and wind it around the jar about three inches from the bottom. Ignite it and slowly revolve the jar in the hands so as to have the flame on all sides of the jar at once. When the jar cracks, strike the open end with a piece of wood and the jar will crack off where the string was placed. Remove the sharp edges with a file and the battery jar is finished.

Solder a piece of copper wire to one corner of the zinc and then roll it into a cylinder form about the size of the jar. The wire from this zinc constitutes the negative pole of the battery. With a little melted tar stop the hole in the bottom of the flower-pot.

At the gas factory obtain a piece of gas-carbon the size of your wrist and three or four inches long. Drill a small hole in one end and twist a stout piece of copper wire into it. Apply a little melted tar around the wire where it enters the carbon, which will partly protect it from the attacks of acid. This wire from the carbon constitutes the positive pole from which the electricity flows.

To prepare the acid, place a pint of warm water in a bottle, and add the bichromate; when nearly dissolved add the sulphuric acid. In preparing this acid be very careful as it is very poisonous and corrosive.

In the bottom of the jar place the salt. Then place in the zinc. Inside of the zinc place the pot. Into the pot place the carbon with the wire projecting upwards. Fill this pot with the acid. Fill the jar within one-quarter of an inch of the top of the pot with water. In a few moments the battery will be ready to work. Connect the wires and the circuit is complete from the carbon to the zinc. When in a dark room a bright electric spark may be seen at the moment the wires are disconnected. Therefore, electric phenomena is only obtained when there is a metallic circuit between the positive and negative poles.

To maintain the battery, recharge the pot with acid about once in two or three weeks, according to the use. Renew the salt water about once in a month. A number of experiments may be performed with this battery, one of which I will describe in the next number.

GEORGE THOMPSON.
Malden, Mass.

Luminous Paint.

The comparatively recent discovery that luminous paint can be applied as ordinary whitewash, considerably expands the field of its usefulness. Sheets of glass coated with the paint form Aladin's lamps, which are in use in some of the vessels of the navy, at the Waltham Powder Factory, at Young's Paraffine Works, and in the spirit vaults of several docks; but now that, by increased production and the use of water as the medium, the cost is reduced by one-half, it will probably be extensively used for painting walls and ceilings. The ordinary form of oil paint has already been applied in many ways to clock-faces, to name-plates and numbers and house doors, and to notice boards, such as "mind the step," "to let," etc. The paint emits light without combustion, and, therefore, does not vitiate the atmosphere. Several experimental carriages are now running on different railways, the paint being used instead of lamps, which are necessary all day on account of the line passing through occasional tunnels. It is reported that a paper at Turin called *Light* is to appear shortly, printed in ink

which will be luminous when darkness sets in. Who can say, indeed, that a policeman, when smeared in this luminous composition, will not be sometimes visible on his beat at night?

The following method of procedure will, it is said, give a very satisfactory luminous paint: Take a number of oyster shells, cleaned from organic matter as thoroughly as possible, and burn them in a strong coal fire for about half an hour, at the end of which time take them out and allow to cool. When quite cold, pound them fine, removing, during this operation, any particles of gray matter that may show themselves, as these are useless. When finely powdered, make an intimate mixture of this with flowers of sulphur. Introduce the mixture into a crucible, luting on a lid to the vessel with clay, or other convenient luting material. When this is dried, place the crucible in the fire and allow it to remain for an hour; then remove, and allow to cool before opening. The mixture then should appear pure white. Any gray particles that have escaped removal at the first preparation, should be removed now. The resulting powder should be mixed with gum water to a thin paint, as two thin applications are better than one thick one. This paint will remain luminous far into the night, provided it is exposed to the light during the day.—*Building News.*

Polishing Glass.

Besides the oxide of zinc (commonly called ashes of zinc), is usually used for the cutting and polishing of glass. In glasses intended for optical purposes, the very finest polish can, of course, be only obtained by exceedingly fine grained oxide of iron. But since such an article can not always be obtained, and even oxide of iron prepared after Vogel's receipt from oxidulated protoxide of iron does not always answer the purpose, the glasses polished with it sometimes looking dim and brown yellow, because the finest particles of the preparation enter the pores of the glass, Professor Dr. J. I. Pohl made experiments with oxide of zinc. The result answered, as *Dingler's Polytechnical Journal* states, perfectly the expectations entertained. The sorts used were: 1. The finest white zinc, such as the factory of Peteswald, in Silesia, puts into the market. Of these the grey zinc was found particularly well adapted to cut glass, while the Hamburg white answered for common polishing. The finest white zinc was found to be excellent for the so-called "high polish" of optical glasses. White zinc does not only polish quickly, but with the finest sort the very highest white brilliancy can be obtained. For polishing the very expensive optical glasses, Prof. Pohl considers the white zinc known in France under the name of *blanche de niege* (*i. e.*, snow white) best adapted.

Practical Hints.

To Clean Bronze Statues.—The objectionable dark coating which most bronze statues soon acquire, with the look of cast iron, may be very quickly and completely washed off by means of a concentrated solution of carbonate of ammonia, applied with brushes. Thereupon a layer of patina is formed, which guards the statue against fresh formation of the dark coat. The work should, of course, only be entrusted to skilled and intelligent men. Another method is to paint the statue, at intervals of a few weeks, repeating with a solution of 20 parts anhydrous vinegar in 100 parts bone oil. The acetate and oleate of copper salts thus produced, form first a thin green layer, which hinders the attachment of dirt and dust, and occasions further patina formation.—*English Mechanic.*

A Screw-Driver Improvement.—Most people who use screw-drivers must be occasionally inclined to use strong language at their persistency in slipping out of the nick, and their refusal to go into it. All that is wanted is a short tube, big enough to enclose the screw-head somewhat tightly, but only spring-tight, so that it may rise as the screw-head comes near the wood. Also, to provide for heads of different sizes with the same driver. All this can be done by just turning up a strongish tin tube, three or four inches long, like a slate pencil case, big enough to slide over the widened point of a round screw-driver, and then fitting spring-tight on the shank by means of a piece ef leather wrapped round it; and for larger screws than usual, you might pull the socket off and put a larger on, with a thicker piece of leather. I find it answers perfectly. You need not even look at your screw, but just put the tubed screw-driver on, and turn. It will drop into the nick at the first half-turn, and stay there till the screw is screwed home.—*English Mechanic.*

Pocket Knives.—The thwytel or whittel of Chaucer's period was a very poor, rude instrument, consisting of a blade of bar steel fastened into a wooden or horn handle. It was used for cutting food, as well as for the numerous miscellaneous duties which now fall to the pocket knife. To the whittel succeeded the Jack-Knife—the Jacques-de-Liege, or Jock-te-leg of the Scottish James VI—which formed the prototype of the modern clasp knife, inasmuch as the blade closed into a groove in the handle. This improved form was probably introduced into Sheffield by Prostestant refugees from the Low countries, who came to England during the reign of Queen Elizabeth, Shortly thereafter, about the beginning of the 17th century, the pocket knife with spring back was introduced, and no marked improvement took place till the early part of the present century.

Mechanical Equivalent of Heat.—It does not appear to be generally known that the value of the mechanical equivalent of heat has within a few years been corrected. It is generally referred to by mechanical writers at 772 foot pounds. Dr. Joule repeated his famous experiments in 1876, nearly six years ago, with extraordinary precautions, and the mean result of sixty experiments gave 774.1 foot pounds with a possible error of 1.400, on account of the "thermometric scale error." This value should be used in all calculations relating to the value of heat as a motive power.

EXCHANGES.

Only those who are *yearly* subscribers, and whose names are entered on our books have the privilege of inserting exchanges.

Exchanges must be on separate slips of paper or postal cards. If mixed with business matter in letters or cards they are filed away and never reach the printer.

Exchanges must not exceed thirty words.

Buying and selling belong to the advertising department.

We reserve the right to omit the exchange column, when we have not room for it, and the amount of space at our disposal will regulate the number of insertions given to each *exchange*, the preference being always given to those who have not previously used our columns.

Blow-pipe set (cost $10), large illustrated family Bible (cost $7.50), for Wood's Botany, Dana's Geology, or printing press and type. H. W. Noble, Box 134, South Dansville, N. Y.

Wanted, offers for fossil shells from the west coast of Africa. A. W. Seward, 187 E. 71st St.

I have a number of birds' eggs I should like to trade for other birds' eggs; send for list of trading eggs. A. G. G., Box 26, Summit, New Jersey.

For a microscope stand or offers, a 36-inch turning lathe (new) and a number of scientific books; send for list. A. Kendall, Somerville, Mass.

Wanted services of amateur printer with small office (or large), in exchange for an interest in a well-established weekly paper, good size. Eagle Office, Plymouth, N. H.

American Agriculturist microscope, new, cost $15, for amateur photographic apparatus, lever watch, 22 calibre breech-loading sporting rifle or magic lantern of equal value. Wm. A. Walker, Rockland, R. I.

I. T. Bell, Franklin, Pa., has back numbers of Scientific American, Forest and Stream, and Young Scientist, good flute, chessmen, books, etc., for good magic lantern, revolver, scarce coins, or offers.

A steel spring bracket-saw, 2 doz. saw blades, and about 1 doz. patterns for a good stylographic pen or offers; send postal before exchanging. Geo. Oakley, Rutherford, N. J.

A rosewood banjo, 11 inch head, 12 nuts, fully strung, together with lot of dime banjo music and instructions, for microscope, Webster's Unabridged, monkey, squirrel and cage, or offers. J. DeWitt Clark, P. O. Box 37, Brooklyn, N. Y.

For self-inking printing press and type, one Henry rifle, 16 shot, 44 cal., cost $40, in good order, or one double barrel shot gun, barrels London fine twist, or offers. J. B. Garrison, Belton, Bell Co., Texas.

A new 40 diameter microscope, corals, and minerals, for a stylographic pen, air gun, or offers. J. McBride, 54 Garley St., Chicago.

What offers for "The Chefs D'Oeuvre D'Art, Paris Exhibition 1878," cost $16, good as new, bound; 1 large photo camera, complete, cost $95; Scientific American from 1859 to 1880, 4 vols. bound. D. Keesler, Stony Point, N. Y.

Sea shells of Atlantic coast, scientifically marked, for books, old or new magazines, Indian relics, natural history specimens, apparatus; anything Wilfred Leon Miller, P. O. Box 392, Cape May, N. J.

A dulcimer that cost $20, books and fossils, for a telescope, microscope, fossils, Indian relics, or offers. E. J. Votaw, Salem, Iowa.

A self-inking model press, 5 x 7½, cost $23; $90 worth of scroll-saw designs in lots to suit; Scientific American, 1880; Palliser's Useful Details, $3; for photo outfit or offers. C. H. Parker, Coldbrook Springs, Mass.

Telegraph key and sounder, Frank Leslie's Illustrated Magazines, mounted microscopic objects, natural curiosities, for bull's-eye condenser, photograph camera, Unabridged Webster Dictionary, or offers. W. T. Alan, Greenville, Mercer Co., Pa.

Large magic lantern, spectroscope, pantagraph, for enlarging drawings, rosewood writing desk, man's saddle, for microscope, photo outfit or offers. Thomas Walters, Bergen St., East of Brooklyn Ave., Brooklyn, N. Y.

Model card press, chase 3¼ x 5¼, with 4 fonts type, cases, etc., for good foot lathe. Mills Day, 2 Farmington Av., Hartford, Ct.

French microscope, inclines to any angle, delicate fine motion, neat upright case, cost $17.50, for scientific books; send list to W. Fitz, P.O. Box 2852, New York.

Wanted, Quinby's New Bee Keeping, for Our Own Birds of the United States, by W. S. Baily; new. Joseph Anthony, Jr., Coleta, Whiteside Co., Illinois.

Printing type, small pica; large and small capitals, and small letters; 60 to 65 lbs., including two large cases; also gothic nonpariel, for trade. J. Siler, 1242 Broadway, St. Louis, Mo.

One years' copy of Aldine, cost $5.50, and German accordion, with instructions how to use it, cost $5.00, for offers. Chas. Dempwolf, 86 Benson St., Paterson, N. J.

A Novelty printing press, with type, prints a form 5 x 7 inches, cost $40.00, for a microscope, photographic apparatus, or offers. T. W. Patterson, Warsaw, N. Y.

$80 worth of (nearly new) printing material, minerals, fossils, Aboriginal relics, etc., for scientific books, good American watch, and offers. F. M. Farrell, Cobden, Union Co., Ills.

Rocks, minerals, fossils and fresh water shells for microscope stand, $20 to $75, also for objectives, turning lathe type, and tools. D. D. Babcock, South Dansville, N. Y.

Mechanical Electricity, Medical Chemistry, by Robert Hare; Fruits and Farinacea, by Trall; Complete Herbalist, by O. P. Brown; for mounted objects for the microscope or offers. J. B. Playter, Bristow, Butler Co., Iowa.

Violin (cost $10) and 5-shot 32-cal. revolver (cost $4), for photo-camera lens and tube, watch, parlor rifle, extra well-bred canary birds, or offers. C. Maides, St. Louis, Mo.

To exchange for a wood-turning lathe or offers, a Young America Self-inking Printing Press, with type and outfit complete; chase 3 x 5 inches. Embury McLean, 318 Bloomfield St., Hoboken, N. J.

What offers for "Our First Century," cost $7.00, bound in sheep, over 400 illustrations, 1,000 pages; also small Ruby Magic Lantern, cost $1.50. Box 217, So. Manchester, Conn.

Magic lantern, in good order, condensing lens, 2½ in. diameter, 8 slides. For small photographic camera or offers. H. A. Giddings, 4 Union Place, Classon Ave., Brooklyn.

Printing press, type, etc., worth $13, for offers. E. G. Vogeley, 1010 Bradford St., Pittsburgh, Pa.

Fifty canary birds, with and without crests; fancy poultry, conch shells, strombus alatus. For small printing press, books on natural history, or offers. Frank Lattin, Gaines, N. Y.

A good plain 7 shot revolver, 22 calibre, for a Students' inch or half-inch objective. Frank F. Colwell, Urbana, Ohio.

Good Writing.—No one can write rapidly and legibly without a good pen, and unfortunately there are many pens in market that are not good. The majority of writers find that Esterbrook's Falcon steel pen suits their hand, and our experience is that no pen retains its good qualities longer.

HOME ARTS.

VOL. V. NEW YORK, JULY, 1882. No. 7.

Practical Hints on the Construction of the Violin—III.

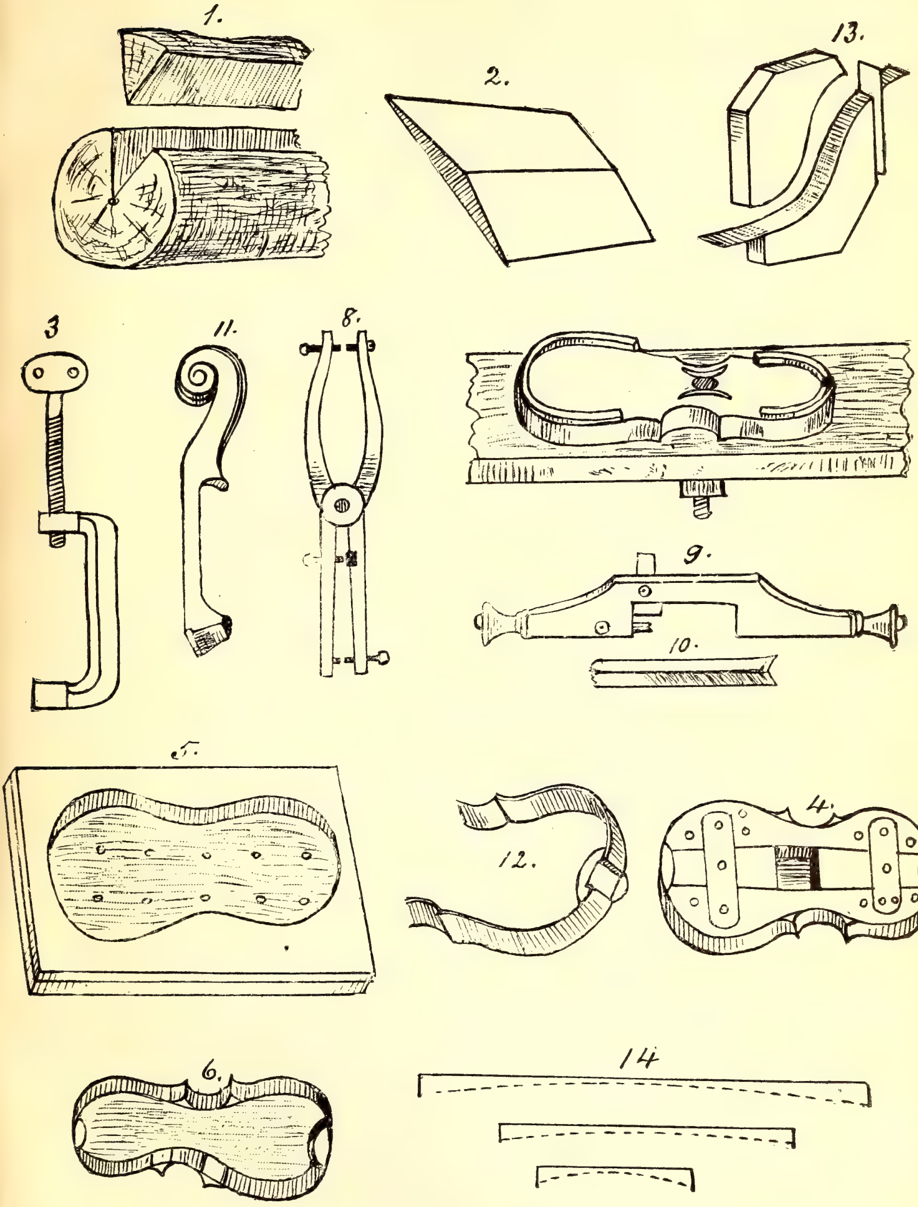
IN our last chapter we gave a brief sketch of the manner of preparing the mold and setting up the sides, but we omitted a very important item. The quality of the tone of a violin depends in a great measure on the quantity of air contained. The back and belly of the instrument may be most gracefully modeled, and of the proper thickness, but if the quantity of air contained within, be either deficient or in excess, the tone will always remain bad. The reason of this is evident. It is the air within the instrument which, when put in motion by the vibration of the back and belly, produces the sound. Now if the internal capacity of the instrument be too great, the air will be in excess, and consequently the tables are not able to give it the number of vibrations in a given time necessary to produce the right quality of sound. On the other hand, if the capacity of the body of the violin be too small, the tables will give the air contained too much vibration. In the first case, the tone will be hollow and dead, in the latter shrill and harsh. The air contained in a good violin should, when vibrated by blowing into one of the sound holes, give the note C on the G string of the instrument. As the amateur will find great difficulty in getting by calculation the right size, let him choose a good instrument and follow its proportions with accuracy. By comparing different instruments he will see a great difference in the form and manner of construction. Some have the tables very much elevated, while those of others are very flat, but he will also, on careful examination, find in all good violins, that when the tables have a high model the other dimensions are less than in those whose tables are less elevated. This is for the reason given above, namely, to regulate the inside

capacity so that the air contained may be, as near as possible, the same, no matter what the outward shape may be. With these preparatory remarks, we will now proceed to explain the manner in which the back and belly are fashioned.

We will suppose the parts have been properly glued together. A pattern of zinc or cardboard of the exact size and shape is laid on and the outlines marked with a sharp pencil. Then, with a good scroll saw, cut all the way around, following the pencil mark as closely as possible. The amateur must have a bench on which to work out his model. Let him take a block of good hard wood about two inches thick, of the same shape as his violin plate, but somewhat larger. Let him cut a few strips of white holly about an eighth of an inch thick, so that they may roughly fit around the edges of his plate, cutting small slots in them, and screwing them down to his bench with round-head screws, so as to clamp the plate firmly; the slots are for the purpose of sliding the clamps backwards or forwards when the screws are slackened so as to release the plate. Let him then hollow out his bench in the centre to make it correspond roughly to the swell of his instrument, and fasten it to a cabinet-maker's or carpenter's bench with a strong bolt having a nut beneath so that he may swivel his work-bench or make it fast at pleasure (see Figure 7). He is now ready to begin the modeling of the outside of his plate. Having chosen a good violin as a pattern, he takes a few strips of wood about an inch and a half wide by an eighth thick. These he lays edgewise on the back of his pattern violin, and with a scribing tool, marks on them the swell of the instrument. He then cuts out with a sharp knife, following the scribe. These will guide him in working the outside of his back (see Figure 14). The roughing off may be done with large gouges and chisels, but the finishing must be done with steel scrapers and sand-paper. In the final polishing the sand-paper should be very fine, and the plate should be wet from time to time so as to raise all the loose fibres of the wood, that they may be cut off cleanly, leaving a smooth glossy surface. When the surface of the plate has been properly finished, the next operation is to trim and round the edges neatly with a file and sand-paper. The plate is now ready for the purfling or fillets. This part of the work requires great care. The fillets are thin strips of wood glued together—usually a centre-piece of ebony and two outside pieces of white holly. A recess is cut with a tool made especially for the purpose around the edge of the plate, the fillets are inserted, glue being previously laid in the recess, neatly mitered at the corners and tapped down firmly in their place.

Before proceeding further, we deem it advisable to furnish cuts of the principal appliances used by violin-makers. Figure 1 shows the manner in which the sections of wood are cut from the tree. Figure 2 will serve to give an idea of how the sections are glued together. Figure 3 is an iron screw-clamp which will be found very useful. Figure 4 is the mold on which the sides are set up. Figure 5 is the frame in which the mold is screwed fast in order that the sides may be wedged tight to the mold and glued to the blocks and corners. Figure 6 shows the sides in position and glued in their places. Figure 7 is the work-bench. Figure 8 callipers for gauging the thickness of the back and belly. Figure 9 shows the purfling tool, and 10 the cutter. The purfling tool should be made of brass, as in the engraving, with swiveling knobs at each end, and having a movable gauge at the back, and set-screw to regulate the distance of the groove from the edge of the plate. The cutter is a piece of round steel about one-sixteenth of an inch in diameter. One end is squared with a file, and into this end a recess is cut diagonally with a fine three-square file. The cutter is then placed in the instrument in a hole drilled to receive it and made fast with a set screw. Figure 11 is the neck, and 12 shows the recess in the end block for its reception. Figure 13 is a contrivance for bending the side-pieces, and 14 gives an idea of the guides used in modeling the tables of the violin.

In our next we shall have something to say about the working of the inside of the



DETAILS OF VIOLIN CONSTRUCTION.

plates, and on the proper degree of thickness which they ought to have in order to give the best results.

How to Make an Electric Bell.

FIRST, obtain at the blacksmiths' a piece of round iron about four and a half inches long and of a size that will fit the hole in a thread spool about an inch and a quarter long. Have the iron bent into a U shape as in Fig. 1, the arms of which should be about one inch and a quarter long and one inch and a half apart. Take the spools and whittle them down to a thin shell, so as to allow the wire which is to be wound around them to come as near the hole as possible. Divide your insulated wire into two equal lengths, each of which is to be wound around the spools separately. Before beginning to wind the spools drill a small hole the size of the wire through the wooden shell at one end, then insert one end of the wire, letting it project a few inches from the inside, then begin to wind the first layer, and wind neatly back and forth until all of that piece of wire is used. Wind the other spool in the same way, taking care to wind both spools in the same direction. After this is done place the spools on the arms of the U; scrape the insulating covering from the ends of the wires which were left projecting from the inside of the spools, and twist them together as in Fig. 2. This U-shaped iron with its spools of wire, will, when properly connected with the poles of the battery, form an electro-magnet, the iron being magnetic only when the coils of wire around it form the circuit of a battery.

To make the armature and bell-hammer: Take a strip of iron one inch and three-quarters long and about as thick as a ten cent piece and rivet to one end of this piece of iron a piece of clock-spring about one inch long. To the other end solder a stout piece of wire the size of a knitting-needle, four inches long, and fasten to the end of it a small knob, after which bend it into the shape shown in Fig. 3, which shows the armature and bell-hammer complete. To make the circuit-breaker: Take another piece of clock-spring an inch and a quarter long and punch a small hole in one end, into which rivet a short piece of copper wire which may afterwards be filed down to a small knob on the spring. Solder the other end of the spring under the head of a round-headed brass screw, as in Fig. 4. Next procure the bell. Any bell not exceeding six inches in diameter will answer.

To put the apparatus together and operate: Obtain a board about one inch thick, four inches wide and nine inches long. Screw the electro-magnet to the board as in Fig. 5 by a small cross-piece. Support the armature close to and opposite the ends of the electro-magnet by fastening the end of the spring to a small brass support shown at A. Screw the circuit-breaker, Fig. 4, into place at B, and bend it so that the little knob will just touch the stout wire where it is soldered to the armature. Screw the bell on at F, so that the knob will just strike the edge when the armature strikes the ends of the magnet. Paste a small strip of thin paper on the inside of the armature so it will not stick to the ends of the magnet, as the particles of steel in the iron do not lose their magnetism when the circuit is broken. *Remember that all contacts of wires and other parts through which the current is to flow must be scraped bright.* When all parts are in place, connect the wires as follows: one wire from the electro-magnet is to be led to and placed between two copper washers which are clamped together by a round-head screw, screwed into the board at D. Fasten the other wire from the magnet to the support which holds the armature at A. Then with a short bit of copper wire connect the screw which holds the circuit breaker with two more copper washers arranged to clamp the wire at E in the same way as at D. To ring the bell, clamp the wire from the positive pole of the battery, between the washers at D. Then with the wire from the other pole touch the washers at E, and if the apparatus has been properly made and adjusted the bell will ring while the connection is made. Now trace the course of the current. It

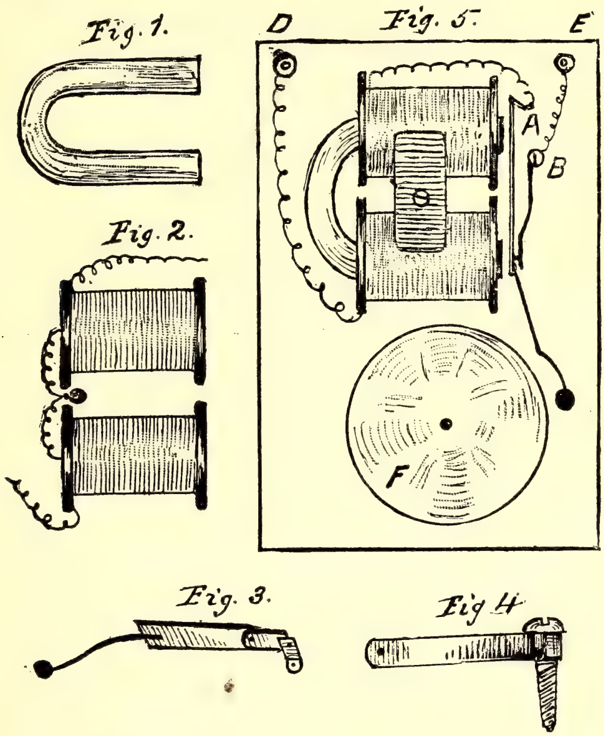
flows through the binding-screw D, then through the coils on the arms of the U, thence to A, and through the armature to circuit breaker B, and back to battery through the binding screw E. The completion of the circuit makes a magnet of the U and draws the armature to itself, and by doing so, breaks the circuit between the armature and spring B, which causes the magnet to lose its power, thus enabling the spring on the armature to return it to its normal position, which completes the circuit, and the operation is again repeated and so on, while the battery is connected. Your electric bell is now complete, and at some future time I hope to tell you of its practical uses.

GEO. THOMPSON.

Malden, Mass.

Marvels of Pond Life.—XI.

SCATTERED about Hampstead Heath are a number of little pools, not big enough to be dignified by the name of ponds. They are generally surrounded by furze bushes, and would escape attention if not actually looked for. Those which are mere puddles, and have only a brief existence in rainy weather, seldom reward the labor of investigation; but others are permanent, except after prolonged drought, and afford convenient situations for the growth of confervæ, star-weed, and other plants. These will nearly always repay the microscopic collector during the winter, when he must break the ice to get at their contents; in spring, when long chains of frog-spawn afford ocular evidence of the prolific properties of the Batrachian reptiles; and in summer, when they afford both shade and sunshine to their numerous inhabitants. Small beetles, water-spiders, larvæ of



ELECTRIC BELL.

gnats, and other insects, rotifers, including the tubicolar sorts, and several varieties of infusoria may be expected and generally found. There is, however, a curious fact about ponds, big and little, which Pritchard remarks upon in his 'Infusoria,' and which corresponds with our own experience, that those which have proved to be well stocked with any particular creature during one year, will very likely contain none of it in the next. There are of course exceptions to this rule, but we have often been astonished and disappointed at finding the complete change, both in populousness and population, that a revolution of twelve months will make; and it would be extremely interesting to notice the changes that took place during a term of years.

Such researches might unfold some unexpected laws in the succession of infusorial life. Those germs which are most widely diffused, will be the most likely to be developed in any mass of convenient water; but how and why the rarer forms come and go is very imperfectly understood. Slight modifications in surrounding circumstances will materially affect the result. Thus, if we bring home a handful of conferva, and a few water-plants of higher organization, such as duck-weed and anacharis, and place the whole in a glass jar full of pond water, we shall at first have a good stock of objects; but they will usually grow less and less, until scarcely anything is left. If, however, we introduce a few pieces of straw, or a tiny wisp of hay, we shall succeed much better, and not only preserve our population longer, but enjoy a succession of animated crops. Extensive decomposition of vegetable matter kills off all but certain families, such as Paramecia, who enjoy it; on the other hand, too little decomposition proves fatal to some creatures, by depriving them of their food, and when they have died off, those who depended upon them for a living, die too. Different vegetables in decomposition suit different creatures, and hay and straw in that state seem to please the largest number. An animalcule tank will succeed best when it contains two or three kinds of growing plants, which oxygenize the air, and a moderate variety of decomposing organisms will supply food without making the water offensive.

From these considerations it will be apparent that not only the nature of the vegetation of a pond, which is often changed by accidental circumstances, but also the quality of the odds and ends that the winds may blow into it, or which may fall through the air, will do much to determine the character and number of its inhabitants, while the quantity of shade or sunshine it enjoys, will also exercise an important influence. Hay and other infusions have from the beginning of microscopic investigations been employed to obtain the creatures which the Germans call "Infusions thierchen" (infusion animalcules), and the English "Infusoria;" but very little has yet been done in the way of their scientific culture and management.

To return from this digression to our little Hampstead ponds, we obtained from one, in September, that was full of star-weed, a number of sugar-loaf bodies, adhering to one another, and of a pale yellow brown color. The specimens first examined looked complete in themselves, and were taken for eggs of some water creature. Further search, however, disclosed aggregations of similar sugar-loaves that had evidently formed part of a tubular structure, and the idea at once occurred that they were fragments of a Melicerta tube, a conclusion that was verified by finding some tubes entire and a dead Melicerta in the rubbish at the bottom. All the specimens of Melicerta tubes we had hitherto examined were composed of *rounded* pellets, but these were made of pointed cones or sugar-loaves, with the points projecting outwards from the general surface. In Pritchard's 'Infusoria,' these pellets are described "as small lenticular bodies." The 'Micrographic Dictionary' states that the tubes of the Melicerta are composed of "numerous rounded or discoidal bodies;" and Mr. Gosse, in his 'Tenby,' which contains an admirable description, and an exquisite drawing of this interesting rotifer, calls the pellets "round."

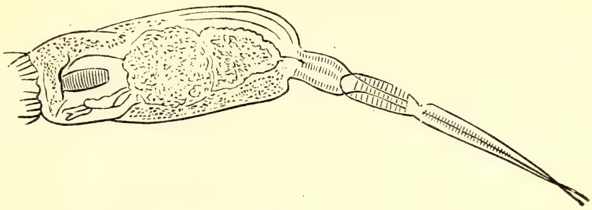
Not being able to obtain a living specimen of the Melicerta, who made her tube of long sugar-loaves, I could not tell whether she differed in structure from the usual pattern of her race, but the general appearance of the dead body was the same. It is possible that these creatures possess some power of modifying the form of their singular bricks, or they may at different ages vary the patterns, which matters some fortunate possessor of a colony of these animals may be able to verify.

In the sediment of the water containing the Melicerta cases was found an animalcule about 1-120'' long, covered with cilia, and having a proboscis seldom more than a quarter of the length assumed by the body, which continually changed its form, sometimes elongating, sometimes shortening, and often contracting one side into a deep fissure. It was, probably, an *Amphileptus*, though not precisely agreeing with any drawing or description I am acquainted with. Another inmate of the same water was a lively long-tailed rotifer, with a small oval body, a tuft of vibrating cilia and a curved bristle visible among them on one side. This creature had a

jointed tail-foot, ending in two long style-shaped toes, and by means of this appendage executed rapid leaps or springs. It was the *Scaridium longicaudum*, and agreed in dimensions tolerably well with the size given in the books, namely, total length 1-72″. With a power of five hundred diameters the muscles of the tail-foot presented a beautifully striated appearance.

susceptible of greater modification than is exhibited by the ordinary infusoria.

The Stephanoceros is a member of the Floscule family, but in all the specimens I obtained and watched for several weeks, there was an important difference in the relation of the tube to the creature. In the Floscules I had never seen anything like an adhesion between the tube and the animal, but in the Stephanoceros I noticed



200

Scaridium longicaudum.

Towards the end of the month I passed the Vale of Heath Pond, Hampstead, and although I had not gone out for the purpose of collecting, was fortunately provided with a two-dram bottle. Close by the path the *Anacharis alsinastrum* grew in profusion, quantities of water-snails crawled among its branches, and small fish darted in and out, threading their mazes with lightning rapidity. Thrusting a walking-stick among the mass of vegetation, a few little tufts were drawn up and carefully bottled, with the addition of a little water. Returning home, a few leaves were placed in the live-box, and on examination with the power of sixty diameters they disclosed a specimen of, perhaps, the most beautiful of all the rotifers, the *Stephanoceros Eichornii*. In this elegant creature an oval body, somewhat expanded at the top, is supported upon a tapering stalk, and stands in a gelatinous bottle, composed of irregular rings superimposed one upon the other, as if thrown off by successive efforts, the upper ones being inverted and attached to the body of the animal. But that which constitutes the glory of this little being is the crown of five tapering tentacles, each having two rows of long cilia arranged on opposing sides, but not in the same plane. The ordinary position of the tentacles is that of a graceful elliptical curve, first swelling outwards, then bending inwards, until their points closely approximate, but each is capable of independent motion, and they are seldom quiet for many minutes at a time. The cilia can be arranged in parallel rows or in tufts at the will of the creature, and their motion appears under control, and it continually, and always in the manner already described. Like the Floscule, the Stephanoceros is readily alarmed, and retreats into her house, carrying with her the invaginated portion. In the last edition of 'Pritchard's Infusoria,' this case is spoken of as apparently not tubular, but a solid gelatinous mass, enveloping the animal as high up as the base of the rotatory arms. It is very likely that specimens at different ages, and possibly in different seasons, may vary in the structure of their abodes; but I am not able to concur in the preceding account, as all the tubes I examined resembled sacks turned in at the mouths, and attached to the shoulders only of their inmates; and on one occasion I was able to look down into a deserted tube, which had not collapsed, as it would have done if it had been merely a solid gelatinous mass.

Like the Floscule, the Stephanoceros only reveals her beauties under careful illumination. A direct light renders them invisible, and only when the requisite obliquity has been obtained, does the exquisite character of the structure become displayed. The dark-ground illumination is very useful, and makes the ciliary action very distinct. At times a view can be obtained, in which the cilia of perhaps a single tentacle are all ranged like the steel spring of a musical box. For a moment they are quiescent, and then they vibrate in succession, each moving thread sparkling in the light. With a clumsy mode of lighting them, the cilia look like stumpy bristles, and are often so drawn; but precisely the right quantity of light coming in the right direction, makes them appear more numerous, and much longer

than would at first be supposed. When well exhibited the tentacles have a lustre between glass and pearl; the body, in a favorable specimen, is like a crystal cup, and the food, usually composed of small red and green globes, glows like emeralds and rubies, as if in the height of luxury the little epicure had more than rivalled Cleopatra's draught, and instead of dissolving, swallowed its jewelry whole. So lustrous and varied in color is the whole appearance of the animal under these circumstances, that it is frequently alluded to by one of our first artists, to whom it was displayed.

It is said by some authors that the tentacles are used to seize prey. This never occurred under my observation, although their basal portions are often approximated when an object is forced down to the grinding apparatus below. The Stephanoceros is a ravenous feeder, and swallows a variety of creatures. Green vegetable monads, rich red and brown globes of similar characters, and any animalcule that comes in her way is acceptable; and even good-sized rotifers do not escape her all-consuming maw. On one occasion I noticed one of the loricated sort, more than half as long as one of her tentacles, rapidly swallowed, and passed downwards without attempting to escape, Objects much too big for the gizzard are often gulped down, and probably receive a preliminary softening and maceration in the crop. Very often, when food is plentiful, the creature is filled to the brim, but still endeavors to continue her abundant meal. From the presence of large quantities of food and the density of the integuments, the gizzard cannot always be seen; but in favorable specimens its teeth may be observed busily at work.

At the base of the tentacles small masses of matter may be discovered, which are probably nervous ganglia and other organs; and Ehrenberg discovered small vibrating bodies, supposed to be connected with the function of respiration. A single egg, is often found, and the ovarium is said to develop but few at a time. Two red eyes are found in young specimens, but in adults they either disappear or are not conspicuous. The Stephanoceri are sociable animals, and when one is found, others are probably near at hand. Several may often be discovered on the same branch of a small water-plant, of various dimensions, and in different stages of growth. The full size is about 1-36'' in height, and from its magnitude care is required not to crush it in the live-box. When specimens are plentiful, some should be placed in that convenient receptacle; and others with the plant on which they are growing, in a glass cell or trough, where they have more room to display their motions, and can with fresh supplies of water, be preserved for days and weeks. With occasional renewals from one pond, I was able to keep up a stock for about three months, and never had objects which gave more pleasure to myself or to my friends.

Cleaning Engravings.

IT very often occurs that professional photographers have brought to them engravings to copy, and it generally happens that they are old, discolored, and stained in great patches about the color of gingerbread. Of all colors this is, photographically, most objectionable, and it is nearly impossible to obtain a passable result. If the engraving happen to be a valuable one the photographer, as a rule, is almost afraid to try and clean it, lest he should spoil it, especially with the receipts we find published in various receipt books. Only a short time ago I was looking over some of these books. One advocated chloride of lime, another hydrochloric acid, and agents of a similar nature. We all know the bleaching power of such powerful agents. With regard to the first named, I for one, always shun it, as when once it gets in to any organic material it is very difficult to eliminate it again, and it is well known that if any of the lime compounds are allowed to remain the whole fabric, in the course of time, rots and drops to pieces.

I know many amateurs who like this kind of practice in copying old engravings, and are not aware that there is a means of cleaning and restoring them without the slightest possible risk; and, moreover, the plan I am about to propose is a very inexpensive one indeed.

Staining not only occurs in old engravings, but in modern ones we very often see parts of a picture stained sometimes through a knot in the back board, or the wood of the same being full of turpentine. All these markings can be removed. My plan is to get a dish or china tray a little larger than the engraving to be operated upon; if smaller there is a great risk of tearing and damaging the engraving. The bleaching agent is no other than Holmes' ozone bleach. The strength I prefer to any other is one part of ozone bleach to ten of water, well shaken up before pouring into the dish. A much stronger solution can be used—in fact, I have used it as strong as one to five of water; but the reason I use the weaker one is that I am of the opinion that the less of the agent we use the less we have to soak out of the paper afterward. I immerse the engraving in the solution, face upward, avoiding bubbles. The only caution to be observed is that when the engraving is sodden with water it is some-

what rotten; so the less it is handled the better, though I have not the slightest fear in manipulating engravings of the largest size. Sometimes, if the engraving be only slightly stained, half an hour is quite sufficient, but when quite brown I have left them in for as long as four hours. With a stronger solution the time required is much less.

After all the stains are removed, and the paper has regained its pure whiteness, pour the solution out of the dish into a bottle (as this can be used over and over again—that is, several times until it becomes discolored, when it must be discarded), then fill up the dish with water, changing frequently for about two hours, or, better still, place it in running water. When sufficiently washed it can be taken out and blotted off, and then hung up to dry, and, when perfectly dry, I find it advisable to iron on the back with a warm flat-iron; but care must be taken not to have it too hot. When finished it will be as white as the first day it came from the press. The plan is very simple, and my advice is, try it.—*British Journal of Photography.*

Postage Stamp Frauds.

EVERY one must have noticed that periodically there comes up a demand for old postage stamps. People are asked to collect them, and various supremely silly reasons are given as excuses for the request. Now we are told that some one is going to paper a room with them, and that when the room is finished a sum equal to the value of all the stamps will be given to some benevolent institution; at other times we are told that some rich idiot has promised to educate or endow, or do some other kind thing to some young girl if she can collect a million of postage stamps. And at one time we were told that the stamps had a real value, as the mucilage, the dye-stuff used in coloring, and the paper itself all had a superior value.

It is hardly necessary to say that all these statements are false. The stamps are in almost every instance collected for fraudulent purposes. At one time certain parties made a regular business of "washing" stamps and selling them as new. Many of the stamps, however, are so slightly soiled that they can readily be used a second time without any washing. It is also said that certain rogues in the post office use these old stamps to affix to letters from which the clean stamps have been removed. In view of these well-established facts, the *Scientific American* comes to the conclusion that the inventor who can make a really serviceable postage stamp that can be readily applied to an envelope, but which cannot be removed without the total obliteration of the stamp, will have produced a valuable improvement. By a serviceable postage stamp is meant one that will bear reasonable handling without injury, that has no poisonous qualities, that is easily applied, and, as just stated, that cannot be removed intact after it is once put on the letter.

The American Institute Fair.

THE annual fair of the American Institute has been announced, and from the published plans and methods of the managers, we should say that the exhibition this fall will be the best that has been held in many years. The managers seem to have taken the advice of the best friends of the Institute, and propose to make a special feature of processes and manufactures in operation. We have always held that the Institute has a higher mission to perform than to serve as a mere bazaar for advertising and selling goods, though we have no objections to this feature provided it is kept in due subordination to the rest. The American Institute has always been one of the great educational agencies of the city, and this feature should be maintained by all legitimate effort. We are glad to see that the management takes this view of the matter, and we feel sure that both for interest, brilliancy, and instructiveness, the coming fair will be ahead of anything that has yet been held. We hope our readers will make a note of it.

—To wind a watch it is better to turn the hole downward, and let the small end of the key point upward. This will allow any little particles of dirt, metal or dust to drop out, and the watch will not need cleaning so often.

Correspondence.

The Persecution of the English Sparrows.

Ed. Young Scientist.—A most uncalled for and cruel war against the English sparrows is now in progress in almost every part of the United States. This war is based in general upon the following beliefs:

1st. That they destroy the crops.

2nd. That they drive away all birds not belonging to their own species.

The first belief is in part probably true; but if it was not for the English sparrows would the farmers have any crops to destroy? How was it in New York before the English sparrows were introduced into that city? When worms of all descriptions hung from the branches of the trees and dropped on passers by, in like manner would the farmers' crops be treated, and what little damage the English sparrows do to the farmers' crops are amply repaid by the myriads of insects, worms, etc., which they daily destroy. I was reading some time ago a piece in a paper in which the following declaration was made. I do not remember the exact words, but it was very much as follows: "The English sparrow not being an insectivorous bird in the country from which it was imported, it is hardly to be supposed that it will change to an insectiverous bird in this country." The writer of this piece must have been a fool or an idiot, as the English sparrow has already proved itself an insectivorous bird in more than one way.

We will now take the second and most ridiculous belief which a number of very well-meaning folks possess, and that is that the English sparrows drive away all other birds except its own species. This belief is both untrue and unjust. I have often seen English sparrows fighting among themselves, but very seldom have I seen them destroying birds of any other species, while it is a very common thing to see blue-birds, wrens, cat-birds, robins, etc., fighting among themselves, each species endeavoring to drive the other species away.

The following is an extract of a piece which appeared in the *Ogdensburg Journal* of May 31, 1882, and which was reprinted in the *New York Times* of June 2nd. "The sparrow is the most valuable of all birds. While breeding he feeds his young with grubs, flies, insects, bugs, and caterpillars. He is noisy and social, perhaps a little too much so. All the stories about the pugnacity of this bird are false. Any one who has observed the species enough to distinguish the sexes, will, by a little close observation, discover how much he has been deluded about the fighting sparrow." I have written this piece with the hope that the English sparrows may find more favor in the eyes of at least the readers of the YOUNG SCIENTIST.

ALEXANDER G. GIBBS.

The Parasol Ant.

A correspondent from the London *Field*, writing from the Island of Trinidad, W. I., says:

"We were about returning to the boat when one of Mr. B.'s sons, who had been some little distance away from us sauntering about in the bush, called to me to come back, and, on going to where he was, he pointed to what seemed a broad band of moving leaves right across the path, and, on looking more closely, I saw we had met with one of those enormous swarms of the 'parasol ants,' which are so destructive to plantations in the tropics.

"They were crossing from one side of the wood to the other, and were traveling in a column of more than a foot and a half in width; and as each insect carried in its mouth a piece of leaf, which entirely covered the body, they presented a singular appearance, like a Lilliputian grove in motion; and, although we watched them for some time, still they came, their numbers seeming to be inexhaustible.

"Nothing can turn them from their course; and although they be destroyed by the thousands, enough will swarm upon the intruder to make him repent interfering with them. On the mainland of South America I have known a fruit tree stripped in a single night by a swarm of these ants."

Fishing for Rats.

A novel mode of catching rats is thus described in the *American Angler*. The writer says that a person having the patience of most fishermen can have much sport in hooking the vermin.

The warehouse adjoining his place of business is infested by these "file-tails," and our friend may be seen in the early spring, and late fall, on an occasional evening just after dusk, seated at the back window of his counting room (overlooking the yard of the warehouse), with an ordinary rod in hand, strong linen line, and a spring hook, commonly called a "sockdolager," baited with a lump of fresh beef, patiently waiting for a bite. It does not tarry long nor does it consume itself in nibbles, but with a hungry snap the bait is seized and the hooks of the sockdolager impales the rat, when the excitement commences.

A lusty rat is no mean antagonist at the end

of a pliant pole and ten feet of line, and his plunges, twistings, and straight-away dashes are more perplexing to the angler than the leaps, surges, and sulkings of the gamy trout or bass. The rat is generally landed, after seasonable sport, and killed by a blow from a bludgeon.

In this connection we may state that thousands of small hooks are bought by sugar refiners for ratting purposes. The hooks are baited with small pieces of beef on each, and then distributed about the building. The rats swallow beef and hook—the first is digested, the latter is not—death of course results. The remedy is sald to be infallible.

Notes on Belting.

In putting on a belt be sure that the joints run with the pulleys, and not against them. Leather belts should be well protected against water, and even loose steam or other moisture. To obtain a greater amount of power from belts, the pulleys may be covered with leather; this will allow the belts to run very slack, and give 25 per cent. more durability. In punching a belt for lacing, it is desirable to use an oval punch, the larger diameter of the punch being parallel with the belt, so as to cut out as little of the effective section of the leather as possible. Begin to lace in the centre of the belt, and take care to keep the ends exactly in line, and to lace both sides with equal tightness; the lacing should not be crossed on the side of the belt that runs next the pulley; thin but strong laces only should be used. A careful workman will see that his belts are redressed about every four months, by sponging the dirt from them with warm soap and water, then drying with a cloth, and, while still damp, rubbing in castor oil or currier's grease, which will be readily absorbed, the leather being moist from washing. Castor oil has the additional advantage of preventing rats attacking the leather.

Practical Hints.

American Silk Culture.—The Women's Silk Culture Association has given notice of its willingness to purchase cocoons from all parts of the country. Many persons in the South and West have raised cocoons, but have been unable hitherto to find a market for their product.

Growth of Trees.—When timber planting is in order, as it most certainly will be in a few years, it will be desirable to know the rate of growth of different trees, in order to know what will grow rapidly and be serviceable in a short time. Observation tends to show that the growth for twelve years is as follows: White maple, one foot in diameter, thirty feet high; ash, one foot in diameter, twenty feet high; white willow, one and a half feet diameter, fifty feet high; yellow willow, one and a half feet diameter, thirty-five feet high; Lombardy poplar, ten inches diameter, forty feet high; blue and white ash, ten inches diameter, twenty-five feet high; black walnut and butternut, ten inches diameter and twenty feet high.

Diamantine.—Diamantine consists of crystallized boron, the basis of borax. The *Techniker* says that by melting one hundred parts boric acid and eighty parts aluminum, crystals are obtained, the so-called bort, which even attacks diamond. Diamantine bought in commerce is less hard.

Interesting Discovery.—Some fine carvings in ivory, discovered at Nineveh, showed signs of crumbling on arriving in England. Prof. Owen concluded that the decay was caused by loss of albumen in the ivory, and therefore boiled the articles in a solution of albumen. The experiment was a success, and the ivory became as firm and solid as when first entombed.

Tracings on Glass for the Lantern.—The following method, by George Smith, appears to be satisfactory. A piece of finely ground glass is rubbed over with a trace of glycerine, in order to make it as transparent as possible. It is now easy to write or draw on the prepared surface with a hard and finely pointed blacklead pencil, and the glass is so transparent that the finest details of any engraving over which it may be placed can be seen quite distinctly. The drawing having been finished, the plate is washed with water, in order to remove the glycerine, and dried. A thin coat of Canada balsam or of negative varnish now serves to render the slide permanently transparent and ready for the lantern.

Preservation of India-rubber Tubing Under Water.—Mr. Mareck relates his experience of having met with serious annual losses, in consequence of certain kinds of India-rubber tubing soon becoming brittle on exposure. After many experiments, he has adopted the plan of preserving them under water, which he renews from time to time, He found that even the thickest kind of tubing will thus remain soft and pliable without losing elasticity; nor has he found any other drawback by adopting this plan, except this, that they undergo a change in appearance. Red or brown tubing gradually fades, and becomes brownish or grayish-yellow; gray tubing becomes darker and browner externally. A section of tubing reveals the fact that about one-half of the thickness of the rubber, from the outside towards the middle, appears bleached and fatty; but the change is one which is rather of benefit for their practical use. The author adds that very thin rubber bands, with which other goods were tied, became so soft that they could be rubbed to small crumbs with the fingers.—*Dingler's Polyt. Journ.*

EXCHANGES.

Only those who are *yearly* subscribers, and whose names are entered on our books have the privilege of inserting exchanges.

Exchanges must be on separate slips of paper or postal cards. If mixed with business matter in letters or cards they are filed away and never reach the printer.

Exchanges must not exceed thirty words.

Buying and selling belong to the advertising department.

We reserve the right to omit the exchange column, when we have not room for it, and the amount of space at our disposal will regulate the number of insertions given to each *exchange*, the preference being always given to those who have not previously used our columns.

Wanted engraver's tools with book of instructions, for a Victor Press, with cabinet, 2 type cases, type, ink roller and furniture complete; perfectly new. L. Warren, 72 Cumberland St., Brooklyn, N. Y.

A Fletcher Foot-Blower, cost $5, as good as new; will exchange for a Cushman, 2 in. or up scroll chuck, or other make; will give a satisfactory trade on the difference in price, if any. Louis Lutz, St. Clair Street, Toledo, O.

I have a lot of "Galaxy" (magazines) which I would like to exchange for an air rifle in good condition, a collection of birds' eggs, or offers. W. B. Greenleaf, 480 La Salle Ave., Chicago, Ill.

I have a Mechanical Telegraph with book of instructions, books, etc., which I wish to exchange for good microscopical objects, mounted on 3 x 1 slips. Address, with list, J. H. Frey, Millersburg, Ohio.

To exchange, "How to Use Microscope," Wells' "Natural Philosophy," and many other books, chemical apparatus, etc., for good photographic camera, and lenses. W. H. Weed, 254 Putnam Ave., Brooklyn, N. Y.

Wanted "Quimby's New Bee Keeping," for "Our Own Birds of the United States," by W. S. Baily; new. Joseph Anthony, Jr., Colota, Whiteside Co., Ill.

Wanted a good book in anatomy, in exchange for a book on chemistry, or for story books. A. G. G., Box 26, Summit, New Jersey.

A German-silver trimmed, patent lined, cocoa flute, cost $4, in good order, for good spy-glass, photo-material, or offers. Ewing McLean, Greencastle, Ind.

I have some fossil shells from the west bank of the Mississippi, to exchange for Indian relics. A. W. S., 187 E. 71st St., N. Y.

I have a magic lantern, Ruby pattern, nearly new, and 5 views; also "Our First Century," bound in leather, cost $7; state what is wanted in exchange. I. N. Spencer, Box. 217, So. Manchester, Conn.

First-class telegraph instrument and attachments, and "Wood's Botany," for bound volumes of periodicals, books, or offers. H. P. Albert, Anderson, Iowa.

Wanted a book on treatment and care of canary, also breeding of same; will give in exchange book named "Market Garden, Flower Garden and Bees," or 40 "Scientific Americans" or "Seaside Libraries;" want also old books. M. J. Mulvihill, Norwalk, Conn.

Coins, minerals, stamps, books, type, fishing tackle (very complete) and fish pole, bronze inkstand, etc., for coins, medals, stamps, war envelopes, old newspapers, and Continental, Colonial and Confederate currency. F. F. Fletcher, 103 Main St., St. Johnsburg, Vt.

Blow-pipe set (cost $10), large illustrated family Bible (cost $7.50), for Wood's Botany, Dana's Geology, or printing press and type. H. W. Noble, Box 134, South Dansville, N. Y.

Wanted, offers for fossil shells from the west coast of Africa. A. W. Seward, 187 E. 71st St.

I have a number of birds' eggs I should like to trade for other birds' eggs; send for list of trading eggs. A. G. G., Box 26, Summit, New Jersey.

For a microscope stand or offers, a 36-inch turning lathe (new) and a number of scientific books; send for list. A. Kendall, Somerville, Mass.

Wanted services of amateur printer with small office (or large), in exchange for an interest in a well-established weekly paper, good size. Eagle Office, Plymouth, N. H.

American Agriculturist microscope, new, cost $15, for amateur photographic apparatus, lever watch, 22 calibre breech-loading sporting rifle or magic lantern of equal value. Wm. A. Walker, Rockland, R. I.

I. T. Bell, Franklin, Pa., has back numbers of Scientific American, Forest and Stream, and Young Scientist, good flute, chessmen, books, etc., for good magic lantern, revolver, scarce coins, or offers.

A steel spring bracket-saw, 2 doz. saw blades, and about 1 doz. patterns for a good stylographic pen or offers; send postal before exchanging. Geo. Oakley, Rutherford, N. J.

A rosewood banjo, 11 inch head, 12 nuts, fully strung, together with lot of dime banjo music and instructions, for microscope, Webster's Unabridged, monkey, squirrel and cage, or offers. J. DeWitt Clark, P. O. Box 37, Brooklyn, N. Y.

For self-inking printing press and type, one Henry rifle, 16 shot, 44 cal., cost $40, in good order, or one double barrel shot gun, barrels London fine twist, or offers. J. B. Garrison, Belton, Bell Co., Texas.

A new 40 diameter microscope, corals, and minerals, for a stylographic pen, air gun, or offers. J. McBride, 54 Garley St., Chicago.

What offers for "The Chefs D'Oeuvre D'Art, Paris Exhibition 1878," cost $16, good as new, bound; 1 large photo camera, complete, cost $95; Scientific American from 1859 to 1880, 4 vols. bound. D. Keesler, Stony Point, N. Y.

Sea shells of Atlantic coast, scientifically marked, for books, old or new magazines, Indian relics, natural history specimens, apparatus; anything. Wilfred Leon Miller, P. O. Box 392, Cape May, N. J.

A dulcimer that cost $20, books and fossils, for a telescope, microscope, fossils, Indian relics, or offers. E. J. Votaw, Salem, Iowa.

A self-inking model press, 5 x 7½, cost $23; $90 worth of scroll-saw designs in lots to suit; Scientific American, 1880; Palliser's Useful Details, $3; for photo outfit or offers. C. H. Parker, Coldbrook Springs, Mass.

Telegraph key and sounder, Frank Leslie's Illustrated Magazines, mounted microscopic objects, natural curiosities, for bull's-eye condenser, photograph camera, Unabridged Webster Dictionary, or offers. W. T. Alan, Greenville, Mercer Co., Pa.

Large magic lantern, spectroscope, pantagraph, for enlarging drawings, rosewood writing desk, man's saddle, for microscope, photo outfit or offers. Thomas Walters, Bergen St., East of Brooklyn Ave., Brooklyn, N. Y.

Model card press, chase 3¼ x 5¼, with 4 fonts type, cases, etc., for good foot lathe. Mills Day, 2 Farmington Av., Hartford, Ct.

French microscope, inclines to any angle, delicate fine motion, neat upright case, cost $17.50, for scientific books; send list to W. Fitz, P.O. Box 2852, New York.

Wanted, Quinby's New Bee Keeping, for Our Own Birds of the United States, by W. S. Baily; new. Joseph Anthony, Jr., Coleta, Whiteside Co., Illinois.

Printing type, small pica; large and small capitals, and small letters; 60 to 65 lbs., including two large cases; also gothic nonpariel, for trade. J. Siler, 1242 Broadway, St. Louis, Mo.

One years' copy of Aldine, cost $5.50, and German accordion, with instructions how to use it, cost $5.00, for offers. Chas. Dempwolf, 86 Benson St., Paterson, N. J.

A Novelty printing press, with type, prints a form 5 x 7 inches, cost $40.00, for a microscope, photographic apparatus, or offers. T. W. Patterson, Warsaw, N. Y.

$80 worth of (nearly new) printing material, minerals, fossils, Aboriginal relics, etc., for scientific books, good American watch, and offers. F. M. Farrell, Cobden, Union Co., Ills.

Rocks, minerals, fossils and fresh water shells for microscope stand, $20 to $75, also for objectives, turning lathe type, and tools. D. D. Babcock, South Dansville, N. Y.

Magic lantern, in good order, condensing lens, 2½ in. diameter, 8 slides. For small photographic camera or offers. H. A. Giddings, 4 Union Place, Classon Ave., Brooklyn.

The Young Scientist

SCIENCE IS KNOWLEDGE.

KNOWLEDGE IS POWER.

A PRACTICAL JOURNAL OF

HOME ARTS.

VOL. V. NEW YORK, AUGUST, 1882. No. 8.

Scientific Drama.

ONE of the latest attempts to popularize science consists in the presentation of a drama which embodies the history and illustrates the principles of some great scientific discovery. Figuier, so well known as a popular scientific writer, has written a historical play, in which is set forth the discovery of the steam engine, and the history of one of the early inventors, Denis Papin. From the *Industrial News* we quote the following account of this play:

"It is illustrated in eight tableaux, and the author, while adhering to correct historical data for the principal events, has interwoven such details of romance as to satisfy the supposed requirements of a drama in the matter of a plot. Papin, the learned hero, being a Protestant, is by the revocation of the edict of Nantes, by Louis XIV. compelled to leave Paris. He goes to London and marries the daughter of a rich brewer, by whom he has two children. Pursued by a never ceasing desire for scientific discovery he forsakes his wife, and taking his daughter and an old servant with him, repairs to Germany to consult with the learned men of Marburg University. In the third scene we are introduced into Papin's laboratory, where he has already spent some years endeavoring to discover a 'universal motor.' He has just tried gunpowder with only partial success, when the boiling of an iron pot full of soup suddenly turns his attention to steam. Assembling his colleagues Papin introduces a jet of steam into a long iron cylinder, and forthwith succeeds in raising a heavy weight with a man hanging on to it. He next applies his invention to a boat, and intends sailing it down the Weser and over the ocean to England. And the historical fact is here introduced that the boatmen of the Weser, fearing that their business will be interfered with by that which they call an invention of

Satan, attack and destroy the steamboat, and are only prevented by the timely arrival of some Hanoverian soldiery from murdering Papin, his daughter and a German student to whom she is betrothed. The unfortunate man returns to London where his wife has died during his absence. He is now plunged in the most abject poverty, without food. The daughter dies, after seeing for a few moments her lover, who comes from Germany with brilliant proposals to Papin from the University of Marburg. These he declines, but on hearing that a blacksmith named Newcomen is making steam engines at a place called 'Darmouth,' he goes thither, accompanied by the student Hermann and another German friend. The blacksmith turns out to be the son of Papin, who thought that the youth had perished in a fire at his grandfather's brewery some years previously. Papin does not make known his relationship to Newcomen, but assists him to construct a huge steam pump ordered by the Lord Mayor of London to provide the city with Thames water.

The final tableau shows this enormous machine, a beam engine, majestically pumping up Thames water, while the Lord Mayor, surrounded by red-coated guards, assists at the inauguration ceremony, which is enlivened by the strains of 'God Save the King.' Newcomen, who reaps all the honor of the invention, generously ascribes a share to Papin; but their mutual satisfaction is short lived. For some incomprehensible reason Papin's old enemies, the Weser boatmen, appear on the scene; they cut a rope connecting the cylinder of the engine with the beam. The machine stops working and the boiler threatens to burst. Papin gallantly breaks open the safety valve and is mortally wounded; but the machine blows up nevertheless, and amid a shower of sparks and red fire the hero sinks down dead, after disclosing his identity to his son.

It is said that the play is not a success and that it does not promise to be popular. The reason of this may be found in the attempt of the author to disguise scientific instruction too much in the garb of a novel; or it may be that the public has yet to be educated up to the point where they will as willingly go to a place where they can receive instruction, as to a place where they are merely attracted by the amusements offered. Let science be made attractive to those who are not yet elevated to the level of finding science attractive in and of itself."

Save the Flowers.

BY A. W. ROBERTS.

I HAVE often wondered, as the winter evenings draw nigh, why some of our young folks have not thought what a good thing it would be if we could take up and preserve the thousands of beautiful flowering and foliage plants that have adorned our yards all summer long, and are doomed to perish by the frost if not cared for. How many cheerless and scantily furnished homes might be made

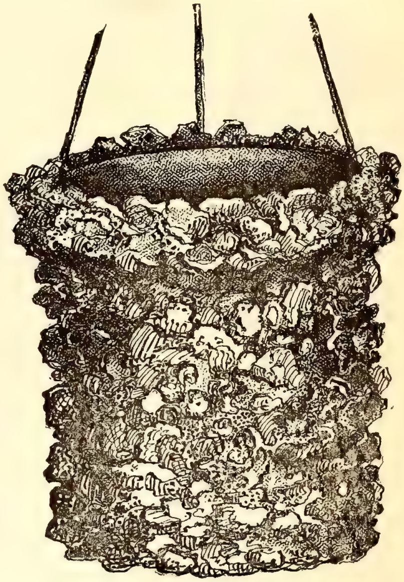


Fig. 1.

to bloom if these same flowers (which I have noticed in the large cities are in the great majority of cases left to perish) were taken up and placed in home-made or cheap earthenware pots. Then there are our numerous charitable institutions

for sick and poor children. One of the cheapest and most easily constructed of home-made flower pots, is that shown at Fig. 1, which is intended for a hanging flower pot, and is constructed out of an empty tomato or peach can. A can, when used for growing, should be thoroughly coated on the inside with asphalt varnish to save it from rusting at the joints. In this case the can is coated both on the inside and outside with asphalt varnish.

Fig. 2.

To the sides of the can clinkers are fastened by means of melted asphalt (such as is used for roofing). These clinkers can be obtained of various shapes and colors from the furnaces of engine rooms or glass houses. It is best to avoid what is known as "slag," that is produced in iron foundries, as it is a very heavy material, and is apt to become rusty in course of time. As will be seen by the figure, the clinkers attached to the rim of the can are much larger in size, and project beyond those on the body of the can. This is done to break up the otherwise stiff uniformity of the outline. It must be borne in mind that without the outside coating of asphalt varnish it is almost impossible to attach the clinkers to the can, as the hard asphalt when applied to the tin of the can will not adhere to it. In case the clinkers do not appear brilliant enough in color, they can be touched up here and there with cheap oil colors. When plants are very large it is always best to make use of cuttings. Much that is of interest in plant life may be learned from the starting point of a rose or geranium slip or cutting, how the "callous" is first formed, and its gradual development into roots, and how, when a sufficient number of rootlets are at work supplying and conveying food for the cutting, the leaf buds begin to unfold and develop into leaves, and so on till the

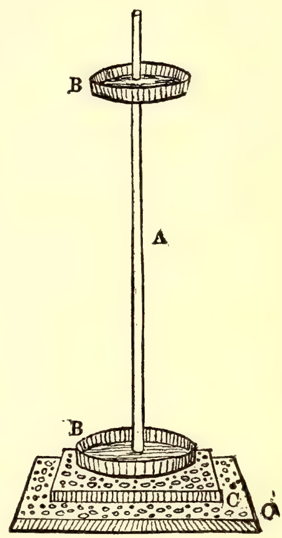

Fig. 3.

flower buds and perfect flowers appear. When shifting flowers from the garden to indoors it is always best to allow them to "season off" for a few days before introducing them into a room.

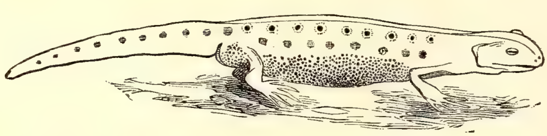
I have always found pots containing living plants and flowers very useful as a

means of ornamentation when placed in picturesque masses and groups at winter evening gatherings of children or children's parties. When mosses and berries and fern leaves are obtainable from the woods, nothing can be more elevating and pleasing than the floral effects that can be obtained at a small outlay of money and taste. On the tea or supper table at a winter's entertainment, I believe in a lavish use of both cultivated and wild floral material.

As a simple, cheap, and easily made central ornament for a table, I can highly recommend the one shown at Fig. 2. The upright, A, Fig. 3, consists of a stout glass rod, either solid or hollow, which can be obtained of manufacturers of glass chemical apparatus, also of thermometer makers, or dealers in glass birds' eyes and fancy glass goods. This rod is twenty-four inches high. The top and bottom pans consist of fruit cans cut down to the depth of two inches. In the bottoms of these pans a hole is punched, through which the glass rod passes. When a glass rod is not obtainable, a rustic upright one can be used. In some respects I prefer it to a glass one, on account of its durability and less likelihood to breakage. When using a rustic upright, always select a wood that has strong character, either of color or bark. It is entirely correct to attach small fungi, lichens, insects of brilliant colors, or butterflies. The upper end of the rod extends above the pan a distance of six inches, and is for the purpose of fastening the heavier fronds of ferns, etc., to it with fine thread. The lower end of the rod passes through two pieces of board, C C. After the rod is in position, the pans are cemented to the rod by pouring hot asphalt about the holes in the pans where the rod passes through; this is done for the purpose of making the pans water-tight. Hot asphalt is also used where the end of the rod passes through the two boards. The pans are filled with damp moss, in which the vines, ferns and flowers are placed. Small and large holes are bored into the two boards; into these holes damp moss or sand is also placed, and flowers, etc., are inserted. To prevent the wood work of the stand from warping or decaying, two or three heavy coats of a light-green paint must be applied.

Newts for the Aquarium.

WATER lizards, newts or tritons are the common names by which the animal shown in our engraving is called by the different dealers. *Triton millepunctatus* is the most common species of newt in North America. They are to be found in every clear pond, and more particularly in those ponds containing aquatic vegetation. They are perfectly harmless, and since the introduction of aquaria as a home adornment, the great prejudice that at first existed against them has nearly passed away. The newt, like other reptiles, casts his skin and goes through no less than nine different stages of being from the time of his first appearance from the egg to the end of his life mission. They feed upon earth worms and minute aquatic insects, and as they enjoy a gambol on dry land as well as in the water, the tank in which they are kept should be so arranged that they can leave the water to enjoy an air bath. This is easily accomplished by piling a few rocks above the surface of the water, and, if the position of the aquarium will allow it, the top of these rocks should be so arranged



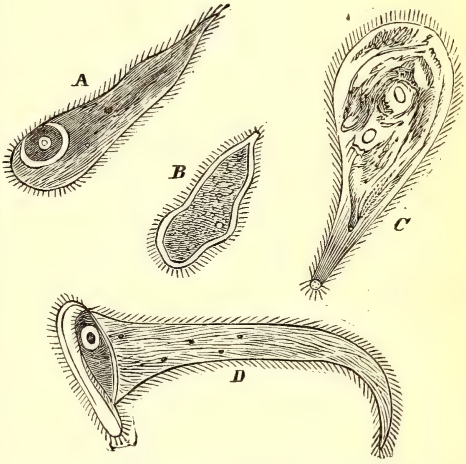
TRITON MILLEPUNCTATUS.

that the sun's rays may occasionally strike it, for a sun bath as well as an air bath is a great luxury to all aquatic reptiles. At the same time great care must be taken not to allow the newts to escape, which they will undoubtedly try to do, and as they never succeed in finding their way back, they die a lingering and miserable death. A glass frame, with walls about five inches high, confines them effectually. This frame need not be water tight, but no rough framework should present a foothold for the reptiles, and no overhanging leaves of lilies or other water plants should afford them the means of dropping over the sides.

Marvels of Pond Life.—XII.

OCTOBER, the finest of our autumn months, is noted for usually granting the inhabitants of our dripping climate about twenty pleasant sunshiny days, and it is probably on this account somewhat of a favorite with the infusorial world, although the cold of its nights and early mornings thins their numbers, which reach a maximum in the summer heat. Even in the dismal year 1860, October maintained its character, and afforded a great many opportunities of animalcule hunting, during which a constant supply of Stephanoceri were readily obtained, together with swarms of *Stentors*, which are not exceeded in interest by any of the Ciliated Protozoa. The Stentors were abundant on the same weed (*Anacharis*), that formed the residence of the Stephanoceri, and might be seen in large numbers hanging from it like green trumpets, visible to the unassisted eye. In the 'Micrographic Dictionary' they are said to belong to the Vorticella family, which has already given us several beautiful objects and possess a marvellous power of changing their shape. It is, however, better to follow Stein, who separates them from the Vorticellids and ranges them in his order Heterotricha, as they have two distinct sets of cilia, small ones covering the body and the larger ones round the mouth. Those before us are named after this property *Stentor polymorphus*, or Many-shaped Stentors, and owe their exquisite tint to numberless green vesicles, or small cavities filled with coloring matter like that of plants. This, however, is not essential to the species which may often be found of other hues. In size this Stentor varies from a hundred and twentieth to one twenty-fourth of an inch. It is entirely covered with fine cilia disposed in longitudinal rows, and round the head is a spiral wreath of larger and very conspicuous cilia leading to the mouth.

Having observed the abundance of these creatures, a few small branches to which they were appended, were placed in the glass trough, and viewed with powers of sixty and one hundred linear. Some had tumbled down as shapeless lumps, others presented broad funnel-shaped bodies; while others stretched themselves to great length like the long, narrow post-horns which still wake the echoes of a few old-fashioned towns. The ciliary motion of the elegant wreath was active and rapid, causing quite a stir among all the litttle particles, alive and dead; and when the right sort of food came near the corkscrew entrance to the mouth, down it went, and if conspicuous for color, was subsequently seen apparently embedded in little cavities, which Ehrenberg supposed were separate stomachs, although that theory is now rejected. One advantage of viewing these objects in a sufficient quantity of water,



A, B, C, D, Stentor polymorphus in different degrees of expansion. A large specimen is one twenty-fourth of an inch long.

to leave them in freedom, is that they frequently turn themselves, so that you can see right down into them. To make out the details of their structure, to see the nucleus and other organs, the flattening in the live-box is useful, and it enables much higher powers to be employed.

After leaving the Anacharis in a glass jar for a few days, the Stentors multiplied exceedingly; some clung to the sides of the vessel in sociable communities, others hung from the surface of the water, and crowds settled upon the stems, visibly changing their tint, as the Stentor green was much bluer than that of the plant.

Scores swam about in all sorts of forms. Now they looked like cylindrical vessels with expanding brims, now globular, now oddly distorted, until all semblance of the original shape was lost. Many were found in shiny tubes, but these were never so lively or green as the free swimmers, but mostly of a dingy dirty hue.

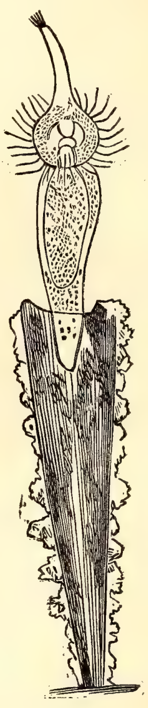
These housekeepers were more timid and cautious than the roving tribe. They came slowly out of their dens, drew back at the slightest alarm, never took their tails from home, and only extended their full length when certain not to be disturbed. Some authors have thought they only take to private lodgings when they feel a little bit poorly, but others dispute this opinion, and I do not think it is correct. I have found these Stentors at all seasons, from January to the autumn, but they are never so numerous, nor aggregated in numbers like the roving sort. Whether they are old folks, who are tired of the world and its gaieties, and devote the remainder of their lives to contemplation, or whether they are bachelors disappointed in love, I am unable to say; but they are very inferior in beauty to the "gay and glittering crowd."*

For some weeks my Stentors abounded, and then most of them suddenly disappeared. They could not have "moved," but probably "went to smash" by a process peculiar to infusoria, and which Dujardin politely describes as "diffluence." This mode of making an exit from the stage of life is more tragical than the ripping up so fashionable in Japan. The integument bursts, and its contents disperse in minute particles, that in their turn disappear, and scarcely leave a "wrack behind."

The Stentors obey the injunction to "increase and multiply" by self-division, which Stein says is always oblique, and the nucleus, which plays such an important part in infusoria, is band-like, moniliform (bead-shape), or round. When an animalcule increases by self-division, a portion of the nucleus goes with each part, and it is probably the organ which stimulates the change. It is also concerned in other modes of propagation. "The anus is situated on the back, close beneath the ciliary circle;" and the "contractile vesicle on a level with the ciliary wreath." Stein records that in November, 1858, he met green Stentors (*Polymorphus*) encysted, and he figures one in a gelatinous flask having a stopper in its narrow neck.

Before closing our account of the Stentor, let us revert a moment to the ciliary wreath, as it may be made the subject of a curious experiment. If, for example, the cilia are viewed at right-angles to their length, they will seem to form a delicate frill, in which a quivering motion is perceived. But if the table is shaken by a sharp blow, the frill is thrown into waves, or takes the form which washerwomen give to certain articles of female apparel by the use of the Italian iron, and the ciliary motion is thus made to take place in different planes, and rendered strikingly apparent.

One day turning over the Anacharis in search of subjects, a small brown tube was noticed, from which a glassy rod protruded like the feeler of a rotifer. Keeping the table quiet, and watching the result, was soon rewarded by a further protrusion of the feeler, accompanied by a portion of the body of the inmate of the tube. The feeler was thrust on this side and on that, as if collecting information for its proprietor, who, I suppose, was satisfied with the intelligence, and gradually extended herself, until she stood out two-thirds in length beyond the tube, and set two lobes of one nearly continuous ciliary organ in rapid motion. Sometimes the creature, *Cepha-*



× 180.

Cephalosiphon limnias.

* Stein says the colorless variety of S. Polymorphus is sometimes found with a tube, and the S. Rossellii very frequently so provided.

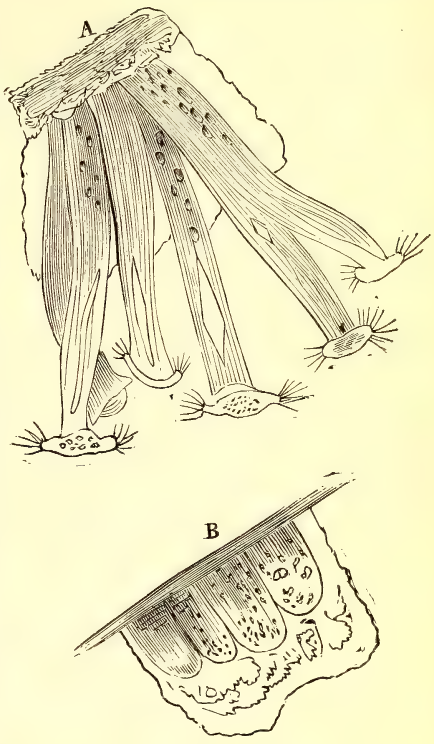
losiphon limnias, bent its neck, if I may so speak, to the right, and sometimes to the left, and sometimes stood upright, when the true form of the ciliary apparatus could be seen. The tube of this creature was opaque, from the adhesion of foreign matter, and presented an untidy appearance, strangely contrasting with the clear, neat bottles of the Floscules. These Cephalosiphons are very whimsical in their ways, and many that were sent to different observers never exhibited their ciliary wreaths, but performed sundry antics, disguising their true shape.

Somewhat like the Cephalosiphon, though much commoner and without the siphon, is Limnias ceratophylli, which every collector is sure to meet. The length of the Limnias varies, according to Pritchard, from 1-20′′ to 1-40′′. Our Cephalosiphon, when fully extended and magnified one hundred and eighty linear, looked about three inches and a half long, and was therefore very small. Just below the ciliary lobes the gizzard was seen, with its toothed hammers working one against the other. The masticatory organ differs from the typical form, as represented in the Brachion; and Mr. Gosse observes of Limnias that "each *uncus* forms, with its *ramus*, a well-defined mass of muscle enclosing the solid parts, and in form approaching the quadrature of a globe. Across the upper surface of the mass the *uncus* is stretched like three long parallel fingers, arched in their common direction, and imbedded in the muscular substances, their points just reaching the opposing face of the *ramus*, and meeting the points of the opposite *uncus* when closed."*

There is no connection between Limnias or Cephalosiphon and their tubes, except that of simple adhesion, which takes place by means of the end of their foot-stalks.

In a former article we have described an interesting relation of the Vorticella, the Cothurnia, whose elegant crystal vases form a very artistic abode, characterized by possessing a distinct foot. Other species of the same family inhabit vases which have no foot or stalk, or live in gelatinous sheaths less accurately fashioned. Sometimes these creatures are obliging enough to conform to the specific descriptions which eminent naturalists have given of them, and also to the characters which the authorities have assigned to the different genera in which they have been grouped, but the microscopist will often meet with difficulties in the way of classification.

Attached to a piece of weed were a number of cylindrical masses of brownish jelly, with rounded tops, and situated in an irregular and very transparent sheath, about twice as high as themselves. Presently they all rose up to four times their previous height, put forth a beautiful crown of vibrating cilia, and opened a



× 240.

Vaginicola (?) (A, elongated; B, retracted).

sort of trap-door to their internal arrangements. In this position they had a long cylindrical form, gracefully curved; but of nearly equal width from the mouth to the base, and they readily imbibed particles of carmine, which tinged sundry little cavities with its characteristic hue. The slightest disturbance caused the ciliary wreaths to be drawn in, and the bodies to be retracted, and descend into their house like a conjuring toy, until the appearance first described was reproduced.

The general form and structure of these objects was like the drawings usually given of *Vaginicola*, which is said not to exist in groups, although two individuals are commonly found in one well-shaped cell. These creatures, however, did not taper towards the base as Vagini-

* The term *uncus*, *ramus*, etc., have been explained in a former number.

colæ generally do, and perhaps they became aware of this defect in their figures, for after a day or two a change appeared, and they assumed a more graceful form by swelling out in the middle, and then growing slender down to the bottom, very much like the pattern given by glass-blowers to little vases of flowers.

It is very important to note the changing appearance of animalcules, and where the same individuals can be observed from day to day, these will often be found considerable. It is probable that when such particulars are fully known, the number of species will be greatly reduced, and the study of these organisms considerably simplified. I have called the animals just described *Vaginicolæ*, but the reader must be prepared to find similar bodies, inhabiting well-formed vases, either solitarily or in couples, the latter condition arising from the fission of one individual without a corresponding division of the abode.

For a few weeks I continually met with groups living as I have described, in what may be called amorphous cells, which were often so nearly like the surrounding water in refracting power, as to be discerned with some difficulty. No trace could be seen of divisions into separate cells, but they all appeared to live happily together in one room, and if one went up all went up, and if one went down all went down, as if their proceedings were regulated by a community of sensation or will.

Another little curiosity was a transparent cup upon a slender stem, which stood upright like a wine-glass, and supported on its mouth a transparent globe. By removing a leaf which prevented the stalk being traced to its termination, it was found to be a Vorticella, and after two hours the globe was partially drawn in, and reduced in size. Why the creature was engaged in blowing this bubble I do not know, and have not met with another instance of such conduct.

Executing Criminals by Electricty.

THE adoption of electricity as a mode of capital punishment has enthusiastic advocates in Germany, as well as in France, as witness the following imposing description of a method proposed by a German writer: "In a dark room, draped with black, and which is lighted only by a single torch—the chamber of execution—there shall stand an iron image of Justice with her scales and sword. Stern Justice is popularly supposed to have no bowels, but this German goddess will carry a powerful electric battery in her inside; and this battery will be connected with an arm-chair—the seat of death. In front of the chair shall stand the judge's tribunal, and only the judge, jury and other officers shall be present with the criminal during the ceremony of the execution. This will consist in the judge reading the story of the crime committed by the prisoner, who will be rigidly manacled to the aforesaid arm-chair, and when this is done, the judge will break his rod of office and toss it into one of the scale-pans of Justice, at the same time extinguishing the solitary torch. The descent of the pan will complete the electric circuit, and shock the victim into the next world."—*Iron.*

Non-Poisonous Pharaoh's Serpents.

IT is well known that the ordinary Pharaoh's serpents are exceedingly poisonous, not only in the form of powder, but from the vapors which they give off when burned.

Dr. Puscher gives the following directions for preparing Pharaoh's serpents, that are not attended with injurious fumes: Mix intimately two parts of bichromate of potassa, one part of nitrate of potassa, and three parts of white sugar. This mixture should be pressed in paper or tinfoil cones, and, if intended to be kept for any length of time, the paper should be varnished over with sandarac varnish. A small quantity of balsam of Peru may be added to perfume the mixture, so as to cause its combustion to be attended with a pleasant odor. The greenish-colored very porous mass, which assumes the serpent shape, is a mixture of carbonate of potassa, oxide of chromium, carbon, and a small quantity of neutral chromate of potassa. The author states that this mass is an excellent substance for polishing all kinds of metals, and may be, moreover, usefully employed as an absorbent for moisture, instead of chloride of calcium, since, without becoming pasty, it absorbs, in twenty-four hours, about twenty per cent. of moisture. The mixture above specified should be kept in a dark place. We have seen this mixture tested with very excellent results.

A Curious Feat.

PROFESSOR COLLADON, of Geneva, recently described a curious and little-known experiment, showing the great resistance which the air, under certain circumstances, offers to the motion of bullets in guns. It resembles a feat that was sometimes performed by soldiers with the old Swiss carbines. M. Colladon fully charged with compressed air the hollow iron breech of an air-gun, which served as a reservoir. The barrel being then screwed on, he introduced a

round lead ball, running freely, but nearly filling the bore; then, placing the gun vertical, he seized the upper end and pressed his thumb forcibly on the mouth. The gun was then "fired" by an assistant; the thumb remained in position, and the ball was heard to fall back in the bore. Thereupon, after recharging the weapon with the same ball, he shot the latter at a pine board about 1 inch thick or a pane of glass, and it passed through. The experiment, M. Colladon says, is without danger, if the operator is quite sure of the strength of his thumb, if the gun is more than 32 in. long, and if the ball is spherical, and nearly fills the gun, in which it must act like a piston.

Nature's Dressing for a Wound.

A FEW years since, while standing in the shade during the heat of the day, a toad hopped along at my feet and attracted my attention from having what appeared to be a very large forearm. Stooping down, I found that from the shoulder to the elbow-joint the fore-leg was encased in earth, which was very smooth, dry and hard. Inquisitiveness being well developed, I had, of course, a natural inclination to see what was inside, so holding "toady," with a piece of stick I broke the crust of hardened mud, and found, to my surprise, a large flesh wound extending from the shoulder to the elbow, half of the muscle being bruised and raw. From the smoothness of the work, I judged the dressing had been made from dry earth and the spittle of the toad, as it would be seemingly impossible for it to handle mud and apply it in such a manner.

I thought nothing more of the matter for a year or more, until one night one of my children retired with a very sore toe from some unknown cause, and about midnight was wild and restless with pain. I arose and opened the ulcerated part, and afforded him relief for the time being; but the pain returned, and by the next hour he was as restless as ever. After trying to give relief in various ways I thought of the toad, and, taking an old stocking, I put some mud, made of clay and water, into the toe part, and drew it on the child's foot. In 10 minutes he was asleep, and slept well the remainder of the night, and in the morning the toe appeared nearly well.

I have found that a mixture of earth and spittle is preferable, and I have used it since upon every occasion where remedies are necessary for the relief of ulcers or healing flesh wounds, and prefer it to any ointment or liniment that I have ever seen or made during many year's experience as a druggist.—*Correspondent of Phrenological Journal.*

The Effect of Printer's "Display."

A CURIOUS case came under the notice of the English inspectors of explosions of a quantity of honey which was imported into England in packages, bearing a label which, at first sight, conveyed the impresion that they contained dynamite, and a good deal of alarm was excited, and the attention of the Lord Mayor was called to the circumstance that cases containing apparently a dangerous explosive were being conveyed about London. However, on investigation it appeared that the honey was in the comb, inside boxes, the tops and bottoms of which consisted of thin sheets of glass, and several of these were enclosed in a large outer package. It was, of course, necessary that the packages should be very carefully handled, and in order to secure this the importers had had recourse to the extraordinary device of placing upon each package the label: "Handle gently as dynamite. A drop of one inch will cause certain destruction to the contents." The words "handle gently," "dynamite" and "certain destruction" being printed in much more prominent type than the rest, the label presented the appearance described. As the use of a label of this sort did not constitute an offence agaist the explosives act, the inspectors did not further concern themselves in the matter.

To Bleach Bones and Skeletons.

BONES may be bleached in several ways, though, in the main, the methods do not differ very much from each other. In the first place, it is necessary to get rid of all extraneous matter, such as attachment of ligaments, muscles, etc. Next they may be laid for several months in cold water, after which they should be boiled with weak lye. Instead of macerating them in cold water, they may be treated with lye at once, but it is not so easy to get rid of the fatty matter in this manner. Some others do not use potash at all; but, after having boiled the bones in water, they dry them, and then place them in naphtha for several weeks. After the fat has been extracted, they are generally white enough for all ordinary purposes. Still, they may be rendered whiter by immersing them for about twelve hours in a moderately dilute solution of chloride of lime (1 part of chloride of lime mixed with 50 parts of water, and strained). Finally the bones must be washed with water until the latter has completely exhausted every trace of chemicals or solvents employed on them. All bones do not stand treatment with potash equally well; the more slender, frail, and flexible a bone,

the less potash it will bear. In fact, tender bones should be bleached without this agent.

Observatory on Mount Etna.

THE following forms part of an account of this observatory, given by Signor Tedeschi: The observatory is built on a little eminence, on the side of the central crater of Etna, a position which makes it almost certain that should a stream of lava issue on that side, it would divide into two streams, and flow harmlessly on each side of the little hill. The building consists of two stories, the joint height of which is nine metres, and the base of the edifice occupies a superficial area of 200 square metres. In each story there is a circular room surrounded by other chambers destined for different uses. In the centre of the circular room in the lower story there is a solid pillar to support the great refractors. All the instruments, as well as a fine collection of seismographic and meteorological apparatus, are in the upper story, in the large circular room of which are the telescope and chronometrical apparatus. This room is roofed with a movable iron cupola. In this story are also the rooms for foreign visitors, and a little terrace, from which there is a view of half Sicily, Malta, the Lipari islands, and part of Calabria. The observatory on Etna is the highest building in Europe. The observatory on Vesuvius is 619 metres above the level of the sea, the Hospice of the Gotthardt, 2,075 metres, and that of St. Bernard 2,491; while the Etna observatory is at the height of 2,942 metres. At this great elevation there is no fear, in taking astronomical and spectroscopic observations, of the perturbations proceeding from the variable density of the different atmospheric strata, so that this observatory will probably render invaluable service to astronomical science and terrestrial physics.

Sound.

The following curious observations of sound have been carefully verified by an extended series of experiments: The whistle of a locomotive is heard 3,300 yards; the noise of a railroad train, 2,800; the report of a musket and the bark of a dog, 1,800; an orchestra or the roll of a drum, 1,600; the human voice reaches to a distance of 1,000; the croaking of frogs, 900; the chirping of crickets, 800. Distinct speaking is heard in the air from below up to a distance of 600 yards; from above, it is only understood to a range of 100 yards downwards. It has been ascertained that an echo is well reflected from the surface of smooth water only when the voice comes from an elevation. Other similar phenomena connected with the transmission of sound have been observed, but the results disagree, either from inaccuracy in the observations or from the varying nature of the circumstances affecting the numbers obtained. Such variations occur to an extent of 10 to 20 per cent., and even more. The weather being cold and dry, or warm and wet, are the chief influencing causes. In the first case the sound goes to a greater, and in the second to a lesser distance.

Seeing and Signaling.

M. Charpentier tells us that the time elapsing between a person seeing a signal and being able to repeat it with his forefinger is about thirteen-hundredths of a second. With some people the interval is twice as long, but the above may be taken as the average. M. Charpentier terms the interval in question the "duration of luminous perception," and he measures it in a very ingenious manner. A black disk is set revolving at a given speed, and the observer faces it, having under his finger an electric key. There is a small opening or window in one part of the disk, and when this comes round opposite the observer he sees a light shining through it. Immediately he presses the key and an electric signal passes to the revolving disk. The disk is stopped, and the distance between the window and the record of the signal being measured furnishes the result. The distance between the two points on the disk is, of course, easily turned into time, since the disk was revolving at a known speed.

Minute Workmanship.

The Salem Museum, Massachusetts, has in its possession a cherry stone containing one dozen spoons. The stone is of the ordinary size, the spoons being so small that their shape and finish can be distinguished only by the microscope. This is the result of immense labor for no decidedly useful purpose, and there are numbers of other objects in existence the value of which may be said to be quite as indifferent. Thus, Dr. Oliver gives an account of a cherry stone on which were carved one hundred and twenty-four heads so distinctly that the naked eye could distinguish those belonging to popes and kings by their mitres and crowns. A Nuremberg top maker inclosed in a cherry stone which was exhibited at the French Crystal Palace, a plan of Sebastopol, a railway station, and the "Messiah" of Klopstock. Pliny, too, mentions the fact that Homer's Iliad, with its 15,000 verses, was written in so small a space as to be contained in a nutshell. The greatest

curiosity of all, however, was a copy of the Bible, written by one Peter Bales, a chancery clerk, in so small a book that it could be inclosed within the shell of an English walnut. A steam-engine which can be covered by an ordinary thimble has been constructed by an American watchmaker named Beck. Its height is only sixteen millimetres, and the space it occupies is less than three square centimetres. Its weight is one gramme. It has no fewer than 140 distinct pieces connected by means of 102 screws, yet the little machine works perfectly.

Polishing Wood-Work.

Soft woods may be turned so smooth as to require no other polish than that which can be given by holding fine shavings of the same wood against them in the lathe. For polishing mahogany, walnut and some other woods, the following formula is given: Dissolve beeswax by heat in spirits of turpentine until the mixture becomes viscid. Apply with a clean cloth, and rub thoroughly with another piece of cloth. Beeswax is sometimes alone used. For work in position, it must be melted and applied and rubbed as above. For work in the lathe, it can be applied by friction, the slight amount of wax melted being sufficient for the polish. The work should be thoroughly rubbed. Mahogany may be polished by rubbing first with linseed oil, and then by a cloth dipped in very fine brick dust. Some hard woods have a natural polish, and do not require a polishing medium. A fine gloss can be produced by rubbing with linseed oil, and then holding shavings or turnings of the same material against the work in the lathe. A very perfect surface can be obtained with glass paper, which, if followed by hard rubbing, will give a beautiful lustre. Lustre can also be given to carefully finished surfaces by applying a small quantity of thinned varnish, shellac or "fillers" by a cloth, and carefully and thoroughly rubbing.—*Comstock's "Interior and Interior Details."*

Practical Hints.

Electric Wire Covering.—M. Geoffroy, a wire manufacturer in Paris, has taken a patent for covering electric wires with asbestos. Experiments, which will be repeated officially, have proved that the copper can be burned without any spark being conducted outside.

Archimedes.—Archimedes said: "Give me whereon I may stand, and I will move the universe!" Ferguson, the celebrated astronomer, was accustomed to amuse himself by calculating that if, at that moment when Archimedes pronounced these words, God had taken him at his word, in furnishing him with a standpoint at the distance of 9,000 miles from the centre of the earth, with materials of sufficient strength, and a counterpoise of 200 lbs., this great geometrician would have required a lever of twelve quadrillions of miles—12,000,000,000,000,000—and a velocity at the extremity of the long arm equal to that of a cannon ball, to raise the earth one inch in 2,700,000,000 000 years.

Aluminium Silver.—Is made by melting together one part of silver with three or four of aluminium, and is very valuable for articles in which one of the main objects is to obtain lightness, such as the instruments used for marine observations. Octants and sextants of this alloy have been received with great favor by practical navigators. Those parts of such instruments which, if made with other metal, would weigh four pounds, will, when made of the above alloy, only weigh one pound. Mechanics like to work this alloy, as it can be turned and filed away, which is not the case with the pure aluminium which is too soft, and, as no doubt all know who have worked this interesting metal, it has the objectionable property of sticking to the file.

Absorbtion of Metal by Tin.—When an alloy of lead, tin, or other metal is made with sodium in a melting pot, great care must be used in subsequently freeing the melting pot of every trace of sodium before using it for melting tin in with a view of tinning copper or bronze articles, otherwise these articles when placed in the melted tin will be rapidly eaten away. This has been recently proved by accident, but it might have been expected from known facts concerning sodium alloys, which were long ago pointed out by Mr. Mallet, who showed, among other things, that if a strip of iron be coated with sodium amalgam and dipped into a pot of say molten tin, the iron will disappear faster than it can be put to the bottom of the pot.

EXCHANGES.

Only those who are *yearly* subscribers, and whose names are entered on our books have the privilege of inserting exchanges.

Exchanges must be on separate slips of paper or postal cards. If mixed with business matter in letters or cards they are filed away and never reach the printer.

Exchanges must not exceed thirty words.

Buying and selling belong to the advertising department. We reserve the right to omit the exchange column, when we have not room for it, and the amount of space at our disposal will regulate the number of insertions given to each *exchange*, the preference being always given to those who have not previously used our columns.

Wanted engraver's tools with book of instructions, for a Victor Press, with cabinet, 2 type cases, type, ink roller and furniture complete; perfectly new. L. Warren, 72 Cumberland St., Brooklyn, N. Y.

A Fletcher Foot-Blower, cost $5, as good as new; will exchange for a Cushman, 2 in. or up scroll chuck, or other make; will give a satisfactory trade on the difference in price, if any. Louis Lutz, St. Clair Street, Toledo, O.

I have a lot of "Galaxy" (magazines) which I would like to exchange for an air rifle in good condition, a collection of birds' eggs, or offers. W. B. Greenleaf, 480 La Salle Ave., Chicago, Ill

I have a Mechanical Telegraph with book of instructions, books, etc., which I wish to exchange for good microscopical objects, mounted on 3 x 1 slips. Address, with list, J. H. Frey, Millersburg, Ohio.

To exchange, "How to Use Microscope," Wells' "Natural Philosophy," and many other books, chemical apparatus, etc., for good photographic camera, and lenses. W. H. Weed, 254 Putnam Ave., Brooklyn, N. Y.

Wanted "Quimby's New Bee Keeping," for "Our Own Birds of the United States," by W. S. Baily new. Joseph Anthony, Jr., Colota, Whiteside Co., Ill.

Wanted a good book in anatomy, in exchange for a book on chemistry, or for story books. A. G. G., Box 26, Summit, New Jersey.

A German-silver trimmed, patent lined, cocoa flute, cost $4, in good order, for good spy-glass, photo-material, or offers. Ewing McLean, Greencastle, Ind.

I have some fossil shells from the west bank of the Mississippi, to exchange for Indian relics. A. W. S., 187 E. 71st St., N. Y.

I have a magic lantern, Ruby pattern, nearly new, and 5 views; also "Our First Century," bound in leather, cost $7; state what is wanted in exchange. I. N. Spencer, Box. 217, So. Manchester, Conn.

First-class telegraph instrument and attachments, and "Wood's Botany," for bound volumes of periodicals, books, or offers. H. P. Albert, Anderson, Iowa.

Wanted a book on treatment and care of canary, also breeding of same; will give in exchange book named "Market Garden, Flower Garden and Bees," or 40 "Scientific Americans" or "Seaside Libraries;" want also old books. M. J. Mulvihill, Norwalk, Conn.

Coins, minerals, stamps, books, type, fishing tackle (very complete) and fish pole, bronze inkstand, etc., for coins, medals, stamps, war envelopes, old newspapers, and Continental, Colonial and Confederate currency. F. F. Fletcher, 103 Main St., St. Johnsburg, Vt.

Blow-pipe set (cost $10), large illustrated family Bible (cost $7.50), for Wood's Botany, Dana's Geology, or printing press and type. H. W. Noble, Box 134, South Dansville, N. Y.

Wanted, offers for fossil shells from the west coast of Africa. A. W. Seward, 187 E. 71st St.

I have a number of birds' eggs I should like to trade for other birds' eggs; send for list of trading eggs. A. G. G., Box 26, Summit, New Jersey.

For a microscope stand or offers, a 36-inch turning lathe (new) and a number of scientific books; send for list. A. Kendall, Somerville, Mass.

Wanted services of amateur printer with small office (or large), in exchange for an interest in a well-established weekly paper, good size. Eagle Office, Plymouth, N. H.

American Agriculturist microscope, new, cost $15, for amateur photographic apparatus, lever watch, 22 calibre breech-loading sporting rifle or magic lantern of equal value. Wm. A. Walker, Rockland, R. I.

I. T. Bell, Franklin, Pa., has back numbers of Scientific American, Forest and Stream, and Young Scientist, good flute, chessmen, books, etc., for good magic lantern, revolver, scarce coins, or offers.

A steel spring bracket-saw, 2 doz. saw blades, and about 1 doz. patterns for a good stylographic pen or offers; send postal before exchanging. Geo. Oakley, Rutherford, N. J.

A rosewood banjo, 11 inch head, 12 nuts, fully strung, together with lot of dime banjo music and instructions, for microscope, Webster's Unabridged, monkey, squirrel and cage, or offers. J. DeWitt Clark, P. O. Box 37, Brooklyn, N. Y.

For self-inking printing press and type, one Henry rifle, 16 shot, 44 cal., cost $40, in good order, or one double barrel shot gun, barrels London fine twist, or offers. J. B. Garrison, Belton, Bell Co., Texas.

What offers for "The Chefs D'Oeuvre D'Art, Paris Exhibition 1878," cost $16, good as new, bound; 1 large photo camera, complete, cost $95; Scientific American from 1859 to 1880, 4 vols. bound. D. Keesler, Stony Point, N. Y.

Sea shells of Atlantic coast, scientifically marked, for books, old or new magazines, Indian relics, natural history specimens, apparatus; anything. Wilfred Leon Miller, P. O. Box 392, Cape May, N. J.

A new 40 diameter microscope, corals, and minerals, for a stylographic pen, air gun, or offers. J. McBride, 54 Garley St., Chicago.

A dulcimer that cost $20, books and fossils, for a telescope, microscope, fossils, Indian relics, or offers. E. J. Votaw, Salem, Iowa.

A self-inking model press, 5 x 7½, cost $23; $90 worth of scroll-saw designs in lots to suit; Scientific American, 1880; Palliser's Useful Details, $3; for photo outfit or offers. C. H. Parker, Coldbrook Springs, Mass.

Telegraph key and sounder, Frank Leslie's Illustrated Magazines, mounted microscopic objects, natural curiosities, for bull's-eye condenser, photograph camera, Unabridged Webster Dictionary, or offers. W. T. Alan, Greenville, Mercer Co., Pa.

Large magic lantern, spectroscope, pantagraph, for enlarging drawings, rosewood writing desk, man's saddle, for microscope, photo outfit or offers. Thomas Walters, Bergen St., East of Brooklyn Ave., Brooklyn, N. Y.

Model card press, chase 3¼ x 5¼, with 4 fonts type, cases, etc., for good foot lathe. Mills Day, 2 Farmington Av., Hartford, Ct.

French microscope, inclines to any angle, delicate fine motion, neat upright case, cost $17.50, for scientific books; send list to W. Fitz, P.O. Box 2852, New York.

Wanted, Quinby's New Bee Keeping, for Our Own Birds of the United States, by W. S. Baily; new. Joseph Anthony, Jr., Coleta, Whiteside Co., Illinois.

Printing type, small pica; large and small capitals, and small letters; 60 to 65 lbs., including two large cases; also gothic nonpariel, for trade. J. Siler, 1242 Broadway, St. Louis, Mo.

One years' copy of Aldine, cost $5.50, and German accordion, with instructions how to use it, cost $5.00, for offers. Chas. Dempwolf, 86 Benson St., Paterson, N. J.

A Novelty printing press, with type, prints a form 5 x 7 inches, cost $40.00, for a microscope, photographic apparatus, or offers. T. W. Patterson, Warsaw, N. Y.

$80 worth of (nearly new) printing material, minerals, fossils, Aboriginal relics, etc., for scientific books, good American watch, and offers. F. M. Farrell, Cobden, Union Co., Ills.

Rocks, minerals, fossils and fresh water shells for microscope stand, $20 to $75, also for objectives, turning lathe type, and tools. D. D. Babcock, South Dansville, N. Y.

Magic lantern, in good order, condensing lens, 2½ in. diameter, 8 slides. For small photographic camera or offers. H. A. Giddings, 4 Union Place, Classon Ave., Brooklyn.

THE "ZERO" REFRIGERATOR.

One of the most valuable adjuncts to modern life is the refrigerator, preserving our food as fresh in the hottest months of summer as in the cold season. Among the various styles in the market the "Zero" has long been prominent by reason of the many excellent merits it possesses, among which may be mentioned beauty of design and excellent workmanship; the absence of all communication between the ice and provision chamber; the absence of moisture on the inside lining; the impossibility of the contact of hot air with the ice; the condensation of the moisture contained in the provision chamber on the cold surface of the ice-box, which, running off into a trough, is passed out at the bottom; the economy of ice and uniformity of temperature; and the filling of the refrigerator with cork and charcoal, which are good non-conductors, cleanly and odorless. These refrigerators are being used in many hotels, flats and private houses throughout the country, and seem to give general satisfaction. The manufacturer is A M. Lesley, of 380 Sixth Avenue, this city.

The Young Scientist

SCIENCE IS KNOWLEDGE.

KNOWLEDGE IS POWER.

A PRACTICAL JOURNAL OF

HOME ARTS.

VOL. V. NEW YORK, SEPTEMBER, 1882. No. 9.

A Story of the Sea.

ON a brown rock off the seashore a beautiful sea anemone had planted herself. She was very delicate and lovely, and when fully opened resembled not a little the gorgeous flower called the night-blooming cereus, only that instead of yellow she was tinted with shades of the tenderest apricot color, almost approaching to pink. As the movement of the water swayed her transparent petals from side to side, she looked like some strange ethereal flower, and very exquisite.

So thought a humble black king-crab, who lay in a nook amongst the rocks on the sand beneath her. He could see her every morning as he went out for his breakfast, and longed that he might go up and speak to her.

"I wonder if she would think me very impertinent if I went and talked to her? I'll try anyway." And he marched along, with his heavy armor apparently weighing him down at every other step. Soon he raised himself, and, touching one of her petal-like arms very gently, said—

"Beautiful Actinia! may a humble shell-fish venture to address you?"

"Who are you?" said she (for sea-anemones have no eyes, though they can enjoy light, like other flowers).

"Only a king-crab." he answered, very meekly, for he felt so black, and hard, and ugly compared to her, that in his humility he almost doubted if she would notice him.

"Oh, indeed!" she replied. "Well, it is a comfort to have some one at any rate to speak to; for really, what with having to shut up on account of the low tide half one's time, and, when the water does cover me and I am fit to be seen, being deprived of all society, my time and beauty are entirely wasted, and I lead the life of a stone!"

"I am truly sorry to hear how dull you

are," said the crab. "Can I do anything for you?"

"Come and tell me all the news you can!" she answered, peevishly, for she thought, "Better this ungainly fellow than no one to admire me;" but she little knew what a true unselfish nature lived under the dark shell of the king-crab.

"This tide business is a dreadful trouble," she said, discontentedly. "I wonder what occasions it. I like being in deep water, where I can always be unfolded, because I know I am really worth looking at!"

"That you certainly are!" said the crab, with honest admiration; "but I think I can explain to you what occasions it, if it would amuse you to listen."

"You may as well tell me," the anemone answered, rather wearily. With this very poor encouragement the crab proceeded, for he loved her so much that in his heart he could find no fault with her, and thought all she did perfection.

"The earth is like a ball turning round always on a stick, or axis, passed through its centre: the moon travels round the earth, and the two together make what is called a system."

"That is very stale news," laughed the anemone. "I know what you are going to say—that the moon attracts the water!"

"On the contrary," quickly responded the crab, "that is a well-known mistake amounting almost to a superstition of bygone ages, and I will show you how that idea originated. As the earth is larger and heavier than the moon, one would weigh heavier than the other. If I could put them in miniature each at opposite ends of a stick, and if I tried to balance them on my claw, we should find that, owing to the earth's greater weight, I should have to put my claw, not in the middle of the stick, but closer to the earth than to the moon. This would be the balancing point, and the centre of the system of the earth, and the moon, round which they revolve, is always in a line with each."

Here the anemone seemed a little more interested, for she unfolded every tiniest petal as if to catch every word. Encouraged by this, the king-crab continued—

"As the earth turns separately from the moon it brings its great seas and oceans every now and again opposite this centre of the system, and the moon also, they being in the same line. The waters rise and expand to this centre (but not to the moon) as they pass over them, so making a tide till they are past; and when the centre and the moon have reached the opposite side of the earth, the same sea, not having forgotten its motion, tries to rise again, and this forms a second tide. So this is why there are two tides in the twenty-four hours—a real, and what we may call a false, tide."

"Then the moon has really nothing to do with it beyond being in a line with the centre of attraction?" remarked Actinia, gracefully waving her pink arms.

"None whatever," answered the crab; "but as no one can see the centre point, and the moon can be seen, it makes people say the tides are caused by the attraction of the moon—a power that I, for one, believe she does not possess."

Just then a handsome spotted dog-fish swam past, gently touching one of the anemone's arms in recognition.

"Ah! is that you?" she said, "I thought myself quite forgotten by my old friends."

"That would be impossible, fair Actinia," said the dog-fish, with the easy grace of a refined and thoroughbred manner, for his family being a very old one were looked up to as extremely aristocratic. "My mother and sisters are spending such a pleasant time among the rocks of the great seaweed forest that stretches westward to the Bahama Islands, and are wishing so much to see you, that I came over to try and persuade you to drift over there next time the undercurrent sets in that direction."

"How very kind of you!" said the delighted anemone. "I hope it will come soon, for I am dying to get out of this dull place."

The king-crab hearing this felt a little disappointed to find that he must have succeeded so badly in amusing her, and could not help wishing also that he was

as handsome and attractive as the dog-fish, for whom the anemone showed so decided a preference, and of whose charms, after his visits, she was never tired of talking. However, he continued to do his best for her, finding it such a pleasure to minister to her in any way, for he loved her so dearly.

At last one morning, when he came to the accustomed rock to bid her "good morning," he was startled to find she was gone. Slowly and sadly he was turning away when a friend—a merry old porpoise—came swinging along past him.

"Your pretty lady-love has deserted you, I fear," he grunted out.

"Have you seen her?" eagerly asked the crab.

"Oh yes! more than two miles from here, floating away lightly with the westward current, and milord dog-fish in close attendance. I wonder you aren't jealous." And the porpoise whisked and flapped his tail about.

"Ah, no!" answered the king-crab, "jealousy is such a vulgar thing, and but another word for selfishness. If you really love anyone very much you would enjoy to know they were happy before all things; their happiness would be your first object, obtained at no matter what sacrifice to yourself. I know she is happy, and though I miss her sadly, and should dearly like to have given her the pleasure, I am very glad the dog-fish—who is a right good fellow—has taken her where she so longed to go, and I hope he and his friends will be very good to her and take great care of her."

"Ah well," said the porpoise, rolling about, "that may be all very well, but I always thought she treated you very badly, and I can't make you out!" which, of course, he couldn't, seeing that the porpoise was like the generality of the world, by whom real love with its unselfishness is rarely understood!

—Carbolic acid, diluted with ten parts of water and thrown into the cracks and crevices where ants or cockroaches abound, will invariably drive them away.

Hyacinth Culture.

DOUBTLESS many of our readers are fond of flowers, and would like to get some information regarding their management and culture. The hyacinth is a beautiful flower and a great favorite with many whose attempt to raise it has frequently ended in failure. To be successful in rearing this plant, procure a number of hyacinth glasses—say from six to twenty—fill them all with water at the same time. Fresh rain-water is to be preferred, and the glasses should be so filled that the water only just touches the base of the bulb. Rain water should not be employed unless it is quite fresh, or otherwise it soon becomes putrid, and causes the roots of the bulbs to decay. If there is no alternative but to employ hard water, let it be exposed to the action of the sun or external air for a while before being poured into the glasses.

Hard water used immediately after it is drawn from the well is apt to cause the roots to become a mass of pulp, highly offensive, and fatal in its effects. Two or three pieces of charcoal should be placed in the glasses a few days before they are occupied by the bulbs, in order to allow of the charcoal becoming saturated and sinking to the bottom, which will keep the water from turning rank, and remove the necessity of its being often changed. By taking this precaution, flowers may be raised and matured without changing the water.

Place the glasses in a dark and rather cool situation until the roots have nearly reached the bottom of the glasses, when they can be brought out to the light. A month or six weeks' confinement is quite sufficient to bring the roots to the proper state of development, so that the glasses may be removed to the light. The glasses should be placed in the most airy and lighted part of the room, and as far from the fire as possible, but where there will be no danger of frost ever reaching.

When the bulbs have been in the water a week or ten days, they should be examined, and if any decaying roots or slimy matter be found upon them, the substance should be removed at once. As the shoot or growth increases in size,

evaporation will take place; therefore, the water should be replenished at intervals, care being taken that what is supplied is not lower in temperature than that in the glass. The foliage of the plant should be kept scrupulously free from dust or dirt; a small piece of sponge being used for this purpose will do the work nicely and without injury to the plant if care be taken in the handling. When the flower spikes begin to show themselves the glasses should be kept filled with water to the brim, as at the point of flowering the bulbs absorb a great deal of moisture. The reader need hardly be reminded that when the glasses are once brought into the lighted room, the temperature of the room should be kept as even as possible.

Bulbs may be put down during the early part of November, but it is better to get them down in October when convenient. Fine plants, however, have been raised when the bulbs have been placed as late as December.

We should like very much to hear from some of our readers who have had experience in the culture of hyacinths, as we are sure the subject is one that will be interesting to most of our subscribers.

An Autumn Leaf Lamp Shade.

THE design for a lamp shade, Fig. 1, consists of a central group of either maple or oak leaves that have been thoroughly dried and pressed. The fine line border is composed of small wood ferns and parts of ferns, and smilax. The body of the frame consists of heavy but finely perforated cardboard. The dried autumn leaves and ferns are fastened to the cardboard by applying a thin coating of well cooked and thick starch to the backs of the leaves, in as small a quantity as possible, so as to avoid all spreading of the starch beyond the margins of the leaves, and the consequent disfigurement of the cardboard. After the leaves are in position, the cardboard is placed between the leaves of a book on which weights are placed to obtain extra pressure. When the leaves have become thoroughly pressed and dried, a thin coat of furniture or other varnish is applied to both sides of the board. A frame, consisting of wire of the thickness of that used on hay, is shaped as shown at Fig. 2. The ends of the wire are brought together at B, and are bound with fine wire. That part of the wire which forms a circle

Fig. 1.

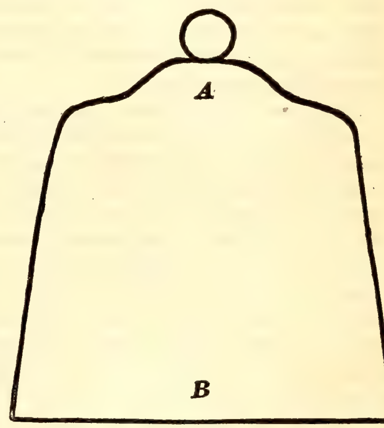


Fig. 2.

LAMP SHADE.

at A, is not bound together, but is left free, so that it can be expanded to the size of any ordinary lamp chimney. To the bottom, and half way up the sides of the wire frame, the edges of the cardboard are sewed, after which the cardboard is bound with green ribbon. The lamp-light effect of such a shade is very pleasing and soft.

How to Join a Lead Pipe.

BY AN AMATEUR.

AN amateur who can do one thing thoroughly well, and who understands the reasons for each step in the process, will easily extend his knowledge and skill to analogous cases. Now, there is scarcely a more useful handicraft in the home, especially in frosty winters, than plumbing; and the amateur who possesses even moderate knowledge of the craft will save his household a vast amount of inconvenience, and himself no small expense. The object of this paper is to describe the method of making a joint in a lead pipe running down the angle of a room, or in any similar position in which there is no side strain. Such a pipe is often split open by the frost, and it becomes necessary to cut away the damaged piece, and to replace it by a new length, involving the making of two joints, one at each end of the new piece.

In making such a joint, there are three distinct stages in the process:—

1. Shaping the ends of the pipe.
2. Putting in the solder.
3. Making the joint.

Where the amateur has most likely gone wrong has been in not attending to the distinction between 2 and 3, or perhaps in ignoring 3 altogether. The consequence is his joints leak, or even come apart without effort.

1. *Shaping the Pipe.*—The two ends to be joined should be cut off square with a small-toothed hand-saw. Then the open end of the lower pipe is to be spread out funnel-wise, by driving into it a cone of box wood made for the purpose. It is something like an elongated peg-top, and may be had for a few cents at a tool-shop. A few blows on the top of it, when placed in the open pipe, will soon produce the funnel shape. The end of the upper pipe must now be rasped all round, so as to fit easily into the funnel opening of the lower pipe. This rasping will reduce the thickness of the pipe at its opening to perhaps one-sixteenth of an inch, but care must be taken not in any way to crush up the pipe, so as to choke the waterway through it, or stoppages may occur when it is in use.

The end of the upper pipe now drops easily into the funnel of the lower one, so as to leave a narrow channel all round the top of the funnel outside the upper pipe.

2. *Putting in the Solder.*—The tools and appliances for plumbing and soldering are very few and simple. The chief agent is heat, and the chief operation applying that heat under the proper conditions for it to do its work in uniting the pieces of metal. Now, for the solder to take to the lead, it is essential that the parts of the lead pipe to be united should be perfectly bright and clean. If they are at all oxidized or dulled, as lead always becomes after exposure to the air, the solder will not take. With a pocket-knife scrape the inside of the funnel-shaped pipe-end perfectly bright; if the lead pipe is old, there will be seams of corrosion in it that must be carefully cut or scraped out, otherwise the joint may leak. Take care not to drop the chips of lead down the pipe, or they may cause trouble elsewhere. Then the outside of the rasped end must also be scraped perfectly bright, unless the rasping has done this sufficiently. The proper tool for this scraping is a "shave-hook," a triangular piece of steel at the end of a short handle, but a pocket-knife will answer every purpose. The bright surfaces soon get dull on exposure to the air, but as the joint is going to be made at once, there is no need to protect the scraped lead in waiting.

When the metal is highly heated, the action of the oxygen of the air upon it is much more rapid, and as, in making the joint, the solder itself is melted, and the lead surfaces nearly so, it becomes necessary to protect the bright surfaces with what is called a "flux," to keep the air off them when they are raised to the high

temperature required in the operation, and thus to prevent the rapid oxidation, which would frustrate the soldering. The flux usually employed for such joints as this is powdered resin, but tallow is also used.

The funnel and pipe end being scraped perfectly bright, and dropped into each other in position, sprinkle some powdered resin into the channel formed by the upper part of the funnel and the pipe that fits into it. Then put the melted solder into this channel all round. This may be done in two ways—melt the solder in a small iron ladle and pour it into the joint, or heat the copper soldering-bit, and holding a stick of solder against it, drop the solder as it melts into the joint, taking care that there is enough solder all round. The soldering-bit is a pointed piece of copper, fitted into an iron shank with a wooden handle. Some prefer the copper end at right angles to the handle, but the bit is usually made all in the same line. The bulkier the copper, within reasonable limits, the more heat it will hold.

3. *Making the Joint.*—The joint is in position, and the solder is run into it, but the joint is not yet "made." As the solder drops into the channel, it will be immediately chilled by the cold lead on both sides, and at this stage it is only like being run into a mould. There would be no amalgamation between the solder and the surfaces it is intended to unite, and it would be quite easy to pull the joint asunder while in this condition. Enough heat must be brought to bear on the joint to melt the solder, and to raise the adjoining lead surfaces to such a temperature that they shall amalgamate with the solder, and form one continuous mass of metal. The solder used with any particular metal is always such as to melt at a rather lower temperature than the metal itself, so that the solder be melted into the joint without melting the sides of the joint.

Heat the soldering-bit hot enough to melt the solder easily; then put the pointed end of it downwards into the solder that has been run into the joint, and melt it thoroughly. Carry the point of the bit in this way slowly all round the joint, thoroughly melting the solder at every point. When this has been effectually done the joint is "made." The heated bit has melted the solder, and at the same time raised the bright surfaces of lead on both sides to such a temperature that they have amalgamated with the solder, and the joint is one solid piece of continuous metal throughout. At the same time, the resin melting has kept the air from the joint and prevented oxidation.

The amateur will now let the water into his pipe, and watch with anxiety whether there is any of that exudation which tells him that his work is not perfect. If he sees those tiresome water-beads begin to stand about his joint, he had better let the water off, and when the pipe and joint are thoroughly dry, paint the joint well with any ordinary wood-paint: this will make it water-tight. But with moderate pains, and careful attention to the reasons of the thing, he will soon find himself able to make reliable joints, and will be, so far, independent of the plumber. It is an excellent plan to get a piece of lead pipe and practice making joints, cutting them open with the saw to see how the work has been done.

Marvels of Pond Life.—XIII.

In the latter part of October I observed some fragments of a new creature among some bits of Anacharis, from the Vale of Heath Pond, and searched for complete and intelligible specimens without effect. Luckily one evening a scientific neighbor to whom I had given some of the plant for the sake of the beautiful *Stephanoceri* which inhabited it, came in with a glass trough containing a little branch, to which adhered a dirty parchment-like ramifying tube, dotted here and there with brown oval masses, and having sundry open extremities, from which some polyp-shaped animals put forth long pearly tentacles margined with vibrating cilia, and making a lively current. The creatures presented an organization higher than that of polyps, for there was an evident *differentiation* and complication of parts. They belonged to the *Polyzoa* or *Bryozoa*,* a very impor-

* *Polyzoa* means "many animals," in allusion to their habit of living in association. *Bryozoa*, "moss-animals," from some forming cells having that appearance.

tant division of the *mollusca*. The *Polyzoa* are chiefly marine, and the common "sea-mat," often erroneously treated as a *sea-weed*, is a well-known form. A species of another order often picked up on our coasts is the *Sertularia*, or Sea-Fir, composed of delicate branching stems of a horny-looking substance, which, under a pocket lens, is found to contain an immense number of small cells inhabited by Polyps. It is instructive to compare the two and note how much more advanced in structure is the Polyzoon than the Polyp.

Polyzoa were formerly associated with the Polyps, to which they bear a strong superficial resemblance; but they are of a much higher degree of organization, as will be seen by comparing what has been said in a former article on the *Hydra*, with the description which we now proceed to abridge from Dr. Allman's splendid monogragh on the fresh-water kinds. In order to get a general conception of a Polyzoon, the Professor tells us to imagine an alimentary canal, consisting of œsophagus, stomach, and intestine, to be furnished at its origin with long ciliated tentacles, and to have a single nervous ganglion on one side of the œsophagus. We must then conceive the intestine bent back till its anal orifice comes near the mouth; and this curved digestive tube to be suspended in a bag containing fluid, and having two openings, one for the mouth and the other for the vent. A system of muscles enables the alimentary tube to be retracted or protruded, the former process pulling the bag in, and the latter letting it out. The mouth of the bag is, so to speak, tied round the creature's neck just below the tentacles, which are the only portions of it that are left free. The investing sack has in nearly every case the power of secreting an external sheath, more or less solid, and which branches, forming numerous cells, in which the members of the family live in a socialistic community, having, as it were, two lives, one individual, and the other shared in common with the rest.

The whole group of tubes and cells, whatever may be the form in which they are aggregated, is called the *Polypary*, or, as Dr. Allman prefers, the *Cœnœcium* (common house); the creature he names a *Polypide** (polyp-like); and the disk which bears the tentacles (*Lophophore* (crest-bearer). There are some more hard words to be learnt before the student can enjoy himself scientifically among the Polyzoa, and we shall be compelled to employ some of them before we have done; but we will now endeavor to describe what was presented to our view by the specimen obtained from the Hampstead Pond, which was a branch of *Plumatella repens*.

When all was quiet, the mouths of the bags belonging to each cell were slowly everted, and out came a numerous bundle of tentacles, which were either spread like the corolla of a flower, or permitted to hang dishevelled like the snake-locks of Medusa. We will suppose these organs symmetrically expanded, and that we are looking down upon them with a magnifying power of sixty diameters, the light having been carefully adjusted by turning the reflecting mirror a little on one side, to avoid a direct glare. The tentacles, each of which curves with a living grace, and displays an opaline tint in its glassy structure, do not form a complete circle, for at one place we discern two slightly diverging arms of the disk, or frame (Lophophore) from which they grow.

These arms support tentacles on each side, and leave a gap between, so that the whole pattern is *crescentic*, or crescent-shaped, and not circular. Extending as far as the points of the arms, and carried all round the crescent, is an extremely delicate membrane, like the finest gauze, which unites all the tentacles by their basal portions, and makes an elegant retreating curve between every two. Each tentacle exhibits two rows of cilia, which scintillate as their vibrations cause them to catch the light. The motion of the cilia is invariably *down* one side and *up* the other, the current or pattern being carried on from one tentacle to the other, all through the series. This characteristic, and the facility with which each cilium can be distinguished, gives great interest and beauty to the spectacle of this wonderful apparatus, by which water-currents are made to bathe the tentacles and assist respiration, and also to carry food towards the mouth, over which a sort of finger or tongue is stretched to guard the way, and exercise some choice as to what particles shall be permitted to pass on. This organ is called the *epistome*, from two Greek words, signifying "upon the mouth."

If the cell is an old one, it may be covered with so much extraneous matter as to obscure the economy within; but we are fortunate in having a transparent specimen before us, through which we can see all that goes on. The alimentary tube, after forming a capacious cavity, much longer than it is broad, turns round and terminates in an orifice near the mouth, and just below the integuments. When refuse has to be discharged, this orifice is protruded; and after the operation is over, it draws back as before. Long muscles, composed of separate threads or

---

* *Polyzoon* is preferable, as avoiding confusion with *polypite*, used for another class of objects.

fibres, pull the creature in and out of its cell, and at the part where the stomach ends, and the intestine turns round, is attached a long flexible rope, called the *funiculus*, which goes to the bottom of the cell. The passage of the food down to the stomach, its digestion, and the eviction of the residue, can all be watched; and when a large morsel is swallowed, the spectacle is curious in the extreme.

One day a polyzoon caught a large rotifer, (*R. vulgaris*,) which, with several others of its tribe, had been walking over the *cœnœcium*, and swimming amongst the tentacles, as if unconscious of danger. All of a sudden it went down the whirlpool leading to the mouth, was rolled up by a process that could not be traced, and without an instant's loss of time, was seen shooting down in rapid descent to the gulf below, where it looked a potato-shaped mass, utterly destitute of its characteristic living form. Having been made into a bolus, the unhappy rotifer, who never gave the faintest sign of vitality, was tossed up and down from the top to the bottom of the stomach, just as a billiard-ball might be thrown from the top to the bottom of a stocking. This process went on for hours, the ball gradually diminishing in size, until at last it was lost in the general brown mass with which the stomach was filled. The bottom of the stomach seems well supplied with muscular fibres, to cause the constrictions by which this work is chiefly performed, and by keeping a colony for a month or two, I had many opportunities of seeing my Polyzoa at their meals.

When alarmed the tentacles were quickly retracted, but although these creatures are said to dislike the light, and usually keep away from it in their native haunts, my specimens had no objection to come out in a strong illumination, and seemed perfectly at their ease. They were indeed most amiable creatures, and never failed to display their charms to admiring visitors, who rewarded them with unmeasured praise. Twice I had an opportunity of observing an action I cannot explain, except by supposing either that the tentacles of *Plumatella* have some poisonous action, or that rotifers are susceptible of fear. On these occasions the common rotifer was the subject of the experiment. First one and then another got among the tentacles, and on escaping seemed very poorly. One fellow was, to borrow a phrase from Professor Thomas Sayers, "completely doubled up," and two or three seconds—long periods in a rotifer's life—elapsed before he came to himself again.

By keeping a colony of the Plumatella for a wew weeks in a glass trough, and occasionally supplying them with fresh water from an aquarium, containing the animalcules, they are easily preserved in good health, and as they develop fresh cells, the process of growth may be readily watched. This production of fresh individuals enlarges the parent colony, but could not be the means of founding a new one, which is accomplished by two other modes. A little way down the cells Professor Allman discovered an ovary attached to the internal tube by a short *peduncle*, or foot stalk, while a testis or male generative organ is attached to the *funiculus*, or "little rope," we have already described.

July and August are the best times for observing the ovaries, and they are most conspicuous in the genera *Alcyonella* and *Paludicella*. True eggs are developed in the ovaries in a manner resembling this mode of multiplication in other animals; but there is another kind of egg, or, perhaps to speak more properly, a variety of bud, which is extremely curious. In looking at our specimens we noticed brown oval bodies in the cells. The centre is dark covered with a net-work, which is more conspicuous in the lighter colored and more transparent margins. These curious bodies are produced from the funiculus, and act as reserves of propagative force, as they are not hatched or developed until they get out and find themselves exposed to appropriate circumstances. Professor Allman names them *Statoblasts*, or stationary germs, and they bear some resemblance to what are called the "winter eggs" of some other creatures. The Professor was never able to discover any mode by which they were permitted to escape from the cells, and in our colonies none were allowed to leave their homes until the death of their parent, and the decomposition of its cell had taken place; a process which went on contemporaneously with the growth of new cells, until the plant on which the *cœnœcium* was situated, rotted away, and then unfortunately the whole concern went to pieces.

The tubes of the *Plumatella*, and of most other Polyzoa, are composed of two coats, called respectively *endocyst* and *ectocyst*, that is, "inner case" and "outer case." The first is vitally endowed, and exhibits vessels and muscular fibres. The second or outer case is thrown off by the first. It is a parchment-like substance, strengthened by the adhesion of dirt particles, and does not appear to exercise any vital functions, but to be merely a covering for protection. The inner layer terminates in the neck of the bag before described, as exserted when the polypide comes out, and inverted when it goes in. This mode of making a case or sheath by inversion of a bag is technically called *invagination*, and is readily seen in new and transparent cells.

The movement of *eversion*, or coming

out, is chiefly produced by the contraction of the endocyst; while the *inversion*, or getting in again, is performed by the long muscles, which, when the animal is extended, are seen attached to it like ropes. Upon these muscles Professor Allman remarks that they are "especially interesting in a physiological point of view, as they seem to present us with an example of true muscular tissue, reduced to its simplest and essential form. A muscle may here be viewed as a beautiful dissection far surpassing the most refined preparation of the dissecting needle, for it is composed of a bundle of elementary fibres, totally separate from one another through their entire course." He further adds, "The fibres of the great retractor muscle are distinctly marked by transverse striæ—a condition, however, which is not at all times equally perceptible, and some of our best observers have denied to the Polyzoon the existence of striated fibre."

We can confirm the fact of this sort of fibre being present, but we fancy a reader not versed in the mysteries of physiology exclaiming, 'What does it matter whether his fibres are striped or not?'

Physiologists used to suppose there was a strong and marked distinction and separation between *striped* muscles, that is, muscles the fibres of which exhibit transverse stripes when magnified, and those which do not. Kolliker, however, says this decided separation can no longer be maintained,* and he gives instances in proof of the connections that can be traced between the two forms. In the higher animals the striped muscles are the special instruments of *will*, and of movements that follow, or are accompanied by, distinct sensations. Striped fibre must be regarded as the highest form; and as a muscle of this sort contracts in length it increases uniformly in breadth.

There are many other genera and species of fresh-water polyzoa besides the *Plumatella repens*, and they are found attached to sticks, stones, or leaves, generally to the under surface of the latter. They are all objects of great interest and beauty, which, whatever their diversity, conform sufficiently to one type that the student who has observed one, will easily recognize the zoological position of another. They should be viewed by transmitted and br dark-ground illumination, which produces very beautiful effects. To observe them in the performance of their functions, they require more room than the live-box can afford, but are well shown in the glass trough, whose movable diaphragm enables them to be brought near enough to the object-glass, for the use of a power of about sixty linear for general purposes, and of from one to two hundred for the examination of particular parts. For a more detailed examination dissection must be employed, but all that we have mentioned can be seen without injury to the living animal, if specimens are kept till new cells are formed in water, which does not contain enough dirt to render their integuments opaque.

* 'Manual of Human Microscopic Anatomy, p. 63.

Scientific Absurdities.

WHEN scientific writers depend upon their imagination for their facts, they are apt to make rather wild work. There are very few men who can follow closely, step by step, the scientific *necessities* of any supposed combination, and hence when a supposed scientific discovery is described without having been actually put to the test, the writer is very apt to overlook some essential point. A writer in *Les Mondes*, under the heading, "Hunting by Electricity," thus describes an experiment, which, as any tyro ought to know, will not work: "A new application of the Ruhmkorff coil has been made in the neighborhood of Marseilles. Instead of using bird-lime on trees which are frequented by birds of passage, a copper wire is wound around the trunk and a decoy attached to a neighboring staff. When a numerous flock has been attracted by the decoy, a shock is sent by the commutator, and they are more surely stunned than by a rifle."

That the bird may be killed, or even stunned, it is necessary that the shock be passed through it, and to do this it must be placed between the poles. A good conductor connecting these poles, may be safely held in the hand, no matter how powerful the discharge may be. We should be very much surprised to learn that the birds in the neighboring wood of Marseilles are in the habit of deliberately sitting down between the poles of a Ruhmkorff coil, so as to be killed, even though there is a handsome decoy attached to a neighboring staff.

The same writer also tells us that "experiments of a similar kind have also been made by M. Dalmas upon the vines at his country-seat, and powerful shocks are said to have destroyed the parasites to-

gether with their eggs. If this statement is confirmed, the ingenious inventor may reasonably expect the prize of 100,000 francs, which has been offered for the destruction of the phylloxera."

It strikes us that this is a good deal like the Dutchman's powder for killing fleas, the method of using which was, first to catch the flea and then put the powder in its mouth.

Planting for Timber and Fuel.

The attention of our people in the older States is being properly turned to planting rocky ridges and worn-out pastures with forest trees. This work is done by those having no expectation of cutting timber themselves, but with a view to improve their property for future sale or for their heirs. These old pastures are now worth $10 or less per acre. Forty or fifty years hence, covered with heavy timber, they would be worth $300 or more per acre. Two elements may safely enter into this calculation of the profit of tree planting: the steady growth of the trees, and the constant increase in the price of fuel and timber. There is great difference in the price of the varieties of wood, but still more in the rapidity of their growth. Hickory grows more rapidly than white-oak, and in most markets is worth a quarter more for fuel. Chestnut grows about three times as fast as white-oak, and for many purposes makes quite as good timber. It is in great demand by the ship-builders and cabinet-makers. The chestnut, the tulip tree, and the hickory attain a good size for timber in twenty or twenty-five years, and the spruce and pine want about fifty years. The maples grow quite rapidly, and are highly prized, both for fuel and for cabinet purposes. On light sandy soil, the white pine will grow rapidly, and cannot fail to be a good investment for the next generation. As a rule, the more rapid growing trees, if the wood is valuable, will pay better than the oaks.

Glycerine as an Anti-Freezing Agent.

The growing use of hydraulic machinery for riveting, flanging, etc., in our iron works, and for elevators, hoisting machinery, cranes, etc., makes the question of avoiding the danger incident to the freezing of water in the pipes an important one. The *Engineer* states that in England there is no generally adopted method. An admixture of alcohol, salt or glycerine has been tried, and Mr. Tweddell, well known in connection with hydraulic machinery, made some experiments on the effect of the addition of glycerine. In open vessels, at a temperature of 28°, when pure water froze rapidly, only a lump of rotten ice was formed when 1 per cent. of glycerine was present, less still with 2 per cent., the ice formed not being sufficiently solid to flow, especially with a pressure of 1,500 lbs. per square inch. One firm found that in adding one gallon of glycerine to 300 gallons of water no trouble whatever was experienced, while another firm uses 25 per cent., although they believe 10 per cent. to be enough for ordinary purposes. Salt is much cheaper, but while glycerine rather preserves leather packings than otherwise, common salt destroys them, especially when in cast iron. Glycerine has also been used with good effect in gas-meters.

Deterioration in Thermometers and Hydrometers.

M. Saleran, in *Comptes Rendus*, calls attention to defects liable to be produced in thermometers and hydrometers if used for certain purposes. Changes in thermometers ranging as high as 8° to 10° C. occur at printing-ink works, where oils are heated for several days to 670°, in glycerine works, and with rectifiers of benzol. Glass is not only modified when heated to 300°, but it undergoes true deformation at far lower temperatures. Thus, the hydrometers used in sugar works, which are often exposed for a considerable time to temperatures of 95° are affected. After an immersion of some days they are completely modified, their weight decreases and they become erroneous to the extent of 7° to 8° B. The London *Chemical News* adds that in many chemical works it has been found necessary to submit all hydrometers used for hot liquids to a weekly comparison with a standard instrument.

Hardening and Testing.

To *really test* the hardness of the surface of metal, we must take a *new*, or at least a good, *dead smooth* file and apply one corner of it to a corner rather than on a flat surface of the metal to be tested, pressing the file very firmly against the work. A coarse file, even if a new one, is useless to test with. The greatest degree of hardness is obtained by plunging the red-hot steel into mercury. Steel hardened from the surface inward is hardest on the surface, while in steel that has been tempered the exterior is the softest. In the one case because the surface was cooled in advance, in the other because it was heated in advance. Files are hardened in the following mixture: 2 parts (by weight) of

salt, 15 parts of rye meal, and 30 parts of burnt cow hoofs, all ground together and mixed with a sufficient quantity of water to make a pasty mass, with which the files are covered. When dry, they are placed in a fire. If, during the heating, the coating should drop off at certain places, the files are promptly withdrawn and the place exposed is covered with dry hoof powder. It is returned to the fire, where it is left until a temperature is reached which best suits the steel of which it is made. Then the file is plunged vertically into the bath, care being taken not to move them to the right or left, as that would cause warping. The bath is made in the following manner: 28 parts of salt are dissolved in about 5 parts of water, to which a handful of iron scale is added. The tangs are softened by being plunged into red-hot lead.

A Puzzle for Young Latin Pupils.

A few years ago Dr. H. D. Paine, of this city, sent the following card to the members of the New York Medical Club:

"SCIENS, SOCIALITE, SOBRIETE."

Doctores—Ducum nex mundi nitu Panes; tritucum at ait. Expecto meta fumen tu te & eta beta pi. Super atento, uno. Dux, hamor clam pati, sum parates, homine, ices, jam, etc. Sideror hoc. Anser.

"FESTO RESONAN FLOAS SOLE."

Our young readers will find some amusement in the endeavor to translate the above.

Practical Hints.

Wild Cherry Wood.—The wild cherry, *Cerasus serotina*, is said by Robert Douglas, of Illinois, to be one of the most rapid growers of all our valuable Northern hard-wood forest trees, making lumber almost equal in value to the black walnut. It grows freely on any dry land, even if too poor for agricultural purposes. It is healthy everywhere, of upright growth, and is very easily transplanted.

To Kill Knots before painting, make a mixture of glue size and red lead; or shellac dissolved in alcohol and mixed with red lead; or gutta percha dissolved in ether, will. either of them, make a good coating for knots, but will not stand the sunshine, which will draw the pitch through the paint. The best method is to cover the knot with oil size and lay a leaf of silver over it.

Sharks.—The skins of certain sharks are used in jewelry for sleeve buttons and the like, and when dried and cured take a polish almost equal to that of stone, and greatly resemble the fossil coral *porites*. The vertebræ of the shark are always in demand for canes. The opening filled with marrow during life is now fitted with a steel or iron rod. The side openings are filled with mother-of-pearl, and when polished the cane is very ornamental.

Removing Stains of Nitrate of Silver.—Cyanide of potassium is the substance generally used, but its employment is fraught with danger, as it may be absorbed through abrasions of the skin. A much safer way, and equally expeditious, is to soak the stains, whether on the hands or on dresses, with a strong fresh solution of iodine, and after a few minutes to treat them with a concentrated solution of sodium hyposulphite. The iodine converts the silver into iodide, which is afterwards dissolved off by the hyposulphite.

Poisonous Wall-Papers.—The full extent of the peril attending the use of arsenical wall-papers is not yet, it would seem, realized. It is startling to find that surprise has been excited by the statement that not only green but other brightly-colored papers contain arsenic. As a matter of fact, we believe that mineral substances form an integral part of many coloring matters extensively employed, and, while needless or at least avoidable, their presence is to be suspected in most papers which have not been prepared with a special view to health; hence the need of unusual precautions.—*London Lancet.*

A Large Monolith.—At a granite quarry in Westerly, Rhode Island, there was recently detached a monolith 150 feet long, 10 feet wide, and 8 feet thick, weighing over 1,000 tons. These dimensions greatly exceed those of the Obelisk of Semiramis, the largest of the Egyptian monoliths. The stone was loosened by one oblong blast-hole in such a simple and perfect manner that the theories and conjectures advanced by many as to the methods of the Egyptians appear absurd. It contains over 12,000 cubic feet of granite which, cut into smaller blocks, will fetch about $30,000. Mr. French, the engineer in charge, is quite positive that it could be taken to New York City, finished as an obelisk, and erected for about $150,000.

How to Keep Bouquets—There are various receipts for keeping bouquets fresh. Some people stick them in moist sand; some salt the water in the vases, and others warm it; others, again, use a few drops of ammonia. My rule is, to cool the flowers thoroughly at night. When the long day of furnace heat has made the roses droop aad their stems limp and lifeless, I clip them a little, and set them to float in a marble basin full of very cold water. In the morning they come out made over into crisp beauty, as fresh and blooming as if just gathered. All flowers, however, will not stand this water-cure. Heliotrope blackens and falls to pieces under it; azaleas drop from their stems; and mignonette soaks away its fragrance. For these I use dry cold air. I wrap them in cotton wool, and set them on a shelf in the ice-chest. I can almost hear you laugh, but really I am not joking. Flowers thus treated keep perfectly for a week with me, and often longer.—*St. Nicholas.*

EXCHANGES.

Only those who are *yearly* subscribers, and whose names are entered on our books have the privilege of inserting exchanges.

Exchanges must be on separate slips of paper or postal cards. If mixed with business matter in letters or cards they are filed away and never reach the printer.

Exchanges must not exceed thirty words.

Buying and selling belong to the advertising department.

We reserve the right to omit the exchange column, when we have not room for it, and the amount of space at our disposal will regulate the number of insertions given to each *exchange*, the preference being always given to those who have not previously used our columns.

Wanted engraver's tools with book of instructions, for a Victor Press, with cabinet, 2 type cases, type, ink roller and furniture complete; perfectly new. L. Warren, 72 Cumberland St., Brooklyn, N. Y.

A Fletcher Foot-Blower, cost $5, as good as new; will exchange for a Cushman, 2 in. or up scroll chuck, or other make; will give a satisfactory trade on the difference in price, if any. Louis Lutz, St. Clair Street, Toledo, O.

I have a lot of "Galaxy" (magazines) which I would like to exchange for an air rifle in good condition, a collection of birds' eggs, or offers. W. B. Greenleaf, 480 La Salle Ave., Chicago, Ill.

I have a Mechanical Telegraph with book of instructions, books, etc., which I wish to exchange for good microscopical objects, mounted on 3 x 1 slips. Address, with list, J. H. Frey, Millersburg, Ohio.

To exchange, "How to Use Microscope," Wells' "Natural Philosophy," and many other books, chemical apparatus, etc., for good photographic camera, and lenses. W. H. Weed, 254 Putnam Ave., Brooklyn, N. Y.

Wanted "Quimby's New Bee Keeping," for "Our Own Birds of the United States," by W. S. Baily; new. Joseph Anthony, Jr., Colota, Whiteside Co., Ill.

Wanted a good book in anatomy, in exchange for a book on chemistry, or for story books. A. G. G., Box 26, Summit, New Jersey.

A German-silver trimmed, patent lined, cocoa flute, cost $4, in good order, for good spy-glass, photo-material, or offers. Ewing McLean, Greencastle, Ind.

I have some fossil shells from the west bank of the Mississippi, to exchange for Indian relics. A. W. S., 187 E. 71st St., N. Y.

I have a magic lantern, Ruby pattern, nearly new, and 5 views; also "Our First Century," bound in leather, cost $7; state what is wanted in exchange. I. N. Spencer, Box. 217, So. Manchester, Conn.

First-class telegraph instrument and attachments, and "Wood's Botany," for bound volumes of periodicals, books, or offers. H. P. Albert, Anderson, Iowa.

Wanted a book on treatment and care of canary, also breeding of same; will give in exchange book named "Market Garden, Flower Garden and Bees," or 40 "Scientific Americans" or "Seaside Libraries;" want also old books. M. J. Mulvihill, Norwalk, Conn.

Coins, minerals, stamps, books, type, fishing tackle (very complete) and fish pole, bronze inkstand, etc., for coins, medals, stamps, war envelopes, old newspapers, and Continental, Colonial and Confederate currency. F. F. Fletcher, 103 Main St., St. Johnsburg, Vt.

Blow-pipe set (cost $10), large illustrated family Bible (cost $7.50), for Wood's Botany, Dana's Geology, or printing press and type. H. W. Noble, Box 134, South Dansville, N. Y.

Wanted, offers for fossil shells from the west coast of Africa. A. W. Seward, 187 E. 71st St.

I have a number of birds' eggs I should like to trade for other birds' eggs; send for list of trading eggs. A. G. G., Box 26, Summit, New Jersey.

For a microscope stand or offers, a 36-inch turning lathe (new) and a number of scientific books; send for list. A. Kendall, Somerville, Mass.

Wanted services of amateur printer with small office (or large), in exchange for an interest in a well-established weekly paper, good size. Eagle Office, Plymouth, N. H.

American Agriculturist microscope, new, cost $15, for amateur photographic apparatus, lever watch, 22 calibre breech-loading sporting rifle or magic lantern of equal value. Wm. A. Walker, Rockland, R. I.

I. T. Bell, Franklin, Pa., has back numbers of Scientific American, Forest and Stream, and Young Scientist, good flute, chessmen, books, etc., for good magic lantern, revolver, scarce coins, or offers.

A steel spring bracket-saw, 2 doz. saw blades, and about 1 doz. patterns for a good stylographic pen or offers; send postal before exchanging. Geo. Oakley, Rutherford, N. J.

A rosewood banjo, 11 inch head, 12 nuts, fully strung, together with lot of dime banjo music and instructions, for microscope, Webster's Unabridged, monkey, squirrel and cage, or offers. J. DeWitt Clark, P. O. Box 37, Brooklyn, N. Y.

For self-inking printing press and type, one Henry rifle, 16 shot, 44 cal., cost $40, in good order, or one double barrel shot gun, barrels London fine twist, or offers. J. B. Garrison, Belton, Bell Co., Texas.

What offers for "The Chefs D'Oeuvre D'Art, Paris Exhibition 1878," cost $16, good as new, bound; 1 large photo camera, complete, cost $95; Scientific American from 1859 to 1880, 4 vols. bound. D. Keesler, Stony Point, N. Y.

Sea shells of Atlantic coast, scientifically marked, for books, old or new magazines, Indian relics, natural history specimens, apparatus; anything. Wilfred Leon Miller, P. O. Box 392, Cape May, N. J.

A new 40 diameter microscope, corals, and minerals, for a stylographic pen, air gun, or offers. J. McBride, 54 Garley St., Chicago.

A dulcimer that cost $20, books and fossils, for a telescope, microscope, fossils, Indian relics, or offers. E. J. Votaw, Salem, Iowa.

A self-inking model press, 5 x 7½, cost $23; $90 worth of scroll-saw designs in lots to suit; Scientific American, 1880; Palliser's Useful Details, $3; for photo outfit or offers. C. H. Parker, Coldbrook Springs, Mass.

Telegraph key and sounder, Frank Leslie's Illustrated Magazines, mounted microscopic objects, natural curiosities, for bull's-eye condenser, photograph camera, Unabridged Webster Dictionary, or offers. W. T. Alan, Greenville, Mercer Co., Pa.

Large magic lantern, spectroscope, pantagraph, for enlarging drawings, rosewood writing desk, man's saddle, for microscope, photo outfit or offers. Thomas Walters, Bergen St., East of Brooklyn Ave., Brooklyn, N. Y.

Model card press, chase 3¼ x 5¼, with 4 fonts type, cases, etc., for good foot lathe. Mills Day, 2 Farmington Av., Hartford, Ct.

French microscope, inclines to any angle, delicate fine motion, neat upright case, cost $17.50, for scientific books; send list to W. Fitz, P.O. Box 2852, New York.

Wanted, Quinby's New Bee Keeping, for Our Own Birds of the United States, by W. S. Baily; new. Joseph Anthony, Jr., Coleta, Whiteside Co., Illinois.

Printing type, small pica; large and small capitals, and small letters; 60 to 65 lbs., including two large cases; also gothic nonpareil, for trade. J. Siler, 1242 Broadway, St. Louis, Mo.

One years' copy of Aldine, cost $5.50, and German accordion, with instructions how to use it, cost $5.00, for offers. Chas. Dempwolf, 86 Benson St., Paterson, N. J.

A Novelty printing press, with type, prints a form 5 x 7 inches, cost $40.00, for a microscope, photographic apparatus, or offers. T. W. Patterson, Warsaw, N. Y.

$80 worth of (nearly new) printing material, minerals, fossils, Aboriginal relics, etc., for scientific books, good American watch, and offers. F. M. Farrell, Cobden, Union Co., Ills.

Rocks, minerals, fossils and fresh water shells for microscope stand, $20 to $75, also for objectives, turning lathe type, and tools. D. D. Babcock, South Dansville, N. Y.

Magic lantern, in good order, condensing lens, 2½ in. diameter, 8 slides. For small photographic camera or offers. H. A. Giddings, 4 Union Place, Classon Ave., Brooklyn.

The Young Scientist

SCIENCE IS KNOWLEDGE.

KNOWLEDGE IS POWER.

A PRACTICAL JOURNAL OF

HOME ARTS.

VOL. V. NEW YORK, OCTOBER, 1882. No. 10.

Give the Boys Tools.

GIVE the boys tools and let them cut, chip and whittle to their heart's content. He will be a poor kind of a boy that will not use a knowledge of tools with advantage to himself and friends. The following extract from a lecture by James Parton, the biographer, contains a great deal of sound sense on the subject, the remarks are intended more particularly for college students, but in a measure they are applicable to the condition of all boys. A knowledge of tools and their uses, will necessarily lead the young mind to inquire into the nature of the materials on which the tools are to be employed, and this again leads to other inquiries, and thus, step by step, boys may be led on to the acquisition of the most useful and practical kind of knowledge. Indeed, parents should make it a point to see too it that their boys have tools and appliances of a kind they desire, and they should be encouraged in their use and permitted to do whatever odd jobs may be needed about their homes. The advantages of being able to perform a good piece of work are incalculable to a young man, and must be quite obvious to every sensible and thoughtful parent.

Mr. Parton says: "The attempt, I trust, is about to be abandoned to educate human beings through the brain alone. The hand, the wonderful human hand, will perhaps soon resume its part in education. It is only by discipline and by labor that the world can be conquered. The military cadet has an exceptional advantage in being able to learn his trade and get his knowledge at the same time. Three years ago I visited Cornell, and was told that nothing was more successful than the machine-shops. At Eton, one of the most aristocratic of the English public schools, the students, the year before last, made a five horse-power steam-engine which is used in their shops for turning their lathes. All the elder boys have

their separate forges. The education which leaves the hand undextrous and the arm puny is not culture, but degeneracy. Let us not forget that the men who have made America have all been educated by head and by hand, and the men who have misled America have been educated otherwise. Washington used four trades, three of which he knew thoroughly. Jefferson knew three or four trades. Franklin, besides being an excellent printer, was a jack-of-all-trades, and, contrary to the proverb, very good at several of them. Look through the history of one hundred men who have become illustrious, and you will find that the majority of them had their heads knocked against something hard in their early days. Dickens working in the blacking-shop is an example. I have in my mind's eye a glorious university, completely organized and equipped to afford an education such as the future man will be given. It looks not at all like Oxford or Cambridge, or even like Harvard. It looks more like a factory village situated in the midst of a finely cultivated farm of 1,000 acres, with beautiful gardens and parks, the whole the centre of a thriving industry such as our factory villages might be, must be, shall and are just going to be, for man will not long be the submissive vassal that he is now. This university of mine shall have a chime of bells, which, at six A.M. summons 2,000 men to rise and cast off sloth, and put on working men's clothes and prepare for labor. At seven they are in their different shops, workers in wood, in metals, in leather, in stone, in hemp, in cotton, in flax, in wool. For three hours they labor, being held to a strict account for the use or abuse of tools, material, and time. In summer a portion of each day is spent by all upon the land, so that all may have insight, some practical knowledge, of farming, of horses, of cattle, of the dairy, the garden, the orchard. At ten, all this is over, except in harvest-time or other periods of pressure. The chimes now send these workmen to their rooms, where they remove the dress and the garments of manual labor, and come out to class, and remain all day university students."

While we do not quite agree with all that the speaker puts forth in the foregoing extract, we are satisfied he has struck the right chord, and we hope that not only all our colleges will have workshops attached to them, but that our common and grammar schools will have workshops and laboratories connected with each and every one of them. After all, it is not great military heroes that make a nation mighty, it is the combined efforts of physical science and industry that build a lasting empire.

That nation is greatest that possesses the greatest number of intelligent workers.

Christmas Gifts.

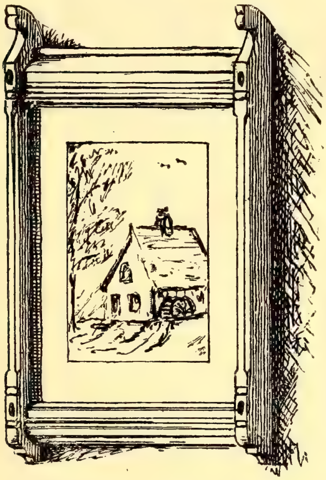
BY "OUR NED."

THE time-honored custom of making Christmas gifts to those we love is one we all revere. Doubtless many of our older readers can look back to the days of their youth, and with pleasurable feelings recall to mind many little gifts that were made and received, gifts that were made by hands that are now stilled in death, and which have acquired a value on this account, that gold or silver cannot equal; but how much more do we prize a gift if we know it to be the work of the hands that gave it? Indeed a gift, the product of the hands that makes it, possesses a two-fold value—the actual value of the gift, and any value we may attach to it as being the work of the hands of the giver—and this leads us to suggest that many of our readers might make, between now and the coming holidays, some little piece of workmanship that would be useful, lasting, and pretty, for gifts to their friends, and which, we are sure, would be appreciated much more by the recipients than if the presents were some of the dainty glittering articles that are now offered for sale at most of the fancy stores.

To aid the young worker in this object the following suggestions are offered with a view of helping him to decide what articles to make, and to assist him in making them. It is also proposed to

give the girl a chance to either help their brothers or near friends to make the articles, or to decorate them after they are made, or to make something of their own accord.

Now, let us suppose Robert has an uncle he wants to give something to; he looks about in his uncle's room and spies a place on the wall where a picture ought to hang to break the dead surface. It immediately occurs to Robert that one of the best things he can do is to make a nice picture frame for the vacant spot and give it to Uncle Joe for a Christmas gift. Robert has some knowledge of tools, and has a fair supply of them, besides having a foot-lathe and a well-built scroll-saw. He goes to work and makes a frame like the one shown in the cut.



The frame is made to receive glass 12 x 16 inches, and has the sides made of cherry, oak or other wood, one inch thick and one inch and three-quarters wide. The ends of the side are made a little ornamental by being shaped with the scroll-saw. The front edges are chamfered, or bevelled off as may be seen by examining the cut. The top piece is about an inch and a quarter thick and two inches wide, and is worked to the shape shown; it falls back from the front about half an inch, but is flush on the back and rebated to received the glass. The bottom piece is about one and a quarter inches thick, and one and a half inches wide, and is worked to shape by planes or chisels. The whole is made of cherry, oak or other suitable wood that may be handy. The top and bottom pieces may be fastened into the sides by tenon and mortise, or may be doweled and well glued in. Other modes of fastening will suggest themselves, but Robert adhered to the good old honest tenon and mortise, as he thought it the strongest and most durable. When the frame was completed and nicely sand-papered until it was smooth and clean, Robert thought he would like to ebonize it, that is, make it appear like ebony. To do this he turned over to page 156 of his *Workshop Companion*, and found that he had to apply a boiling decoction of logwood to the work three or four times, allowing it to dry before the next washing took place. When the fourth coat was perfectly dry the whole was washed with a solution of acetate of iron, which he made by dissolving iron filings in vinegar. This made an excellent stain as it penetrated to some considerable distance into the wood.

At this juncture the frame looked like a solid piece of ebony unpolished and rather rough. He smoothed it down again with very fine sandpaper, and rubbed it with a linen cloth. The dead black, however, did not look so nice as he thought it would, so he bought a bottle of liquid gold at the nearest store where artists' supplies were kept. With this gold he touched up the cross indentations on the sides of the frame, and "cut in" some very fine lines on the top and bottom pieces. This process relieved the work wonderfully and gave the frame a real artistic appearance. He then gave the whole work two or three coats of thin shellac varnish, and rubbed the whole down with finely powdered pumice stone applied with a clean cloth and water.

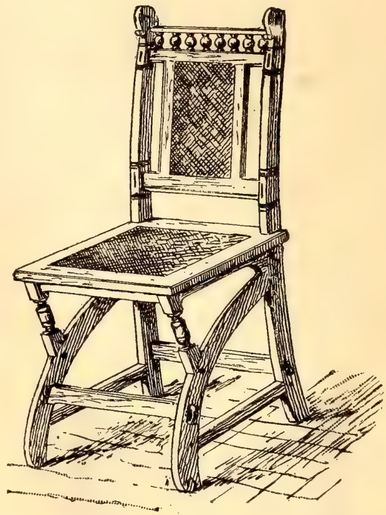
The frame being finished, Amy, Robert's sister, undertook to furnish a picture to fill the frame. She had some knowledge of drawing, not much to be sure, but just enough to be able to illustrate a flower, a spray, or a simple landscape, and her

knowledge of coloring, though limited, was always guided by good taste. Of course she used her best efforts to make Uncle Joe a picture, and the result was a very decent sketch of an old mill done in monochrome or single color.

Amy also made another picture for the frame that looked very well, but after consideration, she decided to give Uncle Joe the sketch of the mill. The other picture was formed by taking one of the statue pictures, that are so abundant in many of our pictorial papers, and cutting the paper carefully away from the picture all round, leaving only the pedestal or stand along with the statue. When this is satisfactorily done the print is carefully pasted on a back-ground of black velvet, when a beautiful picture is obtained, which when framed with an oval arched headed, grey pebbled mat, is very pleasing, and more particularly so when a spray of leaves or flowers is painted in appropriate colors on one side of the mat, as Amy treated her picture.

Robert was very well pleased with the result of his labors and determined to continue them, but in another direction. Robert had an aunt as well as an uncle. Robert was fond of his aunt, and it was a matter of pleasure as well as of duty to make her something, but the question was "what will I make her?" He finally decided to make her a chair, and the style of chair chosen is shown in the engraving. He chose this style of chair because it is easily made and would give him an opportunity to use both his scroll saw and lathe.

The chair is made of white ash, and is put together very strongly with mortises and tenons. The frame-work in the back is formed of stuff one inch by one and a half inch, with the exception of the bottom piece, which is two inches wide. The little rail on the top of the turned spindles, is one inch by three-quarters of an inch laid flatways on the turned work. The spindles are two inches long from shoulder to shoulder, and are turned to shape in the lathe. A pin three-eighths in diameter and about a half an inch long is left on each end of the spindles. These pins go into holes made in the two top cross rails as shown. Care is required in boring the holes in the upper rail so that they may not go through and show on the top of the work.



The back uprights show one and a quarter inches in thickness and two inches in width, and are two feet ten inches high from the floor. A cross rail, not seen in the engraving, is framed in between the uprights. Another rail is framed in lower down, as shown. The segmental or curved pieces forming the front legs, are the same thickness and width as the back legs. The turned uprights are one and a quarter inches square, and have on their top ends pins to hold the seat, and on their lower ends tenons to fit snugly into mortises made in the curved pieces.

The lower rails are made of stuff one by one and a half inches and are tenoned to fit in mortises made in the several legs. The frame for the seat is made from stuff one by one and three-quarter inches, and is framed together with mortise and tenon.

Previous to commencing work Robert made a full sized rough pencil drawing of the chair on the floor, making all the dimensions the same as here described; this enabled him to get all his lengths, curves and shoulders accurately. The seat and back were rebated on their inside

inner edges to receive the frame work for cushions made by his sister Amy.

Robert made a complete success of the work, and the gifts were fully appreciated by his uncle and aunt, and were prized much more than if they had been bought at a first-class furniture store.

Now there is no reason why some of our boys who possess a few tools should not follow the example of Robert and make up between this and the coming holidays something to give to their friends. It is not necessary that they should all make picture frames or chairs, there are hundreds of other little things they may make, such as wall brackets, hanging cabinets, card baskets, foot stools, toilet stands, work-boxes, window cornices, spool stands, jewel cases, pen-holders, photo-frames, towel-racks, etc.

Wall and corner brackets may be made of plain pine boards, with but little ornamentation; they may be stained or simply varnished and then handed over to the girls to drape with fringes, knitted or embroidered work.

A very pretty and inexpensive toilet stand, suitable as a gift to a lady friend, may be made by using an old four-legged stand, or by making a rough stand, or by using a dry-goods box of the right dimensions. Cover the top with cambric, blue or pink. Draw this over it nicely and tack it firmly round the edge, then take a piece of cambric, same color, and long enough to go around three sides and wide enough to reach from the top of stand to the floor. Cut a piece of cheese cloth twice the length of the cambric and the same width, and allow an inch and a half for hem. Fell the edge opposite the hem and tuck under the edge of the stand. Finish the edge and just above the hem with a notched box plaiting about two inches wide of the cambric covered with the cheese cloth and nail in place with bright headed tacks. The effect, when finished is quite pleasing.

There are many other things that might be treated in this simple way; for instance, a small box whose dimensions are about twelve inches long, eight wide and from six to eight inches high, could be made into a very handsome footstool.

Boy Inventors.

THE *Christian Advocate* justly considers that a boy's elders are guilty of a foolish act when they snub him because he says or does something which they don't understand. A boy's personality is entitled to as much respect as a man's, so long as he behaves himself. In the following anecdotes wise and foolish elders are exhibited—one class respecting, and the other despising a boy.

Some of the most important inventions have been the work of boys. The invention of the valve motion to the steam engine was made by a mere boy.

Newcomen's engine was in a very incomplete condition, from the fact that there was no way to open or close the valves, except by means of levers operated by hand.

He set up a large engine at one of the mines, and a boy, Humphrey Potter, was hired to work these valve-levers; although this is not hard work, yet it required his constant attention.

As he was working the levers he saw that parts of the engine moved in the right direction, and at the same time that he had to open or close the valves.

He procured a strong cord, and made one end fast to the proper part of the engine, and the other end to the valve-lever; and the boy then had the satisfaction of seeing the engine move with perfect regularity of motion.

A short time after the foreman came around and saw the boy playing marbles at the door. Looking at the engine he saw the ingenuity of the boy, and also the advantage of so great an invention. The idea suggested by the boy's inventive genius was put in a practical form, and made the steam engine an automatic working machine.

The power loom is the invention of a farmer's boy who had never seen or heard of such a thing.

He whittled one out with his jackknife, and after he had got it all done, he, with great enthusiasm, showed it to his father, who at once kicked it to pieces, saying he would have no boy about him that would spend his time on such foolish things.

The boy was sent to a blacksmith to learn a trade, and his master took a lively interest in him. He made a loom of what was left of the one his father had broken up, and showed it to his master.

The blacksmith saw he had no common boy as an apprentice, and that the invention was a valuable one. He had a loom constructed under the supervision of the boy. It worked to their perfect satisfaction, and the blacksmith furnished the means to manufacture the looms, and the boy received half the profits. In about a year the blacksmith wrote to the boy's father that he should bring with him a wealthy gentleman who was the inventor of the celebrated power loom.

You may be able to judge of the astonishment at the old home when his son was presented to him as the inventor, who told him that the loom was the same as the model that he had kicked to pieces but a year ago.

Our Patent Office shows many ingenious and useful inventions made by minors and women, and the above list of important inventions made by boys might be largely increased did space permit.

Although the foregoing is not strictly in accordance with facts, it offers food for thought for the boys, as it indicates what might be done by those of an ingenious turn of mind and who receive fair encouragement from their parents and friends. We have often seen young folks, both boys and girls, who have been brought to their "wits end" in some little matter suddenly get out of the difficulty, by devising some before unknown means, thus proving that there is some truth in the old adage that "necessity is the mother of invention," but in the main it is better for boys to understand that no great invention is ever likely to be made without thought and proper preparation. Work is the only certain road leading to success in invention, as it is in obtaining knowledge.

— A teaspoonful of salt to a quart of the soil in plant boxes will kill the white worms.

Marvels of Pond Life.—XIV.

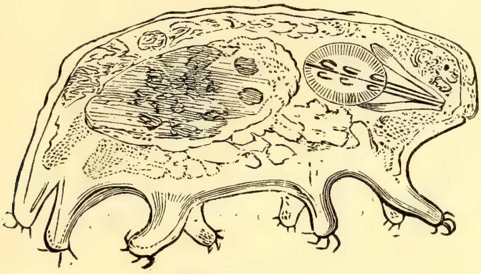
THERE is always satisfaction in finding a work accomplished; but the attempt to delineate some of the marvels of minute creation has been a pleasant one, and we approach the completion of our task of recording a *Microscopic Year* with something like regret. The dark, dirty December of the great metropolis may not seem a promising time for field excursions, but some ponds lie near enough to practicable roads and paths to render an occasional dip in them, not of ourselves, but of our bottles—an easy and not unpleasant performance; and if the weather is unusually bad, we can fall back upon our preserves in bottles and tanks, which seldom fail to afford something new, as we have been pretty sure to bring home some undeveloped germs with our stock of pond-water and plants, and even creatures of considerable size are very likely to have escaped detection in our first efforts at examination.

When objects are not over abundant, as is apt to be the case in the cold months, it is well to fill a large vial with some water out of the aquarium or other large vessel, and watch what living specks may be moving about therein. These are readily examined with a pocket-lens, and with a little dexterity any promising creature can be fished out with the dipping-tube. It is also advisable to shake a mass of vegetation in a white basin, as the larger infusoria, etc., may be thrown down; and indeed this method (as recommended by Pritchard) is always convenient. Even so small a quantity of water as is contained in a glass cell, appropriated to the continual examination of polyps or polyzoa, should be frequently hunted over with a low power, as in the course of days and weeks one race of small animals will disappear, and another take their place.

Following these various methods in December, we obtained many specimens; but the most interesting was found by taking up small branches of the Anacharis with a pair of forceps, and putting them into a glass trough to see what inhabitants they might possess. One of these trials was rewarded by the appearance of a little puppy-shaped animal very busy pawing about with eight imperfect legs, but not making much progress with all his efforts. It was evident that we had obtained one of the *Tardigrada* (slow-steppers), or Water-Bears, and a very comical amusing little fellow he was. The figure was like that of a new-born puppy, or "unlicked" bear cub; each of the eight legs were provided with four serviceable claws, there was no tail, and the blunt head was susceptible of considerable alteration of shape. He was grubbing about among

some bits of decayed vegetation, and from the mass of green matter in his stomach it was evident that he was not one of that painfully numerous class in England—the starving poor.

A power of one hundred and five linear, obtained with a two-thirds object-glass, and the second eye-piece, enabled all his motions and general structure to be exhibited, and showed that he possessed a piece or pieces, are protrusile. They were frequently brought as far as the outer lips (if we may so call the margins of the mouth), but we did not witness an actual protrusion, except when the lips accompanied them, and formed a small round pouting orifice. The skin of the animal was tough and somewhat loose, and wrinkled during the contractions its proprietor made. The interior of the body



Water-Bear.

sort of gizzard, whose details would require more magnification to bring out. Accordingly the dipping-tube was carefully held just over him, the finger removed, and luckily in went the little gentleman with the ascending current. He was cautiously transferred to a Compressorium,* an apparatus by which the approach of two thin plates of glass can be regulated by the action of a spring and a screw; and just enough pressure was employed to keep him from changing his place, although he was able to move his tiny limbs. Thus arranged, he was placed under a power of two hundred and forty linear, and illuminated by an achromatic condenser,† to make the fine structure of his gizzard as plain as possible. It was then seen that this curious organ contains several prominences or teeth, and is composed of muscular fibres, radiating in every direction. From the front of the gizzard proceed two rods, which meet in a point, and are supposed to represent the maxillæ or jaws of insects, while between them is a tube or channel, through which the food is passed. The mouth is *suctorial*, and the two horny rods, with their central

exhibited an immense multitude of globular particles of various sizes in constant motion, but not moving in any vessels, or performing a distinct circulation.

My specimens had no visible eyes, and these organs are, according to Pritchard's book, "variable and fugacious." The same authority remarks, "In most vital phenomena they very closely accord with the rotatoria; thus like these they can be revived after being put into hot water at 113° to 118°, but are destroyed by immersion in boiling water. They may be gradually heated to 216°, 252°, and even 261°. It is also by their capability of resuscitation after being dried that they are able to sustain their vitality in such localities as the roofs of houses, where at one time they are subjected to great heat and excessive drought, and at another are immersed in water."

When vital processes are not stopped by excess of temperature, as is the case with the higher animals, the power of resisting heat without destruction depends upon the condition of the albumen. Soluble albumen, or, as it should be called, *Albuminate of Soda* (for a small quantity of that alkali is present and chemically united with it), after having been *thoroughly dried*, may be heated without loss of its solubility; although if the same temperature was applied before it was dry, that solubility would be destroyed, and it would no longer be a fit constituent of a living creature. As Dr. Carpenter observes, this fact is of much interest in explaining the tenacity of life in the Tardigrada.

The movements of the water-bears, al-

* The best forms of this instrument are made by Messrs. R. & J. Beck, the glass plates being held in their places by flat-headed screws, and not by cement. This plan was devised by the author, and makes it easy to renew the glasses when broken.

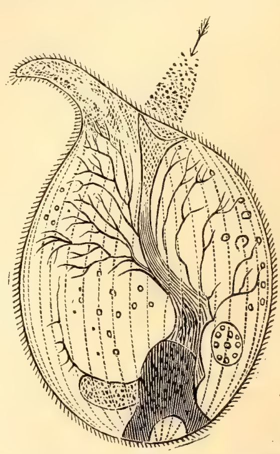
† The achromatic condenser is a frame capable of supporting an object glass lower than that employed for vision, through which the light passes to the object in quantities and directions determined by stops of various shapes. The appearances mentioned can be seen without it, though not so well.

though slow, evince a decided purpose and ability to make all parts work together for one common object; and as might be expected from this fact, and also from the repetition of distinct, although not articulated limbs, they are provided with a nervous apparatus of considerable development, in the shape of a chain of a ganglia and a brain, with connecting filaments. From these and other circumstances naturalists consider the Tardigrada to belong to the great family of *Spiders*, of which they are, physiologically speaking, *poor relations*. Siebold says "they form the transition from the Arachnoidæ to the Annelides."* Like the spiders they cast their skin; and, although I was not fortunate enough to witness this operation—called in the language of the learned *ecdysis*, which means putting its clothes off—I found an empty hide, which, making allowance for the comparative size of the creatures, looked tough and strong as that of a rhinoceros, and showed that the stripping process extended to the tips of the claws. The 'Micrographic Dictionary' states that the Tardigrada lay but few eggs at a time, and these are "usually deposited during the ecdysis, the exuviæ serving as a protection to them during the process of hatching." Thus Mrs. Water-Bear makes a nursery out of her old skin, a device as ingenious as unexpected. The water-bears are said to be hermaphrodites, but this is improbable.

The *Plumatella repens*, described in a former chapter, was kept in a glass trough, to which some fresh water was added every few days, taken from a glass jar that had been standing many weeks with growing anacharis in it. One day a singular creature made its appearance in the trough; when magnified sixty diameters it resembled an oval bladder, with a sort of proboscis attached to it. At one part it was longitudinally constricted, and evidently possessed some branched and complicated internal vessel. The surface was ciliated, and the neck or proboscis acted as a rudder, and enabled the creature to execute rapid turns. It swam up and down, and round about, sometimes rotating on its axis, at others keeping the same side uppermost, but did not exhibit the faintest sign of intelligence in its movements, except an occasional finger-like bend of the proboscis, upon which the cilia seemed thicker than upon the body. It was big enough to be observed as a moving white speck by the naked eye, when the vessel containing it was held to catch the light slantingly; but a power of one hundred and five was conveniently employed to enable its structure to be discerned. Under this power, when the animal was resting or moving slowly, a mouth was perceived on the left side of the proboscis, which was usually, though not always, curved to the right. The mouth was a round or oval orifice, and when illuminated by the parabola, its lips or margin looked thickened, and of a pale blue, and ciliated, while the rest of the body assumed a pinkish pearly tint.

Below the mouth came a funnel-shaped tube or œsophagus, having some folds or plaits on its sides, and terminating in a broad digestive tube, distinct from the nucleus, and ramifying like a tree. The constriction before mentioned, which was always seen in certain positions, although it varied *very considerably* in depth and width, drew up the integument towards the main trunk of the digestive tube, and thus the animal had a distinct ventral and dorsal side. The branches of the tube stopped somewhat abruptly just before reaching the surface, and were often observed to end in small round vacuoles or vesicles.

At the bottom of the bladder, opposite the mouth, in some specimens were large round cavities or cells, filled with smaller cells, or partially transparent granules. These varied in number from one to two or three, and were replaced in other specimens by masses that did not present the same regular form or rounded outline. In one instance an amorphous structure of this kind gradually divided itself, and seemed in the course of forming two cells, but the end of the process was unfortunately not seen. The annexed



Trachelius ovum (slightly flattened). × 105.

drawing will readily enable the animal to be recognized. It shows the mouth very plainly, and a current of small particles

* 'Anatomy of the Invertebrata,' Burnett's trans., p. 364.

moving towards it. The œsophagus terminates in a digestive tube, like the trunk of a tree, from which numerous branches spring. This arrangement is probably analogous to that of the phlebenterous mollusks described by Quatrefages, in which the ramifications of the stomach answer the purpose of arteries, and convey the nutrient fluid to various parts of the body. It is also likely that they minister to the function of respiration.

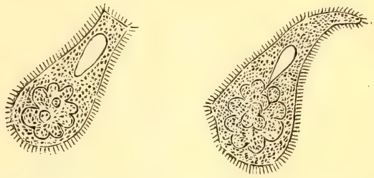
The cilia on the surface, which are arranged in parallel lines, are best observed when the animal is slightly flattened in a live-box; but this process produces a considerabie derangement in the relative position of the internal parts, and they can only be well seen when it is immersed in plenty of water, and is polite enough to stand still, and submit his digestive economy to a steady gaze. The only way to succeed in this undertaking is to have a large stock of patience as well as a convenient cell or trough. The table must be kept steady, and the prisoner watched from time to time, and at last he will be found ready for display.

Pritchard says this animal, whose name is *Trachelius ovum*, is an inhabitant of stagnant bog water, and has been found encysted. My specimens could not be called plentiful, but for several weeks I could generally find two or three, by filling a four-ounce vial from the glass jar, and examining its contents with a pocket-lens. If none were present, another dip was made, and usually with success.

One evening I caught a good specimen by means of the dipping-tube, and cautiously let it out, accompanied by a drop of water, on the glass floor of the live-box. A glance with the pocket-lens showed all was right, and the cover was very gently put on, but it had scarcely touched the creature when it became crumpled up and in confusion. On one or two former occasions I had been unfortunate enough to give my captives a squeeze too much, with the usual result of a rupture of their integuments and an escape of globules and fluids from the regions within. Now, however, there was no such rupture and no such escape, but instead of a smooth, comely surface, my Trachelius had lost all title to his specific designation, *ovum*, for instead of bearing any resemblance to an egg, it was more like an Irishman's hat after having a bit of a "shindy" at Donnybrook Fair.

I was greatly puzzled with this aspect of things, and still more so when my deranged specimen twirled and bumped about with considerable velocity, and in all directions. Presently a decided constriction appeared about half-way below the mouth and proboscis, and in transverse direction. The ciliary motion became very violent in the lower half just below the constriction, while the proboscis worked hard to make its half go another way. For some minutes there was a tug of war, and at length away went proboscis with his portion, still much crumpled by the fight, and left the other bit to roam at will, gradually smooth his puckers, and assume the appearance of a respectable well-to-do animalcule.

Three hours after the "fission" the proboscis half was not unlike the former self of the late "entire," but with diminished body and larger neck; while the remaining portion had assumed a flask form, and would not have been known by his dearest acquaintance. The portraits of the *dis-United States* were quickly taken, and, as bed-time had arrived, they



Trachetius ovum, three hours after division. $\times 60$.

were left to darkness and themselves. The next morning a change had come over the "spirit of their dream." Both were quiet, or sedately moving, and they were nearly alike. The proboscis fellow had increased and rounded his body, and diminished his nose; while Mr. Flask had grown round also, and evinced an intention of cultivating a proboscis himself. Twenty-seven hours after the separation, both had made considerable progress in arranging and developing their insides, which had been thrown into great confusion by the way in which the original animal had been wrenched in half, and in both a granular mass was forming opposite the mouth end. The proboscis portion, which may perhaps be termed the *mother*, was more advanced than her progeny, but both had a great deal to do if they meant to exhibit the original figure, and develop a set of bowels as elegantly branched. Whether they would have succeeded or not under happier circumstances I cannot tell, but unfortunately the Fate who carries the scissors cut short their days.

In all other animalcules in which I had observed the process of multiplication by self-division, it seems to go on smoothly, and with no discomfort to either the dividend or the quotient, and it may be that in the fission of the *Trachelius ovum* I witnessed what the doctors would call a bad case. Indeed it may have been pre-

maturely brought on, and aggravated by the squeeze in the live-box. It is, however, probable, from the stronger texture and greater organic development of this animalcule, that it does not divide so easily as the softer and simpler kinds.

Frequent examination of this animalcule has created a strong doubt in my mind whether it is rightly placed in our "systems." My own impression is that it belongs to a higher class.

Feather Cloth.

THIS novel and beautiful fabric is more and more prized as it becomes more widely known. Those of our readers who are familiar with the processes of ordinary cloth manufacture will appreciate the following description of the method of making feather cloth, which we take from the *Textile Manufacturer:*

The manufacture of feather cloth is not difficult, and the machines used in an ordinary woolen mill are suitable for the purpose with but slight modifications. When the down has been pulled off the feathers it is ready to be mixed with any textile material, such as cotton, silk, or wool, but the latter is the most suitable on account of its softness. Down may even be spun by itself, but this is seldom done. The mixture most to be recommended is 70 lbs. to 80 lbs. down, 100 lbs. to 120 lbs. olein, wool 40 lbs. to 60 lbs. To unite these three they are placed in alternate layers upon each other on a floor, and are then passed through a cock heel willy, making 400 to 500 turns per minute, and then brought to the scribbler. The main cylinder of this engine should run only about 35 to 45 revolutions per minute, instead of 100 to 110 as with pure wool. All rollers, clearers and doffer must be speeded in proportion. India rubber clothing is the best for this work, and must not be too fine, while the rollers should be set pretty close. When passing out of the scribbler the mixture is allowed to fall on the floor, and removed by a girl to the carding engine. In doing this the attendant examines the mixture a little to remove any whole feathers which may have passed.

The carding engine runs at the same speed as the scribbler, and is, in other respects, like it. The mixture does, however, not fall on the floor, but is passed on a sheet of cotton cloth, which is rolled up behind the engine, and rolls up the lap coming from it, so that the latter remains perfectly separated, and cannot be compressed.

— Flour dusted on cabbages when the dew is on, will kill off cabbage worms. Probably by closing the pores of the worms.

A River of Hot Water.

The great Sutro Tunnel, cut to relieve the celebrated Comstock mines at Virginia City, Nevada, of vast quantities of hot water which is encountered in them, affords an outlet of 12,000,000 tons every twenty-four hours. Some of the water, as it finds its way into the mines, has a temperature of 195 degrees, while four miles from the mouth of the tunnel the temperature ranges from 130 degrees to 135 degrees. To obviate the inconvenience which would arise from the vapor such a vast quantity of water would give off, the flow is conducted through the entire tunnel, four miles, in a tight flume made of pine. At the point of exit the water has lost but seven degrees of heat. Sixty feet below the month of the tunnel the hot water is utilized for turning machinery belonging to the company, from whence it is carried off by a tunnel 1,100 feet in length, which serves as a waterway. Leaving the wasteway tunnel, the water flows to the Carson River, a mile and a half distant. This hot water is being utilized for many purposes. The boys have arranged several pools where they indulge in hot baths. The miners and others use it for laundry purposes, and arrangements are being made whereby 1,000 acres belonging to the company are being irrigated. It is proposed to conduct the hot water through iron pipes beneath the surface of the soil, near the roots of thousands of fruit trees which are to be planted, and in a similar manner giving the necessary warmth to a number of hot-houses to be used for the propagation of early fruits and vegetables.

Curious Changes of the Planet Mars.

Astronomers have lately been much puzzled at certain remarkable changes that have been observed to be taking place on the surface of our neighboring planet Mars, and many speculations as to their real nature and significance have been ventured, though as yet they are mere vague guesses.

The changes here referred to first arrested the attention of astronomers at the time of the brilliant opposition of Mars in 1877, when his two satellites were discovered. It was then that the existence of a number of long, narrow streaks, forming a sort of network over his surface, was also discovered. At the subsequent opposition of 1879–80, Prof. Schiaparelli, Director of the Observatory of Milan, detected these same long, narrow streaks crossing the Martian disk in all directions, and which, bearing more resemblance to canals than anything else, have since been so designated. These canals Schiaparelli carefully examined, and made accurate drawings of them.

At the opposition of 1881-82, Schiaparelli again had an opportunity of making an examination of this remarkable feature of the Martian topography, and made some discoveries concerning them that are both curious and astonishing. He found, in the case of many of the canals of which he had made faithful drawings during his earlier observations, that they had become divided and subdivided by a number of parallel lines running through them.

The most singular discovery is yet to be named. He was enabled to actually observe the progressive development and duplication of these canals in about twenty instances, between the 19th of January and the 24th of February.

From the eminence of the observer there can be no doubt of the entire reliability of these astonishing observatlons. Schiaparelli has noticed other changes going on on the surface of our neighbor planet—notably, a considerable enlargement of one of the supposed oceanic bodies of Mars, known to astronomers as the Kaiser Sea, and the variable brightness of certain other regions.

The next opposition of Mars, which will take place on the 31st of January, 1884, will be anticipated with much interest by astronomers. Some of the great telescopes, now in the course of construction, will by that time have been completed and erected, and, in the hands of distinguished astronomers, it may be that the nature of the mysterious and pronounced changes now taking place on Mars may be unravelled. As they concern the celestial body, which, next to our own satellite, is nearest to the earth, the phenomena above noticed have universal interest.

Cold Gold Plating.

We give the following, which professss to be taken from the *Uhrmacher Zeitung* as a fair sample of many of the recipes which find a place in the so-called technical journals:

Silver, German silver, copper, brass, and pinchbeck will each take a fine plating and polish by the following method, requiring neither heat nor electricity during the operation.

To prepare the gold powder, dissolve some pure gold in nitro-muriatic acid until the acid becomes so saturated with the metal that it ceases to absorb it; then soak up the liquid with fine linen rags, lay them aside till thoroughly dried, when they should be lighted and allowed to consume themselves quietly to ashes. In this way you procure pure gold in the finest possible powder.

If you wish to have your plating of a reddish tinge, copper must be added to the solution in the proportion of six parts gold to one part pure copper, dissolved in sixteen parts nitro-muriatic acid, dried and burned on linen rags as just described.

The article to be plated must be carefully cleansed and smoothed before commencing the operation. Then hold the end of a smooth cork an instant in the flame of your lamp, dip it in vinegar or salt and water, and apply the gold powder with it to the metallic surface to be plated, rubbing it in with care and energy until the coating of gold is of the required thickness.

Polish with a piece of manganese, or a burnisher wet with soft water in which a little soap has been dissolved. In performing this operation great care must be taken not to allow the acid to touch the hands, especially if there is any bruise or scratch upon them.

This recipe has been extensively copied, and always without a word of comment, and yet any person having the slightest knowledge of chemistry must know that it will not work. The process consists simply in preparing very finely divided metallic gold, but every one knows that this will not adhere to copper or brass by simple friction. The addition of a little mercury so as to form an amalgam, and the subsequent removal of the mercury by heat would convert it into a very fair recipe.

Practical Hints.

The longest span of wire in the world is used for a telegraph in India over the river Kistnah. It measures more than 6,000 feet and is stretched between two hills, each of which is 1,200 feet high.

Adhesive Cement.—Intimately mix finely-pulverized gum arabic with its weight of very finely powdered calcined alum. When mixed with a small quantity of water, it forms a cement which unites wood, paper, porcelain, glass and crockery very firmly. Must be kept dry in powder, and moistened only as needed.

Removing Grease from Bird Skins.—Although it is not an easy task to remove grease either from the inside or outside of a bird skin, yet it can be accomplished by the following methods, seconded with a little patience: If the inside is greasy sprinkle liberally with plaster of Paris, and scrape with a blunt knife, renewing the plaster from time to time so as to thoroughly absorb the grease. Should a bird's feathers be greasy—and in a white bird the chances are nine to one that they will be—wash the greasy places freely with spirits of turpentine, and then pour on plaster, replacing it with fresh as soon as it has become saturated with turpentine, at the same time brushing and moving the feathers about in order that the plaster may penetrate. Finish by beating with a light, elastic stick to remove all the plaster. As may be supposed, this is a somewhat tedious process, especially if the bird be large, but the results are excellent and well worth the trouble. The best time to cleanse a bird that is being mounted is after it has been wired and sewed up, but before placing on a perch.

EXCHANGES.

Only those who are *yearly* subscribers, and whose names are entered on our books have the privilege of inserting exchanges.

Exchanges must be on separate slips of paper or postal cards. If mixed with business matter in letters or cards they are filed away and never reach the printer.

Exchanges must not exceed thirty words.

Buying and selling belong to the advertising department.

We reserve the right to omit the exchange column, when we have not room for it, and the amount of space at our disposal will regulate the number of insertions given to each *exchange*, the preference being always given to those who have not previously used our columns.

Wanted engraver's tools with book of instructions, for a Victor Press, with cabinet, 2 type cases, type, ink roller and furniture complete; perfectly new. L. Warren, 72 Cumberland St., Brooklyn, N. Y.

A Fletcher Foot-Blower, cost $5, as good as new; will exchange for a Cushman, 2 in. or up scroll chuck, or other make; will give a satisfactory trade on the difference in price, if any. Louis Lutz, St. Clair Street, Toledo, O.

I have a lot of "Galaxy" (magazines) which I would like to exchange for an air rifle in good condition, a collection of birds' eggs, or offers. W. B. Greenleaf, 480 La Salle Ave., Chicago, Ill.

I have a Mechanical Telegraph with book of instructions, books, etc., which I wish to exchange for good microscopical objects, mounted on 3 x 1 slips. Address, with list, J. H. Frey, Millersburg, Ohio.

To exchange, "How to Use Microscope," Wells' "Natural Philosophy," and many other books, chemical apparatus, etc., for good photographic camera, and lenses. W. H. Weed, 254 Putnam Ave., Brooklyn, N. Y.

Wanted "Quimby's New Bee Keeping," for "Our Own Birds of the United States," by W. S. Baily; new. Joseph Anthony, Jr., Colota, Whiteside Co., Ill.

Wanted a good book in anatomy, in exchange for a book on chemistry, or for story books. A. G. G., Box 26, Summit, New Jersey.

A German-silver trimmed, patent lined, cocoa flute, cost $4, in good order, for good spy-glass, photo-material, or offers. Ewing McLean, Greencastle, Ind.

I have some fossil shells from the west bank of the Mississippi, to exchange for Indian relics. A. W. S., 187 E. 71st St., N. Y.

I have a magic lantern, Ruby pattern, nearly new, and 5 views; also "Our First Century," bound in leather, cost $7; state what is wanted in exchange. I. N. Spencer, Box. 217, So. Manchester, Conn.

First-class telegraph instrument and attachments, and "Wood's Botany," for bound volumes of periodicals, books, or offers. H. P. Albert, Anderson, Iowa.

Wanted a book on treatment and care of canary, also breeding of same; will give in exchange book named "Market Garden, Flower Garden and Bees," or 40 "Scientific Americans" or "Seaside Libraries;" want also old books. M. J. Mulvihill, Norwalk, Conn.

Coins, minerals, stamps, books, type, fishing tackle (very complete) and fish pole, bronze inkstand, etc., for coins, medals, stamps, war envelopes, old newspapers, and Continental, Colonial and Confederate currency. F. F. Fletcher, 103 Main St., St. Johnsburg, Vt.

Blow-pipe set (cost $10), large illustrated family Bible (cost $7.50), for Wood's Botany, Dana's Geology, or printing press and type. H. W. Noble, Box 134, South Dansville, N. Y.

Wanted, offers for fossil shells from the west coast of Africa. A. W. Seward, 187 E. 71st St.

I have a number of birds' eggs I should like to trade for other birds' eggs; send for list of trading eggs. A. G. G., Box 26, Summit, New Jersey.

For a microscope stand or offers, a 36-inch turning lathe (new) and a number of scientific books; send for list. A. Kendall, Somerville, Mass.

Wanted services of amateur printer with small office (or large), in exchange for an interest in a well-established weekly paper, good size. Eagle Office, Plymouth, N. H.

American Agriculturist microscope, new, cost $15, for amateur photographic apparatus, lever watch, 22 calibre breech-loading sporting rifle or magic lantern of equal value. Wm. A. Walker, Rockland, R. I.

I. T. Bell, Franklin, Pa., has back numbers of Scientific American, Forest and Stream, and Young Scientist, good flute, chessmen, books, etc., for good magic lantern, revolver, scarce coins, or offers.

A steel spring bracket-saw, 2 doz. saw blades, and about 1 doz. patterns for a good stylographic pen or offers; send postal before exchanging. Geo. Oakley, Rutherford, N. J.

A rosewood banjo, 11 inch head, 12 nuts, fully strung, together with lot of dime banjo music and instructions, for microscope, Webster's Unabridged, monkey, squirrel and cage, or offers. J. DeWitt Clark, P. O. Box 37, Brooklyn, N. Y.

For self-inking printing press and type, one Henry rifle, 16 shot, 44 cal., cost $40, in good order, or one double barrel shot gun, barrels London fine twist, or offers. J. B. Garrison, Belton, Bell Co., Texas.

What offers for "The Chefs D'Oeuvre D'Art, Paris Exhibition 1878," cost $16, good as new, bound; 1 large photo camera, complete, cost $95; Scientific American from 1859 to 1880, 4 vols. bound. D. Keesler, Stony Point, N. Y.

Sea shells of Atlantic coast, scientifically marked, for books, old or new magazines, Indian relics, natural history specimens, apparatus; anything. Wilfred Leon Miller, P. O. Box 392, Cape May, N. J.

A new 40 diameter microscope, corals, and minerals, for a stylographic pen, air gun, or offers. J. McBride, 54 Garley St., Chicago.

A dulcimer that cost $20, books and fossils, for a telescope, microscope, fossils, Indian relics, or offers. E. J. Votaw, Salem, Iowa.

A self-inking model press, 5 x 7½, cost $23; $90 worth of scroll-saw designs in lots to suit; Scientific American, 1880; Palliser's Useful Details, $3; for photo outfit or offers. C. H. Parker, Coldbrook Springs, Mass.

Telegraph key and sounder, Frank Leslie's Illustrated Magazines, mounted microscopic objects, natural curiosities, for bull's-eye condenser, photograph camera, Unabridged Webster Dictionary, or offers. W. T. Alan, Greenville, Mercer Co., Pa.

Large magic lantern, spectroscope, pantagraph, for enlarging drawings, rosewood writing desk, man's saddle, for microscope, photo outfit or offers. Thomas Walters, Bergen St., East of Brooklyn Ave., Brooklyn, N. Y.

Model card press, chase 3¼ x 5¼, with 4 fonts type, cases, etc., for good foot lathe. Mills Day, 2 Farmington Av., Hartford, Ct.

French microscope, inclines to any angle, delicate fine motion, neat upright case, cost $17.50, for scientific books; send list to W. Fitz, P.O. Box 2852, New York.

Wanted, Quinby's New Bee Keeping, for Our Own Birds of the United States, by W. S. Baily; new. Joseph Anthony, Jr., Coleta, Whiteside Co., Illinois.

Printing type, small pica; large and small capitals, and small letters; 60 to 65 lbs., including two large cases; also gothic nonpariel, for trade. J. Siler, 1242 Broadway, St. Louis, Mo.

One years' copy of Aldine, cost $5.50, and German accordion, with instructions how to use it, cost $5.00, for offers. Chas. Dempwolf, 86 Benson St., Paterson, N. J.

A Novelty printing press, with type, prints a form 5 x 7 inches, cost $40.00, for a microscope, photographic apparatus, or offers. T. W. Patterson, Warsaw, N. Y.

$80 worth of (nearly new) printing material, minerals, fossils, Aboriginal relics, etc., for scientific books, good American watch, and offers. F. M. Farrell, Cobden, Union Co., Ills.

Rocks, minerals, fossils and fresh water shells for microscope stand, $20 to $75, also for objectives, turning lathe type, and tools. D. D. Babcock, South Dansville, N. Y.

Magic lantern, in good order, condensing lens, 2½ in. diameter, 8 slides. For small photographic camera or offers. H. A. Giddings, 4 Union Place, Classon Ave., Brooklyn.

The Young Scientist

SCIENCE IS KNOWLEDGE. KNOWLEDGE IS POWER.

A PRACTICAL JOURNAL OF

HOME ARTS.

VOL. V. NEW YORK, NOVEMBER, 1882. No. 11.

Scroll-Sawing Woods.

MANY of our best scroll sawyers seldom use more than two kinds of wood, black walnut and white holly, and now and again cherry and butternut. These woods, of course, are all very well, and by a proper harmonization may be made to appear very handsome when worked together. These varieties, however, do not exhaust the list of woods suitable for the scroll-saw outfit. True, black walnut and holly rate very high, both on account of their colors and fine qualities, but we must say that oak or ash might frequently be used in place of the lighter wood, where a strong contrast is not needed. Holly is very nice for card baskets, small photo frames, silhouettes, or mottos, but is not adapted for large baskets, cabinets, or other large work. Indeed, holly soon loses its fine creamy-white color if it is left exposed to the air for any length of time, and then looks like basswood or poplar. Brackets should be made of walnut, oak, or mahogany, and mottos of holly; and when the latter is nicely glued on a dark ground of fine black walnut, and surrounded with an appropriate frame, it shows that the maker—to my mind—possessed a proper sense of the "fitness of things."

Flies and dust are among the worst enemies of fret work, and it does seem as though they preferred to roost on white holly more than on any other wood. The white wood may be protected some little by varnishing it with a coat of bleached shellac before it is cut. It would also be well to use thin pieces of basswood, pine, or other cheap soft wood on each side of it, the upper one to paste the pattern on, the lower one to prevent any beard from forming on the holly. The three pieces should be tacked together with the holly in the centre, of course. When fret work is cut this way it saves time, as no sand-

papering is necessary, and the finest and most complex pattern may be cut out with great ease. Under no consideration whatever should common varnish or oil be used on holly; it would spoil the whole work.

While it is sometimes necessary to use glue in putting holly work together, it is better, when possible, to use fine screws; but when glue must be used, the whitest kind should be employed. Unless the sawyer is a pretty good hand at cutting, he should not undertake to make intricate work in holly, but if the operator is certain he can finish what he undertakes, then we say "go ahead;" but he should not tire himself the first day, or work hard for a week and then drop off for six months. It is best to "make haste slowly" and persistently until the work in hand is fully completed.

Holly grows plentifully in South America, mostly in swampy situations; also in Nepaul, Japan, and some other parts of the world. The name holly is said to be derived from the use of the branches and berries to decorate churches at Christmas, from which the tree was called Holy tree.

Black walnut is an excellent wood for the sawyer, and always looks best when about one-quarter of an inch thick. It works easily, is not liable to chip, is cheap, easily polished or oiled, and does not look dirty nearly so soon as many other woods. There are nearly thirty varieties of walnut known, mostly natives of America. It is also a native of Persia, India, some parts of Africa, and Europe. The Romans were well acquainted with it, and it was cultivated in forests as early as Tiberius. The walnut of our own country is the largest and handsomest of them all. Sometimes it reaches the enormous dimensions of six or seven feet in diameter at the trunk.

Oak or ash, when used by the sawyer, should never be less than three-eighths of an inch thick. These woods should be varnished, never oiled. They both darken with age, particularly oak, which soon assumes a fine dark color that gives it a rich and valuable appearance.

Novel Method of Exhibiting Native Woods in the Drawing Room.

BY F. B. BROCK.

DURING a recent visit to the National Museum at Washington, now in the course of being fitted up for the reception of curiosities and other things pertaining to a museum, I was much interested in a collection of ornamental woods from Japan—a gift from the University of Tokio. This collection embodies so much originality and attractiveness combined, with simplicity in the manner of its exhibition, that I cannot refrain writing you on the subject in the hope that some who read this, and whose accomplishments are such as to permit them to indulge the art, may be enabled to beautify their homes without any expense, other than loss of time.

This Japanese collection consists of a series of panel frames 8 x 12 inches each, a panel being devoted to each variety of wood. The general appearance of the panel is shown by the subjoined sketch. The panel, A, proper is a thin planed surface ($\frac{1}{8}$ in. thick) and, in this collection, is unpolished, though it is obvious that a polish may be given to the wood. When the diameter of a tree is less than eight inches two or more pieces are laid side by side to give the requisite width. In the sketch here given the panel is in four pieces, the division lines being indicated in the drawing. The frame, B, of the panel is cut from the same wood, an inch in width by one-half inch in thickness. The face width of the frame, B, is left with the bark on, in order to show its formation, and it also forms a pleasing contrast to the panel. At the four corners of the frame are transverse sections, C, of the same species of wood of the same depth ($\frac{1}{2}$ in.) as the frame, B, and lying flush therewith. These sections, C, must be cut from a small limb of the tree, which should be approximately an inch and a half in diameter. Their faces should be sandpapered or polished.

The artistic preparation of the panel is next in order. It consists in painting, in oil or water colors, a twig and specimen leaves of the same tree from which the

framed panel has been made. If the tree flowers, as most of the ornamental trees do, the bud, the blossom, and the seed should be shown by detail views on the panel. Some trees, as the locust, bear seed pods, and these form pleasing subjects to put upon the panel. In case of fruit or nut-bearing trees, the specimen fruit and nut may be painted. Even the bugs or worms which infest the tree may appropriately appear.

The name and genus of the tree is provided for in the space marked D, which, in the sketch, is filled by Japanese characters.

In this manner it is possible for the owner of a rural home, with some experience in water or oil colors, to become possessed of beautiful panels of every kind of wood growing on his place and those out of it. They are appropriate for the drawing-room, and form unique and interesting subjects. In the museum they are grouped together in handsome cases, where they are much admired.—*Builder and Wood-Worker.*

Animal Intelligence.

A GREAT many very amusing and interesting stories are told of animals, birds and insects, some of which would lead us to suppose that the animals possessed an intelligence much higher than is usually attributed to instinct. Take, for instance, the conduct of the mason wasp, or carpenter bee, when building her nest. She has had no individual experience; the nest is her first effort, and she never survives to build another. She

never saw her parents, who must have perished before she issued from the egg. Her mate and any other of her own species whom she may have seen are exactly in the some position as herself, yet she proceeds with all due dignity, and constructs her nest with a regularity and completeness that is amazing. The mother first cuts a canal of suitable dimensions in a log of timber, especially when partly decayed; she then lays an egg at the end of the hole, and places near it a mass of pollen and honey, as food for the future larva. The egg and the food are then sealed up by a thin wall, made up of powdered wood and a secretion of the insect. In this manner the mother bee divides her house into little chambers, depositing an egg in each one. In due time the eggs hatch, and the larvæ devours the food left for them, and then pass into the chrysalis state. When the perfect insect is developed, it destroys the partitions and escapes into the open air, and proceeds to construct its nest, just the same as its mother did before it. Now how do these bees acquire the knowledge to construct their nests? This is a question that offers food for the advanced thinker.

Another curious thing is noticeable in the case of young pointer dogs, which goes to show that a peculiarity, not originally possessed by the breed, can be, and is, hereditarily transmitted to the exclusion of an instinctive quality.* These dogs, though they may never have had any previous training, when taken into a stubble field for the first time, act as though they had been taught to point at birds, as their parents had before them, but whose actions they had never seen, and whose natural instincts would lead them to rush at any small birds or beasts that might make their appearance. Here we have one instance where education or training is handed down from one generation to another.

According to a quotation made from an unpublished M.S. of the late Charles Darwin, "even the headless oyster seems to profit by experience. Disquemose records that 'oysters taken from a depth never uncovered by the sea open their shells, lose the water within, and perish; but oysters from the same place and depth, if kept in reservoirs, where they are occasionally left uncovered for a short time, and are otherwise incommoded, learn to keep their shells shut, and then live for a much longer time when taken out of the water.'" According to Bingley, this fact is turned to a practical account in the "oyster schools" of France: "The distance from the coast to Paris being too great for the newly-dragged oysters to travel without opening their shells, they are first taught in the schools to bear a longer exposure to the air without gaping, and when their education is complete, they are sent on to the metropolis, where they arrive with closed shells and in a healthy condition." Here we have an intelligence evinced by an animal of very low organization, for it is evident the oyster can modify its actions according to circumstances, so as to avoid inconvenience.

In ants we find a very high grade of mental power, and there is a superabundance of evidence that they possess fair memories. "It is well known that if a strange ant, even of their own species, is introduced into a nest, it is, as a rule, attacked at once and killed without mercy. But if some of the inmates of a nest are removed, and kept apart from their fellows, even for months, they are at once recognized when brought back to the community. It is an important fact that this recognition is not automatically invariable. When ants are removed in the pupa state, tended by strangers, and then restored, some, at least, of their relations, are certainly puzzled, and in many cases doubt their citizenship. We say some, because, while strangers under the circumstances would have been imimmediately attacked, these ants are in every case amicably received by a majority of the colony, and sometimes it takes several hours before they come across any one who does not recognize them."

As to the memory of ants for direction and locality, many of the observations

*From "Animal Intelligence." By G. J. Romanes, F.R.S.

are open to doubt, as the rediscovery of an abandoned nest, may be accidental, as in a case mentioned by Belt. But Carl Vogt, in his "Thierstauten," mentions that "for several successive years ants from a certain nest used to go through several inhabited nests to a chemist's shop 600 yards distant, in order to obtain access to a vessel filled with syrup." This was continued for several seasons, thus showing that the ants remembered the syrup jar from year to year.

As a proof that ants have some means of communication among themselves, we have but to describe the experiment performed by Sir J. Lubbock: Three glasses were connected with a nest of black ants by means of three tapes, equal in length and width, and placed parallel with each other, so that the means of access from the nest to each glass were exactly equal. In one of the glasses were placed from three hundred to six hundred larvæ, in the second two or three only, and in the third none at all. The object of the last was to see whether any ants would arrive at the glasses by mere accident. The experimentalist then put a mature ant into each glass. Each of them took a larva and carried it to the nest, returning for another, and so on. After each journey another larva was put in the glass containing only a few larvæ. Sir J. Lubbock reasoned that if the ants came to the glasses as a matter of accident, or accompanied one another by chance, or if they merely saw larvæ being brought, and concluded that more might be found in the same place, or if the ants were merely guided by the scented track of their forerunners, the number of the ants going to each of the two glasses ought to be approximately equal. But this was not the case. To the glass containing many larvæ there came, in 47½ hours, 257 ants; to that with only two or three larvæ there came in a time longer by 5½ hours, only 82 ants; and to the glass containing no larvæ there came not one. Hence it is concluded that ants can not only tell their companions that work is to be done, but can give some idea of its quantity, and of the number of hands required for its performance. The precaution taken by Sir J. Lubbock, will, on careful consideration be found to exclude every other interpretation of the facts.

A Mr. H. L. Jenkins tells the following: "There are good reasons for supposing that elephants possess abstract ideas; for instance, I think it impossible to doubt that they acquire through their own experience notions of hardness and weight. The grounds on which I am led to think thus are as follows: A captured elephant, after he has been taught his ordinary duty, is taught to pick up things from the ground and give them to his mahout sitting upon his shoulders. For the first few months it is dangerous to require him to pick up anything but soft articles, because the things are often handed up with considerable force. After a time they appear to take in a knowledge of the nature of the things they are required to lift, and a bundle of cloths will be thrown sharply as before, but heavy things, such as a crowbar or iron chain, will be handed up in a gentle manner; a sharp knife will be picked up by the handle and placed on the elephant's head, so that the mahout can also take it by the handle. I have purposely given elephants things to lift which they could never have seen before, and they were handled in such a manner as to convince me that they recognized such qualities as hardness, sharpness, and weight."

Mr. Peal observed a young recently captured elephant, in Assam, pulling up and breaking some bamboo stakes, and carefully examining the pieces. "At last it seized one firmly in its trunk, and advancing its left foreleg firmly, passed the fragment of bamboo under the arm-pit, and began to scratch with some force. A large elephant leech soon fell to the ground, which, from its position, could not easily be detatched without this scraper, which had been deliberately made by the elephant." The narrator very truly says that these scrapers are *bona fide* tools, "intelligently made for a definite purpose." Here we have an instance of an animal making and using tools to accomplish an end that would otherwise have been left undone.

Fish Ponds.

To the formation of a fish pond a springy piece of ground, a large creek, or a small one, or any combination which will furnish a constant supply of fresh water, is a prerequisite.

By attaching a pump, propelled by the wind, to a well, you can supply a basin from fifty to seventy-five feet in diameter and six to eight feet deep, with water sufficient to raise several thousand carp, or other fish. The cost of this pond and appurtenances need not exceed fifty dollars, but excavations can be made to any extent to suit the taste or means of the owner. The dirt from these excavations should be removed far enough not to be washed back by rains. The bottom and sides need to be cemented or thoroughly puddled—that is made of good clear clay, moistened and well beaten. This will prevent the loss of water by leakage. When the basin is complete, place in it a small quantity of brush or floating weeds. A few trunks of trees, secured to the bottom, will afford a suitable hiding place for the fish, and will prevent marauders stealing the fish by netting. An outlet as well as an inlet for water should be provided, and proper screens be arranged so as to prevent the escape of fish. If you intend to raise carp, do not place other fish of a predatory character in the pond. The spawning will occur during the spring months, the female laying from 50,000 to 500,000 eggs. The eggs will adhere to whatever they touch, and will soon hatch. The green scum of a partially stagnant pond is fine food for the young fish. Mud in the bottom of the pond is beneficial. The fish will feed readily on kitchen-garden refuse, such as cabbage, leek, lettuce, hominy, or other substances.

Water seldom becomes too warm for these fish. During freezing weather, they bury themselves in the mud at the bottom of the pond. While in this condition, they should not be disturbed. In a pond of the given dimensions, several thousand fish have annually been taken. If weeds and grass grow profusely about the borders of the pond, so much the better for the fish. In two years time you can have an abundant and constant supply of sport and food, and the advantage of a pond, to assist in beautifying your home.

Col. Akers, the fish commissioner, of Tennessee, while visiting the pond of Messrs. Sprewitt & Co., captured a carp weighing over a pound and a half, and said the sport was as good and exciting as he wanted.

The kind of fish to stock the ponds with depends upon circumstances. If the pond is fed with abundant living springs and streams, if the water can always be kept clear and cool, trout are undoubtedly the best fish to obtain, in which case the bottom should be covered with coarse gravel or small stones, though this is by no means necessary.

How Closely Does a Machinist Measure?

In connection with the question of standard gauges and measuring instruments of perfection, it is interesting to notice how closely the machinist works with the *ordinary* tools of his trade.

Some little observation of a workman engaged in boring locomotive driving wheels and fitting shafts to them, led to to the following;

The wheels were bored with a tool, and of a taper of 1.64 inch in 7 inches. They were bored in a remarkably good lathe. but not to *exactly* the same size. A certain distance was fixed upon as proper for the wheel to be forced on the shaft, after allowing the shaft to settle into the wheel (which was laid down on the floor) by its own weight, and the workman would not make a variation of more than ⅛ inch in that distance.

Making allowance for want of truth in the hole and shaft (although it was extremely difficult to detect any variation), it is safe to say that the machinist was working within 1-4000th of an inch. To do this, he must first measure the hole in the wheel with his caliper, transfer that measure to another pair of calipers, and again transfer that measure to the shaft he was turning. Making allowance for the fact that a machinist cannot turn as fine as he can measure, it may be safely concluded that he will work so closely, that the variation will be scarcely noticeable in a fit. However closely he may work, the fact should not be lost sight of, that he cannot define the size to which he is working, without the use of some sort of a measuring instrument of perfection. In other words, he can work almost infinitely closer than he can measure, by the use of ordinary tools.—*American Machinist.*

Marvels of Pond Life.—XV.

THE creatures described in the preceding articles range from very simple to highly complicated forms, and in describing them some attention has been paid to the general principles of classification. The step is a wide one from the little masses of living jelly that constitute Amœbæ to the Rotifers, supplied with organs of sensation—eyes, feelers (calcars), and the long cilia in the Flosculariaus which seem to convey impression like the whiskers of a cat—together with elaborate machinery for catching, grinding up, and digesting their prey, and which are also well furnished with respiratory and excretory apparatus, ovaries, etc. In the polypi and polyzoa may be observed those resemblances in appearance which induced early naturalists to group them together, and also the wide difference of organization which marks the higher rank to which the latter have attained. Amongst the ciliated infusoria important gradations and differences will also be noticed, some having only one sort of cilia, others two sorts, and others, again, supplied, in addition to cilia, with hooks and styles. No perfectly satisfactory classification of the infusoria has yet been devised, and the life history of a great many is still very imperfectly known. On the whole, the tendency of research is to place many of them higher than they used to stand after Ehrenberg's supposition of their having a plurality of distinct stomachs, etc., was given up. Balbiani and others have shown numerous cases of their forming their eggs by a process analogous to that of higher animals. Some really are, and others closely resemble, the larval conditions of creatures higher in the scale, and the contracted vesicle with its channel bears resemblance to what is called the "water vascular system " of worms.

Zoological classification depends very much on morphology, that is, the tracing of particular structures, or parts, through all their stages, from the lowest to the highest forms in which they are exhibited. In this way the swimming bladder of a fish is shown to be a rudimentary lung, though it has no respiratory functions, and Mr. Kitchen Parker has found in the imperfect skull of the tadpole a rudimentary appearance of bones belonging to the human ear. The comparative anatomist, after a wide survey of the objects before him, arranges them in groups. He asks what are the characteristic things to be affirmed concerning all the A's that cannot be said of all the B's; or of all the C's that marks their difference from the A's or the D's. Careful investigation upon these methods shows affinities where they were not previously expected—birds and reptiles being close relations, for example, instead of distant connections—and they lessen the value for purposes of classification of peculiarities that might have been of the highest importance.

Professor Huxley divides the vertebrates into ITHYCOIDS, comprising fishes and amphibia, which besides other characteristics, have gills at some period of their existence; SAUROIDS (reptiles and birds), which have no gills. and possess certain developmental characteristics in common; and, lastly, MAMMALS. The Insecta, Myriopoda, Arachnidæ, and Crustacea, he remarks, "without doubt present so many characters in common as to form a very natural assemblage. All are provided with artificial limbs attached to a segmented body skeleton, the latter, like the skeleton of the limbs, being an 'exoskeleton,' or a bordering of that layer which corresponds with the outer part of the vertebrates. In others, at any rate in the embryonic condition, the nervous system is composed of a double chain of ganglia, united by longitudinal commissures, and the gullet passed between two of these commissures. No one of the members of these four classes is known to possess vibratile cilia. The great majority of these animals have a distinct heart, provided with valvular apertures, which are in communication with a perivisceral cavity containing corpusculated blood." These four classes have constituted the larger group or "province" of *Articulata* or *Arthropoda*. Professor Huxley thinks that, notwithstanding "the marked differences " between the Annelida (worms) and the preceding Arthropods (joints-foots), their resemblances outweighing them—the characters of the nervous system, and the frequently segmented body, with imperfect lateral appendages of the Annelida necessitates their assemblage with the Arthropoda in one great division, or sub-kingdom, of ANNULOSA.

Tracing analogies between Echinodermata (sea urchins, star-fish, etc.) and the Scolecida (intestinal worms), he places them together as *Annuloida*.

Cephalopoda, Pteropoda, Pulmo-gasteropoda, and Branchio-gasteropoda, having resemblances of nervous system, and "all possessing that remarkable buccal apparatus, the Odontophore," are placed together by him as ODONTOPHORA. The Odontophores (tooth-bearers) are familiar to microscopists as the so-called *palates* of mollusca. Placing with the above the lamellibranchial mollusks (mollusks with gills formed of lamellæ or little plates), Ascidioida (ascidians,) Brachiopoda (lampsheds), and Polyzoa, in spite of their differences, he forms another great group, ANNULOIDA.

The Actinozoa (anemones, etc.) and the Hydrozoa (polyps) constitute the CŒLENTERA of Frey and Leuckart. "In all these animals," says Professor Huxley, "the substance of the body is differentiated into those histological elements which have been termed cells, and the latter are previously disposed in two layers, one external and one internal, constituting the ectoderm and endoderm. Among animals which possess this histological structure the Cœlenterata stand alone in having an alimentary canal, which is open at its inner end and communicates freely by this aperture with the general cavity of the body," and "all (unless the Ctenophora should prove a partial exception to the rule) are provided with very remarkable organs of offence or defence, called thread-cells or nematocysts." In describing the Polyps we have given illustrations of these weapons.

The remaining classes, which have been roughly associated as *Protozoa*, must evidently be rearranged. Sponges, Rhizopods (Amœbæ, etc.), and Gregarines, have strong resemblances, but recent researches may place the former higher. The Infusoria comprehend creatures too various to remain under one head, and very many of them too highly organized to be called "protozoons," or first life-forms.

Those who wish to pursue this subject further may consult Professor Huxley's 'Elements of Comparative Anatomy,' from which the preceding quotations have been taken.

A system of classification founded upon anatomical and developmental considerations frequently differ considerably from one we might arrive at if all the creatures were arranged according to their faculties and the extent and accuracy of their relations to the external world. Such a classification would not in any way supersede the former, but it would prove very instructive and offer many valuable suggestions. Some years since, Professor Owen proposed to divide the Vertebrates according to the perfection of their brains, but other anatomists did not find his divisions sufficiently coincident with facts. Very little has been done towards an exact science of human phrenology. The difficulties remain pretty much as they were many years ago, and our comparative phrenology, if we may use such a term, is in a very imperfect state. When we come to the lower animals we do not know what peculiarities of the brain of an ant make it the recipient of a higher instinct, or give its possessor greater capacities for dealing with new and unexpected difficulties than are possessed by most other insects, and if any reader has a marine aquarium, and will make a few experiments in taming prawns, and watching their proceedings, he will discover symptoms of intelligence beyond what the structure of the creature would have led him to expect.

Animals usually possess some one leading characteristic to which their general structure is subordinated. Man stands alone in having the whole of his organization conformed to the demands of a thinking, ruling brain. To pass at once to the other extreme, we observe in the lower infusoria a restless locomotion, probably subservient to respiration, but utterly inconsistent with a well developed life of relation, or with manifestations of thought. The life of an animalcule may be summed up as a brief and restricted, but vigorous organic energy, and if the amount of change which a single creature can make in the external world, is inconceivably small, the labors of the entire race alter the conditions of a prodigious amount of matter. Microscopic vegetable life is an important agent in purifying water from the taint of decomposing organisms. By evolving oxygen it brings putrescent particles under the influence of a specific combustion, which, though slow, is as effectual as that which a furnace could accomplish. In this way minute moulds burn up decaying wood.

Microscopic animal life helps the regenerative process, and, together with the minute vegetable life, restores to the organic system myriads of tons of matter, which death and decay would have handed over to the inorganic world. In a very small pond or tank the quantity of this kind of work is soon appreciable, and if we reflect on the amazing amount of water all over the globe, including seas and oceans, which swarm with infusoria, the total effect produced in a single year must seem considerable, even when compared with that portion of the earth's crust that is subject to alteration from all other causes put together. If we add to the labor of the Infusoria those of other creatures whose organization can only be discovered by the microscope, and take in the foraminifera, polyps, polyzoa, etc., we shall have to record still larger obligations to minute forms of living things. The coral polyp builds reefs that constitute the chief characteristic of certain regions in the Pacific; foraminifera are forming or helping to form strata of considerable extent, while diatoms are making deposits many feet in thickness, composed of myriads of their silicious shells, or adding their contributions of silex, very large in the aggregate, to all sedimentary rocks. Testimony of this kind of work is found by the navigator who examines the ice in Arctic seas, and it comes up with soundings from the ocean depths.

On the surface of the earth the amount

of change produced is equally remarkable, although it leaves less permanent traces behind. As a rule no decomposition of organized matter takes place, no death of plants or animals, without infusorial life making its appearance, and disposing of no small portion of the spoils. Even in our climate the mass of matter thus annually affected is very large; but what must it not be in moist tropical lands, where every particle seems alive, and the race of life and death goes on at a speed, and to an extent scarcely conceivable by those who have not witnessed it.

Thus, if we look at the world of minute forms which the microscope reveals, there opens before us a spectacle of boundless extent. We see life manifested by the specks of jelly containing particles not aggregated into structure, and we see it gradually ascending in complexity of organization. In creatures whose habits and appearance seem most remote from our own, we find the elementary developments of the organs and powers that constitute our glory, and give us our power. Such studies assist us to conceive of the universe as a Cosmos, or Beautifully Organized Whole; and, although we cannot tell the object for which a single portion received its precise form, we trace everywhere relations of structure to means of existence and enjoyment, and are led to the conviction that all the actions and arrangements of the organic or inorganic worlds are due to a definite direction and co-ordination of a few simple forces, which implicitly and unerringly obey the dictates of an Omniscient Mind.

Simple Veneering with the Hammer.

THE following directions for veneering, if strictly followed, will insure success in this important branch of mechanical work.

The softest woods should be chosen. Perhaps the best for the purpose are those of perfectly straight grain and without a knot; of course don't attempt to veneer over a knot. Hard wood can be veneered, boxwood with ivory for instance, but wood that will warp and twist, such as cross-grained mahogany, must be avoided. The veneer and the wood on which it is to be laid must both be carefully prepared, the former by taking out all marks of the saw on both sides with a fine toothing plane, the latter with a coarser toothing plane. If the veneer happens to be broken in doing this, it may be repaired at once with a bit of stiff paper, glued upon it on the upper side. The veneer should be cut rather larger than the surface to be covered; if much twisted it may be damped and placed under a board and weight over night. This saves some trouble, but with veneers that are cheap it is not worth while taking much trouble about refractory pieces.

The wood to be veneered must now be sized with glue. The ordinary glue-pot will supply this by dipping the brush first into the glue, then into the boiling water in the outer vessel. This size must be allowed to dry before the veneer is laid on. We will suppose now that the veneering process is about to commence; the glue in good condition and boiling hot, the bench cleared, a basin of hot water with the veneering hammer and a sponge in it, a cloth or two, and everything in position that one will not interfere with, or be in the way of another.

First damp with hot water that side of the veneer which is not to be glued, then glue the other side. Secondly, go over as quickly as possible the wood itself, previously toothed and sized. Thirdly, bring the veneer rapidly to it with the outspread hands, and taking care that the edges of the veneer overlap a little all round. Fourthly, grasp the veneering hammer close to the pene (shaking off the hot water from it) and the handle pointing away from you. Wriggle it about, pressing the veneer down stoutly, and squeezing the glue from the middle out at the edges. If it is a large piece of stuff which is to be veneered, the assistance of a hot iron will be wanted to make the glue liquid again after it has set; but do not let it dry the wood underneath it, or it will burn the glue and scorch the veneer, ruining the work. Fifthly, having got out all the glue possible, search the surface for blisters, which will at once be betrayed by the sound they give when tapped with the handle of the hammer: the hot iron must be applied, or the inner vessel of the glue-pot itself, which often answers the purpose, and the process with the hammer repeated. When the hammer is not in the hand, it should be in the hot water. The whole may now be sponged over with hot water, and wiped as dry as can be. And observe, throughout the above process, never have any slop and wet about the work that you can avoid. Whenever you use the sponge, squeeze it well first. Damp and heat are wanted, not wet and heat. It is a good thing to have the sponge in the left hand nearly all the time, ready to take up any moisture or squeezed out glue from the front of the hammer.

So much for laying veneers with the hammer, which, though a valuable tool, is not much used in the best cabinet-makers' shops, cauls being adopted instead. Cauls are made of wood, the shape and size of the surface to be veneered, or better still, of rolled zinc plate, and being made very hot before a good blaze of shavings, they are clamped down on the

work when the veneer is got in its place. The cauls must previously be soaped, to prevent them sticking to the veneer. The whole is then left to dry together. The hammer is quite sufficient, however, in small cabinet shops, and for amateurs, who will not require to cover surfaces of any great extent. Veneers 5 feet long and 18 inches wide can be laid with the hammer, without assistance, and without leaving a blister. Cauls, however, are very necessary if a double-curved surface has to be veneered, or a concave surface; they need not be used for a simple convex surface. By well wetting one side of the veneer, it will curl up, and can be easily laid on such a surface; but it will be well to bind the whole round with some soft string, to assist in keeping it down while drying.

Our New Departure.

IN response to a very large number of requests, we have decided to greatly enlarge the YOUNG SCIENTIST. This change will take place with the issue for January 1883, and of course the price will at the same time be increased. We have fixed upon one dollar as the future yearly subscription to the YOUNG SCIENTIST, and from the many letters in our possession we feel sure that our new departure will give general satisfaction. The journal will be enlarged to nearly three times its present size, and of course the expense will be greatly increased, but this general advancement means to our readers something more than a mere change in size and price. It means greater variety and scope in the topics selected for discussion in the journal; it means greater thoroughness in working them out; it means more illustrations; it means greater regularity and promptness, and, finally, it means such an organization as will bring the YOUNG SCIENTIST close to every one of its seven thousand readers.

With the price at fifty cents, the manager of the YOUNG SCIENTIST was obliged to be editor, publisher, reporter, etc., etc., all rolled into one. With the higher price and more extended circulation, the YOUNG SCIENTIST will have a special editor with whose special duties no other calls shall be allowed to interfere, and in addition to this the staff of contributors and occasional writers will be largely increased. At the same time the former editor will lose none of his interest or influence; the YOUNG SCIENTIST will still be what it always has been, the representative of the Amateur Scientist and Mechanic. But with relief from the burden of minute detail comes greater opportunity to accomplish more important things, and maintain more thoroughly the more important departments.

With the January number, Mr. Fred. T. Hodgson, whose name is familiar to every reader of the YOUNG SCIENTIST, will join us in our editorial work. If you desire to see the results, just send on your subscription for 1883, or send by postal card a request for the January number.

BOOK NOTICES.

How to be Weather-Wise. A New View of Our Weather System. With Illustrations. By Isaac P. Noyes. 12mo., pp. 51, price 25 cents. Fowler & Wells, Publishers, 753 Broadway, New York.

The methods and operations of our weather bureau form one of the most wonderful results of modern science. If we take the state of practical meteorology at the time that Kæmitz wrote his work—barely half a century ago—and compare it with the results at present within the reach of scientific men, we shall obtain one of the most striking illustrations of the interdependence of the arts and sciences. No one of them grows without lifting all the others up with it. Our modern weather bureau is the outgrowth not only of an improved science of meteorology but of our extended system of telegraphy. Without the latter the former would be impossible. The work before us gives a very fair view of the working of this system, but we think the title is rather misleading. Any one who expects to learn from its pages how to forecast the weather will, we think, be disappointed. At the same time no one can read it carefully without gleaning much useful and interesting information.

Keely Outdone.

The following, which we clip from an exchange, beats Keely out of sight: "A Rochester gentleman proposes to furnish power to run the whole world, so to speak, but more particularly the ocean steamers and ships of all kinds, railroad trains, factories, etc. Like the other inventors, he proposes to get his power very cheap—in fact, for nothing. His idea is to construct a turbine wheel nearly one mile in diameter, with all the modern improvements. This wheel he intends to have placed in the great

maelstrom off the coast of Norway, attaching to it cables which shall span the oceans, and which, when the wheel once starts in motion, as it is, of course, sure to do in this wonderful current, will furnish power for everybody. All the expenses attached to this will be repairs to the wheel and the cables which may occur from time to time, 'And,' said the inventor to a reporter, 'you know that will amount to almost nothing.'"

Photographs that Wink.

The last new thing in photography surpasses the ingenuity of the man who invented the spirit photographs, and suggests how handy it would have been had that crafty person added this to his devices. A Frenchman takes one negative of a sitter with open eyes. Then he makes the sitter shut his eyes and remain in exactly the same position while another negative is taken. The two negatives are printed on the same paper, one on each side exactly coinciding. When this double-faced picture is held in proper position before a lamp, and the lamp is rapidly moved or caused to flicker, the curious effect is produced of long-continued winking. It is not claimed that a person looks more beautiful when he keeps winking, but it cannot be denied that it gives one a very interesting appearance.

Reversing the Wheels.

Experiments lately made at Blackburn with a train made up in imitation of that of the express which ran into the train standing in Blackburn station, to test the statement of the driver that he reversed his engine as soon as he found the brakes did not check his train, are of some interest, though they elicited the fact that the reversal of the engine of a train running at a high velocity has but a very small effect in reducing the speed. A high speed was attained, and the engine was reversed a quarter of a mile before reaching the station, but the train ran through the station at about 20 miles an hour, and had to be stopped by the brakes. Locomotive driving wheels, when running the reverse way, are not effective in stopping a train. The experiment shows how little can be gained by reversing an engine under such circumstances.

Practical Hints.

The Victoria Regia.—Mr. E. D. Sturtevant, a florist of Bordentown, N. J., has accomplished a feat hitherto unknown in the annals of floriculture in this country, that of growing to perfection in the open air a plant of the famous victoria regia, the giant water lily of South America. The plant now has leaves six feet in diameter, and has unfolded its first flower, which was the admiration of all beholders. Mr. Sturtevant's plant will continue to bloom for several weeks.

Rendering Tissues Waterproof.—Prepare the two following solutions: 2 lb. 8 oz. paraffine dissolved in 10 lb. tar-benzine, and 8 oz. caoutchouc dissolved in 5 lb. tar-benzine. The two solutions are well mixed together before using, and 8 oz. linseed oil varnish is added to the mixture. This mixture is spread cold on the tissue by means of a brush once on each side of the cloth.

Preservation of the Colors of Dried Plants.—According to M. Storbzl, the slow immersion of the fresh plant in a boiling solution of one part of salicylic acid in 600 parts of alcohol, and then shaking off superfluous moisture, previous to pressing in the usual way between blotting-paper, will more nearly preserve the natural color than any other method.

Metrical Abbreviations.—The following abbreviations for metrical units have recently been decreed by the Spanish Government for Spain and its colonies:

Kilometer	km.	Cubic decimeter	dm^3.
Meter	m.	Cubic centimeter	cm^3.
Decimeter	dm.	Cubic millimeter	mm^3.
Centimeter	cm.	Hectoliter	hl.
Millimeter	mm.	Decaliter	dal.
1-1000 millimeter, or micro-millimeter	mmm.	Liter	l.
Square kilometer	km^2.	Deciliter	dl.
Hectare	ha.	Centiliter	cl.
Are	a.	Ton	t.
Square meter	m^2.	Metrical cwt	q.
Square decimeter	dm^2.	Kilogram	kg.
Square centimeter	cm^2.	Gramme	g.
Square millimeter	mm^2.	Decigramme	dg.
Stere	S.	Centigramme	cg.
Cubic meter	m^3.	Milligramme	mg.

Silvering Iron.—A manufacturer in Vienna employs the following process for silvering iron: He first covers the iron with mercury, and silvers by the galvanic process. By heating to 300° C., the mercury evaporates and the silver layer is fixed. Ironware is first heated with diluted hydrochloric acid, and then dipped in a solution of nitrate of mercury, being, at the same time, in communication with the zinc pole of an electric battery, a piece of gas carbon or platinum being used as an anode for the other pole. The metal is soon covered with a layer of quicksilver; is then taken out and well washed and silvered in a silver solution. To save silver the ware can be first covered with a thin layer of tin; one part of cream of tartar is dissolved in eight parts of boiling water, and one or more tin anodes are joined with the carbon pole of a Bunsen element. The zinc pole communicates with a well-cleaned piece of copper, and the battery is made to act till enough tin has deposited on the copper, when this is taken out and the ironware put in its place. The ware thus covered with tin, chemically pure and silvered, is much cheaper than any other silvered metals.

EXCHANGES.

Only those who are *yearly* subscribers, and whose names are entered on our books have the privilege of inserting exchanges.

Exchanges must be on separate slips of paper or postal cards. If mixed with business matter in letters or cards they are filed away and never reach the printer.

Exchanges must not exceed thirty words.

Buying and selling belong to the advertising department.

We reserve the right to omit the exchange column, wher we have not room for it, and the amount of space at our disposal will regulate the number of insertions given to each *exchange*, the preference being always given to those who have not previously used our columns.

I have a large assortment of foreign stamps to exchange, also Confederate money. Collectors send sheet and I will return it with mine. Box No. 2, Coeymans, N. Y.

Electric bell engine, cost $15; pair of analytical scales, cost $10; pair of Bell Telephones to exchange for a printing press, watch or offers. Geo. N. Bigelow, Box 754, Palmyra, N. Y.

To exchange for offers first four (fifth when completed) bound volumes of YOUNG SCIENTIST. J. N. Brooks, P.O. 1468, N. Y. City.

Any person wishing to trade bird's eggs may apply to me and I will send them my list of bird's eggs. I have only a few at present, but am receiving a number every month. A. G. G., Box 26, Summit, New Jersey.

Minerals of Idaho for Standard Works on the Horse—Wallace's Registers and turf journals. Wanted, also other useful books, bound and in good condition. Many varieties named in my list. J. P. Clough, Junction Lemhi Co., Idaho.

Wanted engraver's tools with book of instructions, for a Victor Press, with cabinet, 2 type cases, type, ink roller and furniture complete; perfectly new. L. Warren, 72 Cumberland St., Brooklyn, N. Y.

A Fletcher Foot-Blower, cost $5, as good as new; will exchange for a Cushman, 2 in. or up scroll chuck, or other make; will give a satisfactory trade on the difference in price, if any. Louis Lutz, St. Clair Street, Toledo, O.

I have a lot of "Galaxy" (magazines) which I would like to exchange for an air rifle in good condition, a collection of birds' eggs, or offers. W. B. Greenleaf, 480 La Salle Ave., Chicago, Ill.

I have a Mechanical Telegraph with book of instructions, books, etc., which I wish to exchange for good microscopical objects, mounted on 3 x 1 slips. Address, with list, J. H. Frey, Millersburg, Ohio.

To exchange, "How to Use Microscope," Wells' "Natural Philosophy," and many other books, chemical apparatus, etc , for good photographic camera, and lenses. W. H. Weed, 254 Putnam Ave., Brooklyn, N. Y.

Wanted "Quimby's New Bee Keeping," for "Our Own Birds of the United States," by W. S. Baily; new. Joseph Anthony, Jr., Colota, Whiteside Co., Ill.

Wanted a good book in anatomy, in exchange for a book on chemistry, or for story books. A. G. G., Box 26, Summit, New Jersey.

A German-silver trimmed, patent lined, cocoa flute, cost $4, in good order, for good spy-glass, photo-material, or offers. Ewing McLean, Greencastle, Ind.

I have some fossil shells from the west bank of the Mississippi, to exchange for Indian relics. A. W. S., 187 E. 71st St., N. Y.

I have a magic lantern, Ruby pattern, nearly new, and 5 views; also "Our First Century," bound in leather, cost $7; state what is wanted in exchange. I. N. Spencer, Box. 217, So. Manchester, Conn.

First-class telegraph instrument and attachments, and "Wood's Botany," for bound volumes of periodicals, books, or offers. H. P. Albert, Anderson, Iowa.

Wanted a book on treatment and care of canary, also breeding of same; will give in exchange book named "Market Garden, Flower Garden and Bees," or 40 "Scientific Americans" or "Seaside Libraries;" want also old books. M. J. Mulvihill, Norwalk, Conn.

Coins, minerals, stamps, books, type, fishing tackle (very complete) and fish pole, bronze inkstand, etc., for coins, medals, stamps, war envelopes, old newspapers, and Continental, Colonial and Confederate currency. F. F. Fletcher, 103 Main St., St. Johnsburg, Vt.

Blow-pipe set (cost $10), large illustrated family Bible (cost $7.50), for Wood's Botany, Dana's Geology, or printing press and type. H. W. Noble, Box 134, South Dansville, N. Y.

Wanted, offers for fossil shells from the west coast of Africa. A. W. Seward, 187 E. 71st St.

I have a number of birds' eggs I should like to trade for other birds' eggs; send for list of trading eggs. A. G. G., Box 26, Summit, New Jersey.

For a microscope stand or offers, a 36-inch turning lathe (new) and a number of scientific books; send for list. A. Kendall, Somerville, Mass.

Wanted services of amateur printer with small office (or large), in exchange for an interest in a well-established weekly paper, good size. Eagle Office, Plymouth, N. H.

American Agriculturist microscope, new, cost $15, for amateur photographic apparatus, lever watch, 22 calibre breech-loading sporting rifle or magic lantern of equal value. Wm. A. Walker, Rockland, R. I.

I. T. Bell, Franklin, Pa., has back numbers of Scientific American, Forest and Stream, and Young Scientist, good flute, chessmen, books, etc., for good magic lantern, revolver, scarce coins, or offers.

A steel spring bracket-saw, 2 doz. saw blades, and about 1 doz. patterns for a good stylographic pen or offers; send postal before exchanging. Geo. Oakley, Rutherford, N. J.

A rosewood banjo, 11 inch head, 12 nuts, fully strung, together with lot of dime banjo music and instructions, for microscope, Webster's Unabridged, monkey, squirrel and cage, or offers. J. DeWitt Clark, P. O. Box 37, Brooklyn, N. Y.

For self-inking printing press and type, one Henry rifle, 16 shot, 44 cal., cost $40, in good order, or one double barrel shot gun, barrels London fine twist, or offers. J. B. Garrison, Belton, Bell Co., Texas.

What offers for "The Chefs D'Oeuvre D'Art, Paris Exhibition 1878," cost $16, good as new, bound; 1 large photo camera, complete, cost $95; Scientific American from 1859 to 1880, 4 vols. bound. D. Keesler, Stony Point, N. Y.

Sea shells of Atlantic coast, scientifically marked, for books, old or new magazines, Indian relics, natural history specimens, apparatus; anything. Wilfred Leon Miller, P. O. Box 392, Cape May, N. J.

A new 40 diameter microscope, corals, and minerals, for a stylographic pen, air gun, or offers. J. McBride, 54 Garley St., Chicago.

A dulcimer that cost $20, books and fossils, for a telescope, microscope, fossils, Indian relics, or offers. E. J. Votaw, Salem, Iowa.

A self-inking model press, 5 x 7½, cost $23; $90 worth of scroll-saw designs in lots to suit; Scientific American, 1880; Palliser's Useful Details, $3; for photo outfit or offers. C. H. Parker, Coldbrook Springs, Mass.

Telegraph key and sounder, Frank Leslie's Illustrated Magazines, mounted microscopic objects, natural curiosities, for bull's-eye condenser, photograph camera, Unabridged Webster Dictionary, or offers. W. T. Alan, Greenville, Mercer Co., Pa.

Large magic lantern, spectroscope, pantagraph, for enlarging drawings, rosewood writing desk, man's saddle, for microscope, photo outfit or offers. Thomas Walters, Bergen St., East of Brooklyn Ave., Brooklyn, N. Y.

Model card press, chase 3¼ x 5¼, with 4 fonts type, cases, etc., for good foot lathe. Mills Day, 2 Farmington Av., Hartford, Ct.

French microscope, inclines to any angle, delicate fine motion, neat upright case, cost $17.50, for scientific books; send list to W. Fitz, P.O. Box 2852, New York.

Wanted, Quinby's New Bee Keeping, for Our Own Birds of the United States, by W. S. Baily; new. Joseph Anthony, Jr., Coleta, Whiteside Co., Illinois.

One years' copy of Aldine, cost $5.50, and German accordion, with instructions how to use it, cost $5.00, for offers. Chas. Dempwolf, 86 Benson St., Paterson, N. J.

THE Young Scientist

SCIENCE IS KNOWLEDGE.

KNOWLEDGE IS POWER.

A PRACTICAL JOURNAL OF

HOME ARTS.

VOL. V. NEW YORK, DECEMBER, 1882. No. 12.

Some Notes on Bird Stuffing.

OUR younger readers are advised not to attempt bird stuffing unless some person is near them who has had some experience in the matter. Care must be taken, while using the knife, to avoid being cut. Be very careful while using the corrosive sublimate, and when the work is completed, wash your hands well with castile soap and soft water.

This method of stuffing will be found to give good satisfaction if strictly followed:

Note 1st.—In dissecting, three things only are necessary to ensure success; viz., a penknife, a hand not coarse and clumsy, and practice. In stuffing you require cotton, a needle and thread, a little stick, glass eyes, a solution of corrosive sublimate, and any kind of temporary box to hold the specimens. Wire is worse than useless, as it gives a stiff appearance to the object stuffed.

Note 2nd.—A very small proportion of the skull bone, say from the fore part of the eye to the bill, is to be left in, part of the wing bones, the jaw bones, and half of the thigh bones remain. Everything else, flesh, fat, eyes, bones, brain and tendons, are all to be taken away.

Note 3rd.—In taking off the skin from the body it will be well to keep in mind that you must try to shove in lieu of pulling it, lest you stretch it. Throughout the whole operation, as fast as you detach the skin from the body, you must put cotton immediately betwixt the body and it; this will prevent the plumage getting dirty.

Note 4th.—Let us now proceed to dissect a bird. Have close by you a little bottle of corrosive sublimate, also a little stick and a handful or two of cotton. Now fill the mouth and nostrils with cotton, and place it on your knee on its back, with its head pointed to your left shoulder. Take hold of the knife with your two first fingers and thumb, the edge upward; you must not keep the point of the knife perpendicular to the

body of the bird, because, were you to hold it so, you would cut the inner skin, and thus let the intestines out. To avoid this let your knife be parallel to the body, and then you can divide the outer skin with great ease.

Note 5th.—Begin on the bird below the breast bone and cut down the middle, quite to the vent. This done, put the bird in any convenient position, and separate the skin from the body, till you get at the middle joint of the thigh. Cut it through, and do nothing more there at present except introduce cotton all the way on that side, from the vent to the breast bone. Do exactly the same on the opposite side.

Note 6th.—Now place the bird perpendicular, its breast resting on your knee, with its back towards you. Separate the skin from the body on each side of the vent, and never mind at present the part at the vent to the root of the tail. Bend the tail gently down to the back, and while your finger and thumb are keeping down the detached parts of the skin on each side of the vent, cut quite across and deep, until you see the back bone near the oil gland at the root of the tail. Sever the back-bone at the joint and then you have all the root of the tail, together with the oil gland, dissected from the body. Apply plenty of cotton.

Note 7th.—After this, by shoving and cutting get the skin pushed up until you come to where the wing joints join the body. Apply cotton, and then cut this joint through, and do the same at the other wing; add cotton, and gently push the skin over the head, cut out the roots of the ears, and continue skinning till you reach the middle of the eye; cut the membrane quite through, otherwise you would tear the orbit of the eye.

Note 8th.—After this nothing difficult intervenes to prevent your arriving at the root of the bill; when this is effected cut away the body, leaving just a little bit of the skull; clean well the jaw bones, and touch the skull and corresponding parts with the solution. Now all that remains to be removed is the flesh on the middle joints of the wings, one bone of the thighs, and the fleshy root of the tail.

Note 9th.—Now fasten thread to the joints of each wing, and then tie them together, leaving exactly the same space betwixt them as your knowledge in anatomy informs you existed there when the bird was entire; hold the skin open with your finger and thumb, and apply the solution to every part of the inside. Neglect the head and neck at present, they will receive it afterwards.

Note 10th.—Now fill the body moderately with wool to prevent the feathers below the breast from being injured. You must recollect that half of the thigh, or in other words one joint of the thigh bone, has been cut away. Now, as this bone never moved perpendicular to the body, but on the contrary in an oblique direction, of course as soon as it is cut off the remaining part of the thigh and leg, having nothing now to support them obliquely, must naturally fall to their perpendicular. Hence the reason why the legs appear considerably too long. To correct this take your needle and thread, fasten the ends round the bone inside, then push the skin just opposite to it, and then tack up the thigh under the wings with several strong stitches. This will shorten the thigh, and render it quite capable of supporting the body without the aid of wire.

Note 11th.—Now is the time to put in the cotton for an artificial body, by means of the little stick, and then sew up the orifice you originally made, beginning at the vent. Lastly, dip your stick into the solution, and put it down the throat three or four times, in order that every part may receive it. When the head and neck are filled with cotton quite to your liking, close the bill, as in nature. Bring the feet together by a pin, and then run a thread through the knees, by which you may draw them to each other, as near as you may judge proper. Nothing now remains to be added but the eyes; adjust the orbit to them as in nature, and that requires no other fastener. After this, touch the bill, orbit, feet, and former oil gland at the root of the tail, with the solution, and then you have given to the bird everything necessary, except attitude and a proper degree of elasticity.

Note 12th.—Procure any common ordinary box, fill one end of it, about three-fourths up to the top, with cotton, forming a sloping plane. Make a moderate hollow to receive it, and place the bird in its right position. If you wish to elevate the wings do so, and support them with cotton. If you wish to have the tail expanded, reverse the order of the feathers, beginning from the two middle ones, and when dry place them in their true order, and the tail will preserve for ever the expansion you have given it. In three or four days the feet lose their natural elasticity, and the knees begin to stiffen. When you observe this, it is the time to give the legs any angle you wish, and to arrange the toes. When the bird is quite dry, pull the thread out of the knees, and take away the needle, and all is done.

Flying Machines.

TO be able to fly like a bird has always been an object of great desire to most men, and to-day there are hundreds of inventors, old and young, who are wasting their time and energies on flying machines. The visitors to the late fair of the American Institue might have seen a flying machine for which the inventor made the most extravagant claims, and yet to any person at all familiar with sound mechanical principles it was obvious that this machine never could be of the slightest utility.

There are two problems involved in the flying machine, and inventors are very apt to get confused in regard to them. First of all we have to provide means for supporting the machine in the air; and secondly, it is necessary to have some way of propelling the machine without regard to the direction of the aerial currents—that is to say, of the wind. Before the days of balloons, machines had been made to support themselves in the air by their own motion. The flying pigeon made by Archytas was a striking example of this, and in more modern times we have many instances where heavy bodies are supported by the resistance presented by the air to their motion. One of the most familiar of these is the "artificial pigeon" used by sportsmen. This consists of a piece of sheet iron formed into the shape of the screw of a steam vessel. It is placed on a spindle around which a cord is wound, and when this cord is rapidly drawn off the spindle and screw revolve with great speed, just as a humming top revolves when the cord is drawn off. The screw then rises to a great height in the air, and sometimes flies to a distance of sixty to one hundred yards. Our young friends who wish to try this experiment can easily make the apparatus out of a common spool and a piece of card. The card is cut to the form of a propeller screw and twisted in the same way. Two pins are driven into the end of the spool about an eighth of an inch from the hole and on opposite sides, and holes are made in the card so that it may be slipped on these pins and held fast while the string is being drawn off the spool. As soon as the string leaves the spool, however, the card becomes loose and flies off to a considerable distance.

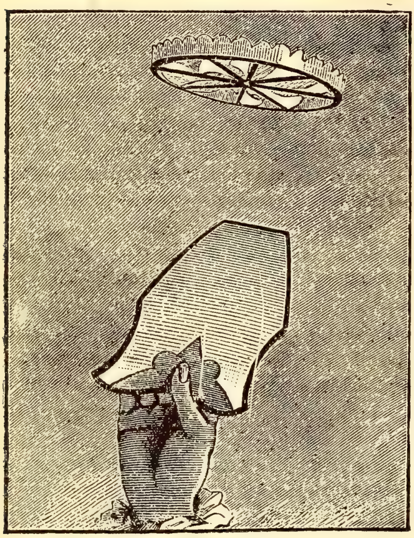
Another mode of showing the mechanical action of the air is as follows: Make a wheel with rim and spokes out of cardboard as shown in the figure. The card must be cut away so as to leave but very narrow spokes so that the air may have plenty of room to pass through. To each spoke is pasted a piece of stiff writing paper cut to the shape of a long triangle. The paper is then bent upwards so as to present a slanting face to the current.

When such a wheel is thrown into the air and fanned from beneath as shown in the figure, it will first be supported by the current from the fan, but as soon as this has produced a sufficiently rapid rotation the wheel will continue to mount of itself until it stops spinning. Such a wheel might be made to revolve by means of a spool fixed as we have just described, and then it would rise without any fan.

And older and more common than all these are the wings of birds, which show that weights of many pounds may be raised and transported through the air by mechanical means alone.

Thus far, however, all attempts to raise and propel a weight as great as that of an ordinary man by mechanical means have

failed, and neither the strength of human muscles, the power of steam or the force of more subtle agents, like electricity, have been found equal to the demand. But as soon as the balloon was invented it was seen at once that here was a means of supporting any required weight with



FLYING WHEEL.

safety and certainty, and the most extravagant hopes were entertained in regard to its ultimate success. It was seen at once, however, that this success was delusive, and that no balloon could ever be made a useful means of transport between any two given points, simply because its great bulk and the entire absence of any means of guiding it, left it at the mercy of the winds. The conditions under which a ship can be sailed within one or two points of the wind's eye are very different from those which obtain in the case of the balloon. In the case of the ship, while the sails are acted on by the wind, the hull, and especially the rudder, are immersed in a heavy liquid whose great resistance makes it easy to guide the ship. In the case of the balloon we have nothing of the kind; it is impossible to use a rudder with a balloon—attempts have therefore been made to steer the balloon by means of mechanical propellers, but without success. There has always been too much balloon and too little propeller.

Any one who will carefully study the subject in the light of sound mechanical principles will see that the only thing necessary to insure success for the flying machine is the invention of a motor of vastly greater power in proportion to its weight than anything we now have. As soon as this is invented flying will become a comparatively easy matter. But until that has been done, flying machines are an impossibility—just as locomotives and steamboats were an impossibility so long as the only steam engines were the ponderous affairs of Papin and Newcomen.

We have dwelt upon this subject because we know that it has a peculiar fascination for young minds, and many of our readers may devote themselves to the invention of a flying machine. We hope that before spending time and money on the subject they will carefully study the points we have discussed. In any case, from such study nothing but good can come.

Solomon and the Blacksmith.

THERE is a legend told of the wise king Solomon, which was recently republished in the *Blacksmith and Wheelwright*, that is interesting and instructive, and from which a moral may be drawn, as it shows how dependent the arts are on one another. We do not exactly agree with the idea intended to be conveyed by the story that the blacksmith is the "all-important," for it requires other arts than his to prepare the materials and appliances to work with; nevertheless, the story has a moral which our readers will easily discover:—

Among all mechanics the blacksmith undoubtedly has reason to be proud of his position, and in the recognition which history says he received at the hands of the wise king, there is applied the recognition which in one way or another, although seldom expressed, he received at the hands of modern mechanics. There is no trade or handicraft that is independent of the blacksmith, which fact lends additional interest to the following legend:

"1. And it came to pass, when Solomon, the son of David, had finished the Temple at Jerusalem, that he prepared a feast for his chief craftsmen and artificers, and spread the tables with the fatness of the land, and with the wine and corn and oil thereof.

2. And the seat of the king was apart on a raised dais, facing the head of the table, and the two famous pillars of bronze, with their beautiful capitals of lilies, pomegranates and delicate network, stood, one on his right hand and the other on his left, and the lintel thereof was a canopy over the head of the king.

3. And Solomon had also prepared a seat of honor, and set it on his right hand, ready for that craftsman who might be pronounced most worthy among all who wrought in building the house of the Lord.

4. And when all was ready he called unto him his chief architects and master-overseers, and the head artificers who were cunning workers in gold and silver, in bronze and ivory, and in wood and stone, yea, all who had labored in building the temple of the Most High, and he said unto them:

5. 'Come now with me and partake of the feast which I have prepared. Stretch forth your hands; eat, drink, and be merry. The skilled artificer is worthy of honor. Is not the laborer worthy of his hire? Muzzle not the ox that treadeth out the corn upon the threshing-floor.'

6. And when Solomon and his guests had arrived at the place of the feast, they beheld a man, clad in the garb and covered with the soil of labor, seated in the chair of honor not yet awarded. And the king waxed wroth, and said, 'What manner of man art thou? Why comest thou thus unseemly and unbidden to our feast, where none are invited save the chief workers on the temple?'

And the man answered and said, 'Please you, I came not unbidden. Was it not proclaimed that this day the chief workmen of the temple dine with the king? Therefore am I come.'

And when the man had thus spoken, the guests talked with each other, and he who carved the cherubim spake aloud and said: 'This fellow is no sculptor. I know him not.'

And he who inlaid the roof with pure gold said: 'Neither is he of those who work in refined metals.' And he who wrought in raising the walls said: 'He belongs not with those who are cutters of stone.'

And one who labored in shaping the timbers for the roof said: 'We, who are cunning in cedar wood, and know the mystery of joining strange timbers together, know him not; he is not of us.'

Then said King Solomon: 'How sayest thou now? Wherefore should I not have thee plucked by the beard, scourged with a scourge, and stoned with stones, even unto death?'

But the man was nowise daunted, and he rose from the seat, and came to where the wine was set, and took a cup of the wine and raised it high and spake aloud, saying, 'Oh, king! live forever!' He then drank long until the cup was emptied.

He now returned to the seat and spake to the guests who had rebuked him, and said unto the chief of the carvers in stone: 'Who made the instruments with which you carve?'

And he answered: 'The blacksmith.'

And to the chief of the workers in wood he said: 'Who made the tools with which you felled the cedars of Lebanon, and shaped them into pillars and roof for the temple?'

And he also answered: 'The blacksmith.'

Then he spake unto the artificer in gold and ivory and precious stones, saying: 'Who fashioned the instruments with which you wrought beautiful ornaments for my lord the king?'

And he, too, made answer the same: 'The blacksmith.'

Then said the man to Solomon: 'Behold, oh king! I am he whom, when men deride, they call blacksmith; but when they would honor me they call me Son of the Forge. These craftsmen say truly that I am not of them; I am their superior. Without *my* labor first, *their* labor could not be. The great Tubal Cain, whom all men honor, taught those who in turn taught me my handicraft, and the great

Vulcan, who wrought in fire and smoke and sweat, as I do, was it not deemed fitting that he should have even the Queen of Beauty to wife?'

'Son of the Forge,' said Solomon, 'I too honor thee, thou worthy successor of the great master, Tubal Cain. Take thou this seat at my right hand' prepared for the *most* worthy; it is thy due.'

Thus it came to pass at the feast of Solomon, the wise king of Israel, and from that time forth the smiths were held in high esteem, and greatly increased and multiplied in all lands."

Something About Scroll-Sawing.

WHEREVER there is a boy or girl in a house, the head of that house should provide for their use a serviceable scroll-saw. Indeed, the scroll-saw has become a necessity to every household; as much so, almost, as the family sewing machine, for of late years fret-sawing has become quite popular, and no boy of fourteen years of age is considered "up to the times" if he is not more or less expert in this fascinating art. This is quite natural; for the work is instructive, interesting and profitable, and but little practice is required to produce many ornamental, useful and really artistic articles for the decoration of the parlor and dining-room, such as brackets. screens, book shelves and racks, wall pockets, vases, easels, photograph frames, fancy boxes, clocks, inlaid panels, mottos and dozens of other things. The work, too, awakens an interest in drawing and designing, cultivates a love of art, and is therefore especially instructive to young people. It is also a source of amusement, and affords to young and old great delight as a pastime. It may also be made profitable, as many of the beautiful articles that can be made can readily be disposed of, or can be made for holiday and birthday gifts, and will be more valued by the recipients than articles for which a high price would have to be paid, thus saving to the giver a respectable sum. There is a pleasure, also, connected with this kind of work that is almost indescribable.

The work grows, as it were, under the hand of the operator. Church, bazaar, boudoir, parlor, or lodge-room, all may be beautified and made more attractive by this beautiful art. There is no scarcity of designs or patterns, even if the operator is not equal to do his own designing, as a superficial glance at any of the catalogues of patterns now offered by any of the dealers in amateur goods will show.

Fig 1.

Fig. 2.

The accompanying engravings are taken from Chas. E. Little's designs, and are neat, simple and effective. Fig. 1, "Welcome," is designed for a motto.

This looks very neat if cut from white holly, less than an eighth of an inch thick, and placed on a background of dark terra-cotta velvet, or fine cloth. When placed on a black background the contrast is too striking.

Fig. 2 shows another motto—one that is appropriate at this time of the year. The letters may be cut from thin mahogany or dark cherry, and nicely glued on light

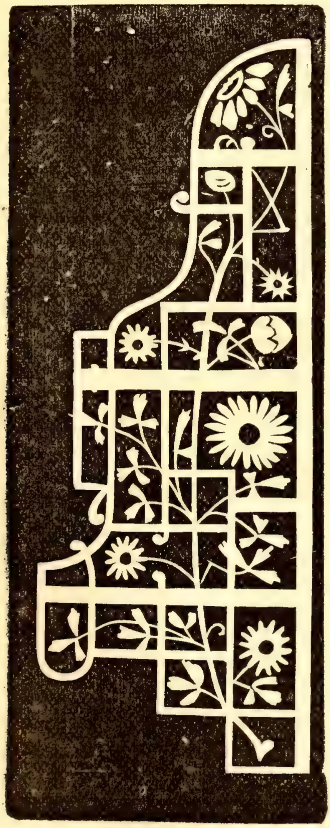


Fig. 3.

cream-colored cashmere or flannel; and when nicely framed, with glass complete, and surrounded with a wreath of ivy or other similar evergreen, looks exceedingly chaste and beautiful. Of course the woods and backgrounds may be varied to suit the taste and conditions, but we advise, in all cases, to avoid very strong contrasts.

The design shown at Fig. 3 is very neat, and one that can be manipulated easily. It makes a side for either an ordinary open wall cabinet, or for a common bracket with three shelves.

We should prefer cutting this design from walnut or mahogany, not less than one quarter of an inch thick. Care must be taken in following the straight lines, as the beginner will find more difficulty in making good work on straight lines than on curved ones.

Our New Departure.

IN response to a very large number of requests, we have decided to greatly enlarge the YOUNG SCIENTIST. This change will take place with the issue for January 1883, and of course the price will at the same time be increased. We have fixed upon one dollar as the future yearly subscription to the YOUNG SCIENTIST, and from the many letters in our possession we feel sure that our new departure will give general satisfaction. The journal will be enlarged to nearly three times its present size, and of course the expense will be greatly increased, but this general advancement means to our readers something more than a mere change in size and price. It means greater variety and scope in the topics selected for discussion in the journal; it means greater thoroughness in working them out; it means more illustrations; it means greater regularity and promptness, and, finally, it means such an organization as will bring the YOUNG SCIENTIST close to every one of its seven thousand readers.

With the price at fifty cents, the manager of the YOUNG SCIENTIST was obliged to be editor, publisher, reporter, etc., etc., all rolled into one. With the higher price and more extended circulation, the YOUNG SCIENTIST will have a special editor with whose special duties no other calls shall be allowed to interfere, and in addition to this the staff of contributors and occasional writers will be largely increased. At the same time the former editor will

lose none of his interest or influence; the YOUNG SCIENTIST will still be what it always has been, the representative of the Amateur Scientist and Mechanic. But with relief from the burden of minute detail comes greater opportunity to accomplish more important things, and maintain more thoroughly the more important departments.

With the January number, Mr. Fred. T. Hodgson, whose name is familiar to every reader of the YOUNG SCIENTIST, will join us in our editorial work. If you desire to see the results, just send on your subscription for 1883, or send by postal card a request for the January number.

Practical Hints.

To Bend a Pipe.—Fill it with melted resin. When the resin hardens bend the pipe, and it will retain its round form. Remove the resin by heating.

Lighting Fires.—Many housekeepers have at some time realized the difficulty of lighting a grate fire in a still, damp morning, when the chimney will not draw, and vigorous blowing proves ineffectual. Science explains the trouble as "caused by the difficulty encountered in overcoming the inertia of the long column of air in the pipe or chimney by the small column of air that can be forced up through the interstices of wood and coal, at the bottom of which the fire is kindled." This may be remedied by first lighting a few bits of shaving or paper placed upon the top; thus, by the heated air's forcing itself into the chimney and establishing there an upward current, the room is kept free from the gas or smoke which is so apt to fill it, and the fire can then be lighted from below with good success.

Blacking Brass.—A correspondent of the *English Mechanic* says: I have tried all the various recipes recommended—nitrate of silver, platinum bichloride, etc.—but never found any work so satisfactorily and cheaply done as by the reduction of nitrate of copper to the oxide. I find the best way of using is to apply the solution to the brass to be blacked with a camel-hair brush, previously slightly heating the metal; then to raise the heat until the requisite color is produced; finishing by rubbing with a soft rag, and either oiling or lacquering. I can confidently recommend this as the very best method of producing that good black seen in first-class optical goods, observing that the process will not do for soft-soldered articles, as the heat necessary to produce the black is greater than the melting point of soft solder.

EXCHANGES.

Only those who are *yearly* subscribers, and whose names are entered on our books have the privilege of inserting exchanges.

Exchanges must be on separate slips of paper or postal cards. If mixed with business matter in letters or cards they are filed away and never reach the printer.

Exchanges must not exceed thirty words.

Buying and selling belong to the advertising department.

We reserve the right to omit the exchange column, when we have not room for it, and the amount of space at our disposal will regulate the number of insertions given to each *exchange*, the preference being always given to those who have not previously used our columns.

I have a large assortment of foreign stamps to exchange, also Confederate money. Collectors send sheet and I will return it with mine. Box No. 2, Coeymans, N. Y.

Electric bell engine, cost $15; pair of analytical scales, cost $10; pair of Bell Telephones to exchange for a printing press, watch or offers. Geo. N. Bigelow, Box 754, Palmyra, N. Y.

To exchange for offers first four (fifth when completed) bound volumes of YOUNG SCIENTIST. J. N. Brooks, P.O. 1468, N. Y. City.

Any person wishing to trade bird's eggs may apply to me and I will send them my list of bird's eggs. I have only a few at present, but am receiving a number every month. A. G. G., Box 26, Summit, New Jersey.

Minerals of Idaho for Standard Works on the Horse—Wallace's Registers and turf journals. Wanted, also other useful books, bound and in good condition. Many varieties named in my list. J. P. Clough, Junction Lemhi Co., Idaho.

Wanted engraver's tools with book of instructions, for a Victor Press, with cabinet, 2 type cases, type, ink roller and furniture complete; perfectly new. L. Warren, 72 Cumberland St., Brooklyn, N. Y.

A Fletcher Foot-Blower, cost $5, as good as new; will exchange for a Cushman, 2 in. or up scroll chuck, or other make; will give a satisfactory trade on the difference in price, if any. Louis Lutz, St. Clair Street, Toledo, O.

I have a lot of "Galaxy" (magazines) which I would like to exchange for an air rifle in good condition, a collection of birds' eggs, or offers. W. B. Greenleaf, 480 La Salle Ave., Chicago, Ill.

I have a Mechanical Telegraph with book of instructions, books, etc., which I wish to exchange for good microscopical objects, mounted on 3 x 1 slips. Address, with list, J. H. Frey, Millersburg, Ohio.

To exchange, "How to Use Microscope," Wells' "Natural Philosophy," and many other books, chemical apparatus, etc., for good photographic camera, and lenses. W. H. Weed, 254 Putnam Ave., Brooklyn, N. Y.

Wanted "Quimby's New Bee Keeping," for "Our Own Birds of the United States," by W. S. Baily; new. Joseph Anthony, Jr., Colota, Whiteside Co., Ill.

Wanted a good book in anatomy, in exchange for a book on chemistry, or for story books. A. G. G., Box 26, Summit, New Jersey.

A German-silver trimmed, patent lined, cocoa flute, cost $4, in good order, for good spy-glass, photo-material, or offers. Ewing McLean, Greencastle, Ind.

I have some fossil shells from the west bank of the Mississippi, to exchange for Indian relics. A. W. S., 187 E. 71st St., N. Y.

I have a magic lantern, Ruby pattern, nearly new, and 5 views; also "Our First Century," bound in leather, cost $7; state what is wanted in exchange. I. N. Spencer, Box. 217, So. Manchester, Conn.

First-class telegraph instrument and attachments, and "Wood's Botany," for bound volumes of periodicals, books, or offers. H. P. Albert, Anderson, Iowa.

Wanted a book on treatment and care of canary, also breeding of same; will give in exchange book named "Market Garden, Flower Garden and Bees," or "Scientific Americans" or "Seaside Libraries;" we also old books. M. J. Mulvihill, Norwalk, Conn.

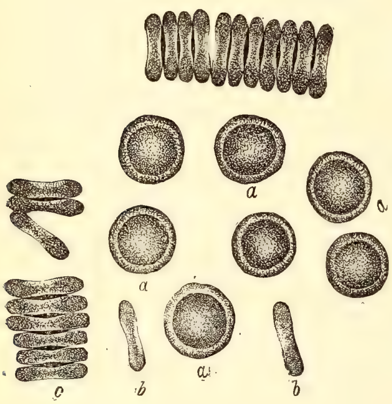
Blood Under the Microscope.

OF all the strange things revealed by the microscope, none are more wonderful than those which have been discovered in connection with blood. To ordinary vision the bloods of different animals appear nearly alike. They appear as a red liquid, differing somewhat in color, etc., under varying conditions, but substantially the same under all. Other red liquids, such as the red juice of fruit, red paint, etc., have often been mistaken for blood, and in some cases it would be almost impossible to prove that they were not blood without the aid of the microscope. There are various animal fluids, which, if properly colored by vegetable colors, might deceive even experts; but when placed under an ordinary ten dollar microscope they at once reveal their true characters, and show an entire absence of those peculiar elements which are always found in blood.

If we take a speck of blood, such as we may obtain by pricking the finger with a pin, or causing some scratch to bleed afresh, and after placing it on a glass slide, spread it out very thinly by drawing another piece of glass or a knife blade across it, we shall obtain the appearance presented in the figure on the next page, when we place the slide under a microscope with a magnifying power of one to three hundred diameters. Here we see some of the corpuscles lying flat, so as to show their round, disc-like sides, as at *a*, *a*, *a*, while others are turned up edgewise and look like *b*, *b*. Sometimes the corpuscles cling together like rolls of coin or *rouleaux*, as they are called, and then they appear as shown at *c*, *c*. There are more corpuscles shown in rouleaux in the engraving than usually occur when a drop of blood is taken from a person in good health, but the form and appearance of the corpuscles are very well shown, and they are the elements which

give to blood its chief peculiarities under the microscope.

These characteristic specks have been called globules, discs, corpuscles and other names, but the term "corpuscle" is the one now generally adopted, as it conveys no statement as to the form of the object. The most curious thing about these corpuscles is that they differ greatly in size and shape in different animals, but are always nearly alike in different individuals of the same species. Thus the blood of all human beings is nearly the same; so is that of all horses, sheep, dogs, fish, frogs, etc., though the corpuscles of horses, fish and frogs differ greatly from



HUMAN BLOOD CORPUSCLES.

each other. In the plate forming our frontispiece we have collected a few of the most marked of these. First of all, the reader will observe that they differ in shape, the round corpuscles of No. 3, presenting a marked contrast to the oval ones shown in 4, 5, 6, 8, 10. As a general rule, the blood of animals which suckle their young (*mammalia*) are round, an example of this being the human blood shown at 3. On the other hand, corpuscles from the blood of birds, fishes and reptiles are generally oval, as may easily be proved by the blood of a chicken or frog—two very easily procured animals. To this rule, however, there are some marked exceptions. Thus the blood corpuscles of the camel, shown at 4, are elliptical, and the blood corpuscles of the loach—a little fish that is found in European waters—is round.

The size too of the corpuscles varies greatly. Thus the blood of the proteus, No. 10, shows gigantic corpuscles nearly 1-400th of an inch long, while the blood corpuscles of the musk deer are so small that it would take twelve thousand of them, laid side by side, to extend across one inch, and we have in our western waters an animal, the *amphiuma*, with corpuscles even larger than those of the proteus. Both the proteus and the amphiuma are allied to the frogs, but are hideous looking objects.

Our readers will now easily understand how it is that microscopists can not only distinguish blood from most other liquids, but can distinguish the bloods of different animals from each other. Thus there would be no difficulty in distinguishing between the blood of the frog (No. 6) and that of a man (No. 3), and cases have arisen where this power on the part of microscopists has carried consternation to those who were not aware of it. Thus it is related that on one occasion a woman presented herself as an out-door patient at one of the London Hospitals, and desired to be treated for spitting of blood. The sputa, or spittle which she brought with her, was colored with blood, but the other symptoms did not tally with this one. The physician quietly made a microscopic examination, and then asked her if feathers had yet begun to grow in any part of her body? She said "No." "That is very strange," said he, "for your blood has turned into chicken's blood, and your hair ought of course to turn into feathers." Seeing that her attempted deception had been detected, she confessed that she had killed a chicken and mixed its blood with her sputa, so as to convince the physician that she was sick, and then obtain, as out-door relief, those delicacies which such people need. Those who will compare Figures 3 and 5 in our plate, will find no difficulty in seeing how the physician detected the fraud.

Another striking case in which the attempted palming off of human blood for

that of a fowl occurred to Dr. Leidey. A man was found murdered by the roadside near Philadelphia, and a market-man was arrested on suspicion. His wagon was found stained with blood, which a microscopical examination proved to be human. His explanation of the blood-stains was that he had carried some grouse to market and their blood had soaked into the wagon-bed. The microscope showed positively and clearly that he lied upon this point, and the jury very properly convicted him of the murder. He afterwards confessed.

In a future issue we will tell our readers how to use their microscopes in the examination of blood, and will describe the best methods of showing that which is probably the most wonderful revelation in the whole field of science—the circulation of the blood in the veins of the living animal.

Sharpening Wood-Working Tools.

BY "OUR NED."

"I DONT see how it is that I can't get my planes to work as nicely as they used to do. They don't seem to be able to cut so sweet or make such silky shavings. I don't understand it. I sharpen and sharpen until I have nearly worn out my oil-stone, yet, although I make them sharp, I can not get good results."

Such were the words of a young amateur friend of mine, who was the happy possessor of a good "kit" of amateur's tools, including a lathe, a good-sized scroll-saw, and a fine lot of carving tools.

His complaint was made to me, with a request that I examine the tools and find out, if I could, where the trouble was, and to suggest such remedies as might, in my judgment, correct the evil.

I examined the plane he particularly referred to, and found that the cutter iron was very dull and stubbed. This condition of things was such that it was impossible to keep the cutter sharp, for the least wear on the cutting edge would be sufficient to render the tool dull and incapable of doing good work. I show, in Fig. 1, the shape of the cutting iron as I found it. Now, by examining this figure, it will be seen that the cutting edge, A, when pushed forward, will work more like a scraper than a cutter, owing to its stubbedness, and that in fact the back of the basil, *i e*, the bevel of the iron at B, pressed against the wood at the back of the cutter, thus preventing it from performing its proper duties. To make this cutter right, and capable of doing its duty, I ground the tool until the basil assumed the shape as shown at Fig. 2. It will be seen that the cutting edge at A is more acute than at Fig. 1, and that the basil, B, in Fig. 2, is longer than at Fig. 1. It will also be noticed that on Fig. 2 there is a second bevel, *e*. I explained the use of this second bevel to my friend as being quite necessary to insure good and effective work. I repeat the explanation here: If a cutter is ground down to its cutting edge, so that the line of the basil forms

Fig. 1.

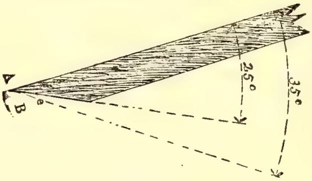


Fig. 2.

an angle of 25° with the face of the tool, as shown at Fig. 3, then by examining the cutting edge, B, it will be seen that it presents a very weak section, much too weak to be lasting or of much service. Indeed,

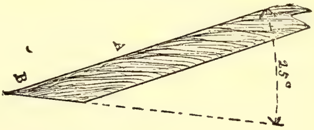

Fig. 3.

a plane-iron or chisel intended for general use, ground to this form, would be apt to crumble or "nip" out on the cutting edge, or if the temper is so fine that no crumbling takes place, the chances are that, in the case of a plane iron, it will "chatter" or spring and shake during

the operation of cutting; this makes the work wavy and full of transverse ridges, thus rendering the work unsatisfactory. Notwithstanding these defects, it has been ascertained that an angle of 25° is the proper one to employ when grinding tools for wood-working. To guard against the defects mentioned, a second basil is made at the cutting-edge at an angle of 35°, as shown at A, Fig. 4. It will be seen

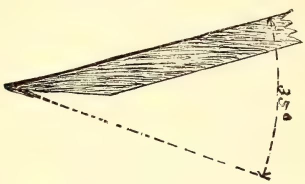

Fig. 4.

that by this method all the defects of the thin cutting edge are avoided, and all its advantages maintained. In grinding, care should be taken to avoid finishing down to the edge, for if such is the case the edge would be ragged and broken up, and would have to be whetted down on the oil-stone a full 32nd of an inch before the cutter would be ready for use.

In grinding tools of this character, the stone should revolve *from* the operator; that is, the top of the stone should move away from, not towards the tool. This gives the operator better control of the work, and gives him an opportunity to see when to cease grinding, which should occur when the basil is brought to within about a 32nd of an inch of the edge. The process of sharpening should be completed on the oil-stone at an angle of 35°, as shown at Fig. 4.

This second basil need be no more than a 16th of an inch from the cutting-edge to its termination on the line of basil; a 32nd of an inch is quite enough for the first few whettings after the tool is ground. Another thing I warned my friend against, and that was making a rocking motion of the hand while whetting the cutter, as this motion has a tendency to give the basil a convex or rounding shape, something like that shown at Fig. 1, which after a while destroys the cutting qualities of the edge. During the sharpening process on the oil-stone, the tool should be held firmly in the hand, with the thumb on one edge and two forefingers on the upper side of the iron, as shown at Fig. 5, with the end resting

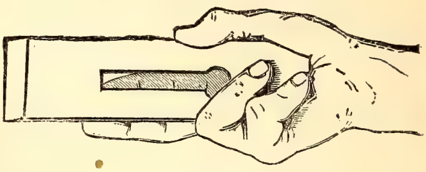

Fig. 5.

against the ball of the hand. The tool should now be placed on the stone and the left hand brought over and pressed on it as shown at Fig. 6. Sometimes the operator will find it more convenient to rest the three forefingers of the left hand on the iron while sharpening; on the whole, however, I prefer running the

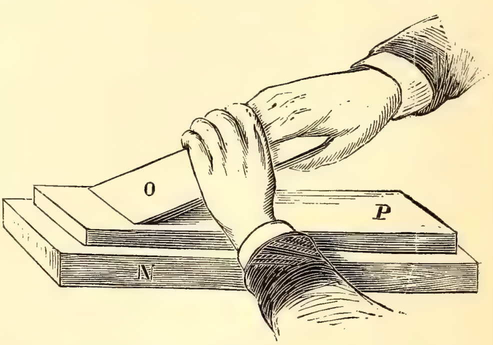

Fig. 6.

hand over, as shown in the illustration, as it enables one to take a very firm hold of the tool. With chisels, gouges, and other handled tools, it is better to lay on the fingers of the left hand than to grip it with the fingers, as it is not absolutely necessary that the cutting edges of these tools should be in a right line, or strictly at right-angles with the edges of the iron. With plane irons this is different; the cutting edge *must* be a right or straight line, and at right angles with the edges of the iron on the smoothing-plane, fore-plane, and long-jointer, but it

is not necessary to be so particular with the jack-plane; indeed, it is sometimes better to leave the edge of the cutter a little rounding, as it works better then for roughing off stuff and preparing it for the finer-working planes.

Another very important matter is the taking off of the corners of the plane irons, so as to prevent the tool from leaving marks on the work, which will be the case if not provided against. It will be seen by examining the iron, O, Fig. 6, that the corners show clear and acute. Now, if the cutter, O, is tipped up a little on the the oil-stone, P, and the corners gently whetted off, the iron will cut sweetly and smoothly without having its efficiency reduced in the least.

It will be seen that the oil-stone, P, in Fig. 6, is surrounded with a wooden case, N. This case serves a two-fold purpose, it protects the stone from breakage, and tends to give it weight and solidity while being worked upon. To make this case, a piece of dry pine should be obtained, about 1¼ inches thick, and about 1 inch wider than the stone, and from 1½ to 1¾ inches longer than the stone. A recess is then made from a half to three-quarters of an inch deep, according to the thickness of the stone. A cover should also be made of wood, to fit loosely over the stone, and which might have its corners bevelled off to give it an appearance of lightness.

All these things being fully explained to my young friend, we set to work to put his tools in order accordingly, and he was astonished and pleased at the result.

On examination of his saws, I found that they sadly needed overhauling and putting in order. This was a more difficult operation, but I undertook the work, and succeeded admirably. In another paper I will explain how this was managed.

— Flannel that has become yellow from being badly washed may be nicely whitened by soaking it two or three hours in a lather made of one-quarter of a pound of curd soap, two tablespoonfuls of powdered borax, and two tablespoonfuls of carbonate of ammonia, dissolved in five or six gallons of water.

Indian Clubs, and the Way to Use Them.

BY JAMES C. SQUIRES.

MANY people who have heard the term "Indian Clubs," are under the impression that these gymnastic implements first originated among our Indian tribes. This is a popular error. "Indian clubs" were used in the East Indies, Persia and China years before the discovery of this continent by Columbus. The date of their introduction into Christendom is unknown, but it is said that we are indebted for them to a military officer who had seen them in use by the Persians. The movements that can be performed with the clubs are almost unlimited in their variety, and are amongst the most useful and beneficial of any gymnastic exercises, having the effect of increasing the muscular power of the shoulders and arms, strengthening the hands and wrists, opening the chest, and also possessing the advantage of rendering the user ambidextrous, or two-handed—that is, of making the left arm, shoulder, etc., as vigorous and able as the right, and developing equally both sides of the body.

If practiced properly, the exercises are exceedingly pretty and graceful, and cause the performer to acquire a good carriage and deportment. Although in almost every gymnasium Indian clubs are now to be found, it is surprising how seldom they are used, the pupils generally preferring to acquire proficiency in the more showy feats that other instruments—such as the horizontal and parallel bars—permit of their practicing. But we would impress upon our readers that if they will only exercise a little patience and perseverance in acquiring the use of the clubs, they will find that no other gymnastic exercises can surpass them in grace and utility, and give such pleasure both to the performer and his audience.

The advantages of the clubs are many; amongst others, (1) they are inexpensive; (2) there is no danger attached to their use; (3) being portable, there is no fixing required—they can be used

either in the open air or in a room; (4) their weight can be adapted to the age and strength of the user.

With regard to the price, they can be obtained of any wood-turner at from 6 to 12 cents per lb. (unpolished). We should certainly recommend the learner to purchase *un*polished clubs, for in the course of practice he is sure to bruise them by knocking them together, and the damage shows more plainly upon a polished than an unpolished surface. But when he has become accustomed to the manipulation of the clubs, then he may obtain the more showy article.

Of course, every boy will know that the clubs are made of wood; elm is the best kind and mostly in use. Sometimes they are turned out of a lighter wood—such as pine—and are weighted to the required extent by molten lead being poured into a hole at the bottom of the club; but we must caution the would-be "clubbist" against buying such an article, for the weight should not be concentrated at the *bottom*, but should be contained in the wood itself, which allows of the club being properly *balanced*, without which true grace and elegance can never be acquired.

As to the shape, that most generally in use, and which is decidedly the best, is shown in the accompanying illustrations.

We now come to a most important consideration—viz., the weight to be used, which should be in proportion to the strength and weight of the performer. It is almost impossible to lay down any law upon the subject, but the following scale may be taken as a guide:

For a boy of	10	years old,	$2\frac{1}{2}$ to 3 lb.	each club.
"	11	"	$3\frac{1}{2}$ to 4 lb.	"
"	12	"	$4\frac{1}{2}$ to 5 lb.	"
"	13	"	$5\frac{1}{2}$ to 6 lb.	"
"	14	"	$6\frac{1}{2}$ to 7 lb.	"
"	14	and over	$7\frac{1}{2}$ to 8 lb.	"

These figures refer only to the light clubs or dual exercises—that is, when a club is used in each hand. For the single, or "heavy club" exercises, of course, the weight can be increased, but of that we will treat later on.

Many of our readers may consider these weights "a mere nothing," and quite unworthy of their muscular powers. But it is a great mistake to suppose that the benefit to be obtained from Indian clubs is in proportion to their weight, and in the exertion required in manipulating them. On the contrary, the easier the exercise (within reasonable limits of course) the better, for practice being then a pleasure, can be sustained for a longer period, and by this means the muscles become gradually developed, and subsequent fatigue is avoided.

We have said that the weight of the club should be in proportion to the *weight* of the user. We will justify this advice by an explanation. We will suppose that a boy of twelve years of age weighs 84 pounds, and another boy of the same age weighs 91 pounds; the latter, (presuming both boys' muscular development to be about equal) could use a heavier pair of clubs than the former, because he would have greater weight in his body to counterbalance the weight of the clubs.

In order to impress our young friends with the correctness of this principle we would point out to them that in performing exercises upon a fixed gymnastic apparatus (such as the horizontal bar) the gymnast has only to use muscular exertion proportionate to his bodily weight. If, however, he were to carry about him any weighty articles, or even wear a pair of heavy boots, he would experience a greater difficulty in performing the exercise, and perhaps fail altogether, and his exertions would soon produce fatigue. Therefore do not be too ambitious in selecting your clubs, but be contented with the weights we have recommended, which, although they appear small *on paper*, will be found quite heavy enough *in practice*. The writer, who has used the Indian clubs constantly for the last ten years, never has a pair of greater weight than eight pounds each.

The length of the clubs must be varied to the height of the performer. With the clubs standing on the ground and the hands hanging down, as in Fig. 1, there should be a space of about two inches between the handles and the tips of the fingers, so that it becomes necessary to stoop slightly in order to grasp the clubs. When swung round they should

clear the tops of the toes by about two inches.

With regard to dress, the ordinary gymnastic suit, shown in the illustration, is the most suitable. The best material to make it of is undoubtedly white flannel. A pair of flannel pants made to fit the

Fig. 1. Fig. 2.

legs tolerably closely, with plenty of room in the seat (not baggy of course), a close-fitting ordinary undershirt minus the sleeves (to give freedom to the arms), and a pair of canvas shoes without heels, are all that are necessary for wear during actual practice. Add to these a loose jacket of medium thickness to slip on during intervals of rest, and you have your costume complete.

But for Indian club exercise a special costume is not indispensable—and here, again, their economy is manifested—and all that need be done is to divest oneself of coat, vest, and over-shirt, and practice in ordinary pantaloons, boots, and undershirt.

Before proceeding to describe the different exercises, we would impress upon the reader most emphatically that in endeavoring to perfect himself in them he should bear in mind that, performed *gracefully*, and with an easy, swinging motion, there is nothing prettier. On the other hand, a jerky and strained action spoils entirely not only the effect from a spectator's point of view, but also neutralizes the benefit that should accrue to the performer.

First Position (Fig. 1). Place the clubs upon the ground, one upon the right and one upon the left side, slightly in front—about level with the toes. Stand at attention, head erect, shoulders square. Then bend down, grasp the clubs, one in each hand, and raise them up until the hands are level with shoulders, at the same time separating the legs and placing the feet apart, toes pointing outwards (as in Fig. 2).

Fig. 3.

You will then be in position to commence *Exercise* 1 (Fig. 3). Throw out the clubs to the right, and describe a complete circle with them in front of the body from the right to the left, *keeping the arms perfectly straight and in a line with the clubs.* As they describe the circle the body should be turned slightly in the same direction, and the head and eyes also should follow the course of the clubs from right to left. Continue this exercise at least a dozen times. Should you find any difficulty in accomplishing this with both clubs at once, try one at a time, first with the right hand and then with the left, or *vice versa.*

Here we will take the opportunity of informing the learner that he should en-

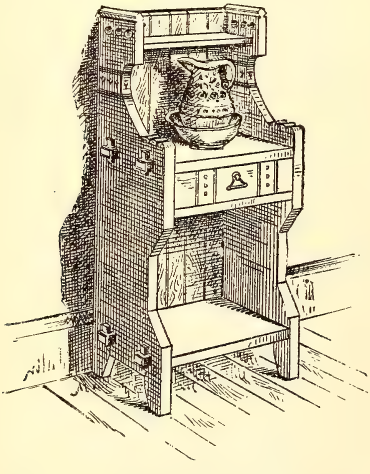
deavor to *identify* himself, so to speak, with the clubs, and consider that they are parts of himself—continuations, in fact, of his own arms. The base of the club should always be kept in a straight line with the shoulder. By this means an equal distance is preserved between the two clubs; otherwise, should they be swung at an angle, they must surely come into collision in the next exercise (and in many others to follow), and in which one club travels in an opposite direction to the other.

(To be Continued.)

A Simple Washstand.

FOR simplicity of construction, neatness of design and compactness, in the way of a washstand, such as can be made by an amateur, we have seen nothing that will compare with the one shown in the accompanying illustration.

The sides are formed of clear plank, and are mortised for the shelves. The scroll-saw may come into play in cutting out the sides. Three holes are bored in each of the sides near the top, as may be



WASHSTAND.

seen. These holes are about one inch in diameter. A little spray is incised around the narrowed parts of the sides, but this operation may be dispensed with if the amateur does not feel equal to its performance.

Each of the main shelves has two tenons left on each end to fit into the mortises made through the sides. The tenons have little wedges inserted in their ends to draw the sides of the stand snug up to the shoulders. The narrow shelf on the top, and the shelf supporting the drawers, are made of thinner stuft than the two main shelves, and may either be housed—*i.e.*, let in to the sides—or they may rest on little cleats screwed neatly under them.

The back is formed of thin stuff, tongued and grooved together, and is screwed to the shelves and sides. A little cap or coping is nailed or screwed on the top of the back, and buts against the two sides.

The drawer is made in the ordinary way, and has one of Shannon's brass or nickle-plated drawer pulls attached. The lower part of the sides may be left straight down from the drawer, and a valance or other drapery may be hung from the shelf under the drawer, by means of a metal or wooden rod, with sliding rings to which the drapery is fastened; or a simple fringe might be hung under the drawer.

The wood used in making this stand should be of a lightish color. Ash, oak, chestnut, or any of the pines, will look very well if properly handled. Of course the wood must be left its natural color, and filled with a "wood-filler" of some kind, and then varnished or polished. Wood-fillers can be obtained from any dealer in paint, oils, etc., and the directions for their use are generally pasted on the can containing the filler.

As soon as the stand is made, steps should be taken at once to have it varnished or polished, for the woods named are extremely porous, and if dust or dirt once gets into the pores, it will show through, no matter how much filling or varnish may be applied, and the only way to neutralize the effect is by staining the whole work dark.

This makes a very neat piece of furniture, and is in the prevailing fashionable style, being Queen Anne in character.

Walking-Sticks: How to Make Them.

BY GEORGE EDWINSON.

AT most periods of our lives we display a fondness for sticks. Even in the palmy days when vigorous manhood does not require a staff to support his tottering footsteps, he invents some other excuse as a reason for carrying a stick in his hand, and feels still more lonely in his lonely walk if he happens to have left the mute companion of his travels at home. A variety of tastes are displayed in the selection of walking-sticks—tastes not always governed by the necessities of the selector, nor by the fashion of the day, but sometimes by some peculiar idiosyncrasy of the individual. Hence, whilst some prefer a lithe holly stick, or hazel, others prefer ash or elm, others are content with nothing less than a stout oaken cudgel, and a son of Erin would revel in a tough little bit of blackthorn in preference to all other woods. Some again scorn our homely woods and will carry nothing commoner than a foreign cane or bamboo fitted with a head of gold or silver; others prefer those with grotesquely-carved heads, and not a few take a pride in carrying a stick cut or pulled by their own hands from hedge, copse, or wood. But a stick thus pulled or cut is apt to betray the ignorance of its owner by its rough head, its cracked and scored shaft, its crookedness, its rough bark, or its unpolished condition. To meet the wants of those who would like to prepare such sticks for themselves, the following hints are given, and may not be unacceptable.

Walking-sticks should not be cut or pulled in the spring later than the month of February nor earlier in the autumn than the month of October; the best time of the year being from the first week in December to the last week in February. Sticks should be laid aside in only a moderately dry cool place, and should not be worked nor the bark taken off until they are half dry, then they are most supple and may be bent or straightened without injury. In laying by sticks to dry, the knots should not be trimmed close—in fact, it is best to only rough-trim the stick, leaving the spurs of branches and of roots on the stick fully an inch long. The following kinds of woods are pulled and cut for walking-sticks in addition to others not enumerated here.

Holly.—Sticks of this wood are found growing out from the side of older stems, and shooting up in nearly a straight line through the dense foliage above. Occasionally they may be cut with a crutch piece across the growing end, or with a crook or knob. These are the most valuable. Luck may sometimes happen on a well-grown sapling in the deep wood, this should be pulled or dug up for the sake of its roots. Saplings and hedge sticks may often be found, from 3 to 4 feet long, with the top part to the length of a foot, from $\frac{3}{8}$ to $\frac{1}{4}$ inch in diameter; these are not suitable for walking-sticks, but they make excellent whip handles, and are used for this purpose by country teamsters. Holly sticks should only be rough-trimmed when green and put away in this state to season. They make tough, supple, and moderately heavy walking-sticks, and their closely grained wood admits of the carver's skill being exercised on the knob, formed by the root and its rootlets.

Ash.—Respectable sticks of this wood may sometimes be cut out of a hedge, or pulled from the side of an old stump or pollard, but the quality of such sticks will not compare with that of sapling ash, pulled or dug up in some copse or wood. Sapling, or "ground" ash, as it is called, vies with holly for toughness and suppleness, whilst sticks of equal size yield the palm to ash in point of stability, but to holly for durability. Hedge sticks of ash get brittle as they get dry and old, and the same remark applies to most sticks pulled from old stumps. Ash sticks must also be rough-trimmed and well seasoned before they are barked and polished. The wood and curiously formed root-knobs of ground ash will admit of excellent grotesque carving.

Oak.—This of all sticks is the most reliable, and stout oaken cudgels are esteemed by most persons as some of the best props to failing legs, as well as the

best weapons for self-defence against quarrelsome dogs and rowdy ruffians. Straight sticks of sapling oak are not always easily obtained, but copse-wood sticks pulled from the stumps of trees form excellent substitutes. These should be selected for walking-sticks which taper gradually from $\frac{3}{4}$ of an inch just below the knob or crutch, down to $\frac{1}{2}$ inch at the opposite end. Gnarled and crooked oak sticks are sometimes fancied, and heavy cudgels are sometimes selected for defensive purposes. Oak sticks split in drying when the bark has been stripped off, or the knots cut too close, or the sticks put away to dry in a very warm dry place; they are then rendered useless for walking-sticks and cudgels. The wood and also the form of the knobs or roots will admit of much taste being displayed in grotesque carving.

Elm.—From the roots of elm trees, saplings with a coating of rough bark will shoot up straight to a height of some ten or twelve feet. These will furnish some good walking-sticks of the fancy type, the rough bark serving the purpose of ornamentation when the sticks are dried, stained, varnished, and polished. The wood is also durable, but not very supple when dried, and sticks of it are not suitable to hard usage. The usual precautions must be taken in drying them.

Hazel.—Light sticks of this wood may be cut or pulled from almost every hedgerow and in any wood. Saplings are not unfrequently found of most symmetrical proportions, tapering from 1 inch down to $\frac{1}{4}$ inch through a length of some ten or twelve feet; these form very tough sticks of any desired size. The wood is very light, but it has the disadvantage of bending and remaining crooked when leaned upon heavily. It is also soft, and may be easily carved. Occasionally, hazel sticks may be found grotesquely entwined with honey suckle, and its stem so deeply furrowed with the supple vine as to enclose the convolutions of the climber. Sticks of this kind are valued as fancy sticks, and look well when properly prepared, varnished and polished.

Blackthorn.—This is the wood of the bush which bears the sloe, and the bullace or wild plum. In exposed positions it is only a dwarf shrub, but in sheltered hedgerows and woodlands it attains a height of some twenty feet, and its saplings run up to a length of from six to eight feet straight and taper, but covered with stout spines and small twigs. Those saplings make excellent walking-sticks, both when they can be dug or pulled up, and also when they have to be cut off. The spines and twigs must not be cut off close until the stick is half dried, and then cut with a sharp knife; in fact, the knots left from the spines and twigs when left as slight round excrescences enhance the beauty of the finished stick. Blackthorn is more famous for its hardness, strength, stability, and durability than for lightness, elasticity, and suppleness. A cudgel made of blackthorn will deal heavy blows, but when matched against one of oak would splinter at the knots, the oak being the tougher stick. The wood is hard and not easily carved, but the root knobs will admit of a very fine and smooth polish, most grateful to the palm of the hand of the tired pedestrian. Its congener, the whitethorn, or hawthorn, is not so suitable for walking-sticks, being more brittle and less durable, but it is sometimes used for this purpose.

Among fruit trees, the cherry will furnish some very nice fancy sticks, supple, and of tolerable strength; and apple wood, when well and carefully dried, will yield some good sticks. Grapevine and briar sticks are sometimes used, but they cannot be relied upon for stability when leaned upon.

When sticks are half-dried, that is, when the bark is shrunken, has lost its sappy greenness and refuses to peel freely, they may be trimmed, straightened, or bent as required. To straighten or to bend them, they may be held over steam until rendered supple, or buried in hot wet sand until this end has been attained, they must then be given the form they are intended to assume (whilst still hot), and kept in this form until they are cold, straight sticks being tied firmly in small bundles, and wound with a coil of rope from end to end, or suspended from a beam

by the knob end, whilst a heavy weight is hung from the small end. Crooks may be turned by immersing the end in boiling water for five or ten minutes, then bending it to the desired form, and securing it in this position with a tourniquet (Fig. 1) until the stick is cold. The bark may next be taken off with a sharp knife, if so required, and care must be taken not to splinter or chip the wood of the stick. then any amount of skill in carvings may be expended on the knob; but if the stick is for use, we should first consider its use. Round smooth-headed knobs (Fig. 3) carved and polished to fit comfortably into the palm of the hand, will meet with most acceptance from those who use a stick as a support. But knobs thus formed, and shorn of a projecting crook or hook, often slip from beneath the arm or out of

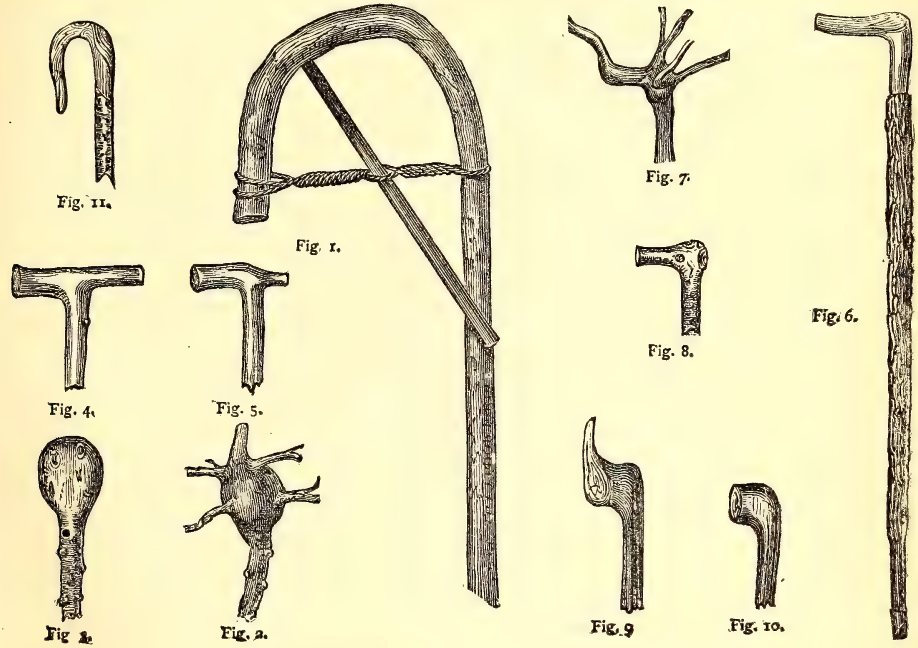


Fig. 1.—Crook Stick, showing method of turning crook by means of tourniquet. Fig. 2.—Blackthorn Knob, rough. Fig. 3.—Blackthorn Knob, trimmed. Fig. 4.—Crutch Form of Crook. Fig. 5.—Half Crutch. Fig. 6.—Elm Stick. Fig. 7.—Ash Root, as dug up. Fig. 8.—Ash Root, trimmed. Fig. 9.—Ash or Oak Knob, as pulled from pollard or stump. Fig. 10.—The Same, trimmed. Fig. 11.—Stick Bent and Trimmed to form Crook.

Knots may be trimmed at the same time, and the knob trimmed up to shape. Hard and fast rules cannot be given for the formation of knobs, since their form must be regulated by the natural knobs, and these are often very suggestive in themselves. One or two things should, however, receive consideration in designing a knob, and the first should be the ultimate use of the stick. If the stick is to be a fancy one, to be carried and swung in the hand, more for appearance than for use: the hand when its owner wishes to use both hands for some purpose—for instance, to light a cigar or a pipe. The head of a dog with a long muzzle, the head of a swan or a goose, forms an appropriate design for such a stick. The crutch (Fig. 4) or half-crutch form (Fig. 5) is also a comfortable one, but the ordinary crook (Fig. 1) although useful for many other purposes, does not fit comfortably in the hand, it is too much of a handful, and the central support usually

finds its bearing under the forefinger instead of the palm of the hand. Sharp carving on the knob should always be discouraged, for it only hurts the hand, but the neck of the knob may receive the carver's attention. We shall avoid reference to fancy sticks with metal heads of gold, or silver, or silver plated brass, and to those clever contrivances, which store a *multum in parvo* of tools in the head of the stick; also leaving out of our consideration, the loaded stick with its half-leaden head, and that barbarous relic of the dark ages, known as the sword-stick—these we will leave in professional hands.

Elm sticks with the rough bark left on (Fig. 6) must be neatly trimmed naked around the neck of the knob, and at the bottom of the stick just above the ferrule, loose bark should also be neatly trimmed with a sharp knife, and the whole lightly gone over with medium glass-paper. The stick should then receive a dressing of boiled linseed oil, and be left to dry. When dry, it will be well to go over the smooth parts with a little polish, and finally give one or two coats of hard spirit, or of copal varnish. Holly, ash, hazel, cherry, apple, birch, etc., should have part of their bark only taken off with a sharp knife, leaving all knots smoothly trimmed, rounded, and clean. The sticks should be then lightly glass-papered, and when smooth, dressed with boiled linseed oil, dried, polished, and varnished. Oak sticks look best when carefully barked in hot water, cleared of the loose bark by rubbing with canvas, dried, dressed with boiled linseed oil, again dried, then polished and varnished with oak varnish. Blackthorn sticks should be only partly barked, the knots smoothly trimmed, then glass-papered quite smooth, dressed and varnished as directed for other sticks. Sticks may be stained black after they have been glass-papered, and before they are dressed with oil, by first brushing them over with a hot and strong decoction of logwood and nut-galls, and when this has well-dried, brushing over them some vinegar or acetic acid in which a quantity of proto-sulphate of iron, some iron rust, or some old rusty nails have been steeped some two or three days previously. A brown or mahogany tint may be given by adding some dragon's blood to the polish, and a yellow tint may be obtained by adding yellow ochre. Some persons use ink for a black stain, and others put drop black in the varnish, but the black stain above mentioned is preferable to all others. The sticks are to be polished and varnished after the stain is dry. The bottom ends of walking-sticks should be guarded from excessive wear by a neat brass ferrule, but these are more cheaply bought than made. They should be secured to the stick by two small screws, one on each side of the stick, to prevent them from coming off when they get loose in dry weather.

Amateur Brass Work.

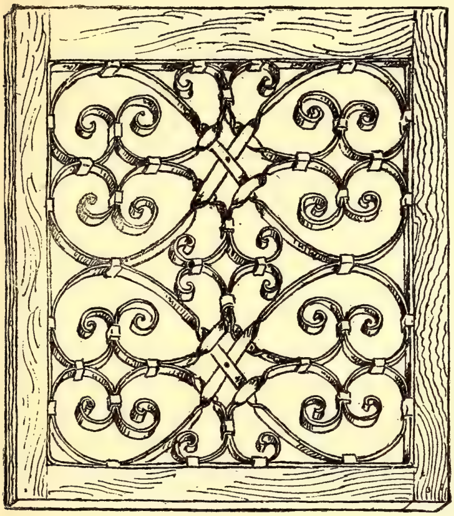
NO doubt many of our expert amateur readers would like to work in other materials than wood or iron, but are deterred from doing so by not knowing how to take advantage of the facilities offered by brass, bronze, stone, and other like materials. It is easy to see how wood may be converted into various uses and forms, but to the uninitiated the difficulties of employing brass for artistic purposes and yet be within the range of the amateur, are frequently magnified into insurmountable obstacles. Brass, however, and many other materials, may be worked with nearly as great facility as the softer substances, and in future numbers of the YOUNG SCIENTIST we intend showing how many artistic and useful things may be made by the amateur from the sterner materials.

The illustration shown herewith will give an idea how a metal grille or guard for a panel in a cabinet—to take the place of wood or glass—can be made quite readily out of narrow strips of any sheet metal, by simply bending with the fingers and a small pair of pliers.

Soft brass would be best for the amateur to try his hand on first, as it is tractable and easily worked.

The design should first be laid out full size on a board, when it will be found an easy matter to bend the strips of metal

into their proper shape. The fastenings at the intersections are pieces of the metal bent around and pinched tight by the pliers. A strip of the metal should be bent around and fastened to the entire

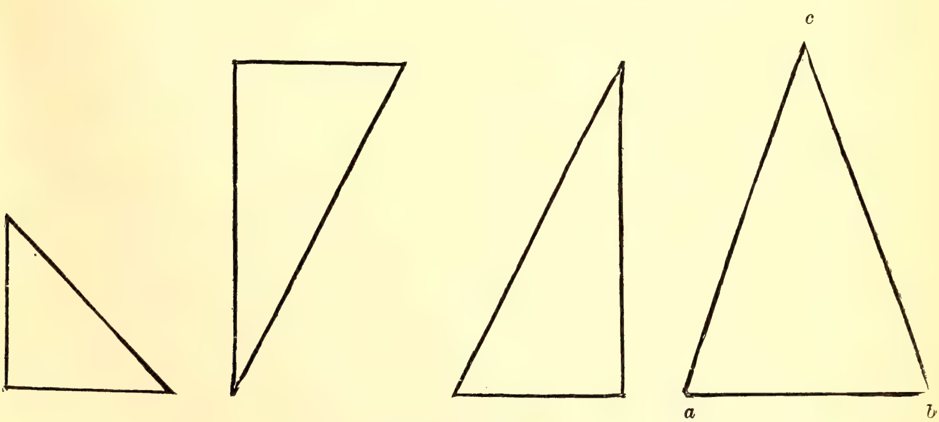


pattern for the purpose of attaching it to the stiles and rails of the panel or frame. At the intersection of the centres of each main section of the design, where the metal is twisted to show its flat surface to the face, rivets are used to hold the parts together.

This kind of work may be applied to a thousand different purposes. It looks particularly well when used in making a summer fire-place screen, and wrought of brass, lacquered, has a very rich appearance. Narrow hoop iron, strips of galvanized iron, zinc, heavy tin, or other materials might be used, each kind being suitable for some particular purpose. When hoop iron is used it should be either bronzed or japaned.

A Mathematical Puzzle and a Lesson in Geometry.

OUR very young readers who wish to exercise their mathematical abilities may cut out four pieces of cardboard, the exact size and shape of the figures given below, and try to put them together so as to form a perfect square. There are several methods of transferring the figures to cardboard so as to get the pieces the exact size and shape required. One is to lay the cardboard under the page, and stick a pin through the three corners or angles. The pin marks must now be joined by lines drawn with a ruler, and the figures will be complete. Another way is to draw the figures on transparent paper laid over the page, and then gum the thin paper firmly to the card, after which card and paper may be cut up as required. But the most elegant method is to draw the figures geometrically. Take the left hand figure to begin with and draw a straight horizontal line. Then with a pair of com-



MECHANICAL PUZZLE.

passes take the length of the line $a\ b$ and mark it off on the line just laid down. Now take the line $a\ c$ in the compasses, and with a as a centre, strike an arc at c. Do the same with the line $b\ c$ and the point at which these arcs cross is the point c. Then draw lines between $a\ c$ and $b\ c$ and the figure is complete.

In our next issue we will give an engraving showing the method of placing these figures so as to form an exact square.

Christmas Decorations.

BY A. W. ROBERTS.

SO many are interested in the subject of Christmas decorations, both for the home and the church, that I am sure a few hints on the subject will be welcome. In the way of material, there is an abundance to be found in all our woods. There is the hemlock, arborvitæ, spruce, laurel, ink-berry, holly, rhododendron, and the junipers and cedars among the trees and shrubs. Then comes the three varieties of club mosses, or lycopodiums, of which the variety known as "Bouquet Green," or ground pine, is most useful for small work. Then come our berries, catkins, and cones, and also the evergreen ferns. Next to these it is entirely proper to use pressed Autumn leaves and ferns. Also, from the garden may be obtained the golden and other varieties of the arborvitæs, box, English ivy, and other evergreens, which, by judicious selection and trimming, will afford useful material.

The immense trade in Christmas greens, which begins two weeks before the holidays, is one of the most striking features of Washington Market. These evergreens are procured from almost every part of the United States east of the Alleghanies. From the vast wilderness of Maine steamboat loads of Christmas trees are delivered at the Boston and New York markets. The cedar, lycopodium, and holly come from New Jersey and Pennsylvania; Virginia leads all other states on holly, laurel and bay, and England and Florida on mistletoe. It has become the custom, of late years, with English people, to send a living branch of mistletoe, as a Christmas present, to their friends and relations living in "the States."

When one sees the immense loads of

Fig. 1.

Christmas trees that are received at the market, he wonders what becomes of them, and who purchases them; and as they range in height from four feet to twenty-eight, and even thirty, and in price from twenty-five cents to $15, he becomes still more puzzled. And yet, even all these very small and very tall trees do not fill the bill, for even to-day, as I was obtaining my notes, a gentleman wished to obtain a tree forty feet high, and was willing to pay a dollar a foot for it. This tree was for one of the Brooklyn orphan asylums, and was to be hung and ornamented with all kinds of toys, presents, bon-bons, etc. Next to the trees

and loose evergreens, come roping, wreaths, stars and other emblems.

It is estimated that to decorate an averaged-sized sitting room or parlor

Fig. 2.

with first-class roping, wreaths, stars, and crosses, will cost from $3.50 to $4, and to my mind there is nothing prettier than a tastily decorated room at Christmas time.

This Christmas the æsthetic sunflower and peacock feathers will be extensively used, in combination with holiday decorations, also chromo pallettes and plaques, now so much in vogue. When decorating a room, particular attention should be paid to portraits of relations and friends that are deceased; these should receive marked tributes of greenery.

In purchasing evergreen emblems be sure to avoid everything that contains those abominable tissue-paper roses; also look out for wreaths, etc., containing the panicles of the terribly poisonous sumac berries, of which I saw many hundreds in Washington Market last year.* There are also many wreaths for sale in the market, composed of a light-grey lichen, which, as soon as it becomes dry, also becomes very brittle, and falls away. To increase the effectiveness of these wreaths, they are often dyed with cheap aniline dyes. One of the most effective, and at the same time ingenious ways of ornamentation, in conjunction with Christmas greens, that I know of, is the use of tissue-paper banners. These can be got up at a slight cost, and in designing them, all that is artistic and graceful in form, design, combination of colors and materials, can be displayed by the designer. These banners may be patriotic or religlous, or they may contain mottos and emblems significant of Christmas, or home mottoes, such as "Welcome to All," "Welcome Home," "Love One Another," etc., etc. The materials used being the best quality of tissue paper of the most brilliant colors, gold leaf and silver leaf—dutch metal will answer every purpose, and comes much cheaper than the real metals. Silver and gold papers are used for lettering and fringes, also blue and crimson paper for lettering. For staffs use painted dahlia sticks, which may be procured at any seed store; top them off with a pine cone touched up with gold leaf.

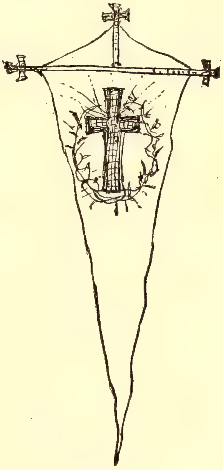


Fig. 3.

When using small wax tapers for illuminating the Christmas tree, the greatest of care must be taken when lighting them not to set the tree on fire, as it must be borne in mind that after a few days in a hot room these trees become very combustible, and flash up so quickly that not the least warning is given before the lace

* Since writing this article a case of very severe poisoning from the poison sumac, is reported from New Jersey. A lady, when decorating a church for the annual Autumn services, handled some of these poisonous plants, and was so severely injured that her life was endangered. In a future number we will give such descriptions and cuts of these poisonous plants as will enable our readers to readily recognize and avoid them.

curtains of the windows at which the tree stands are also on fire. The better way is not to place the tree at or near any window, but have it in the centre of the room. Flowers and plants in pots can always be used with great effect for Christmas decorations. To avoid the ugliness of the bare pots, cover them

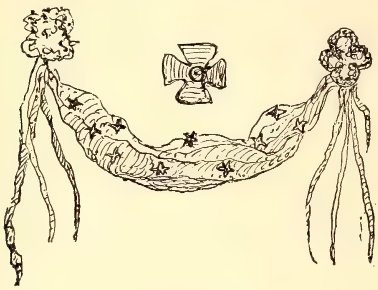

Fig. 4.

with sheet moss from the woods; this material may be fastened on with fine wire or thread. If the moss is not obtainable, bank up the pots with evergreens. I have sometimes seen very small hanging fish-globes, containing one small gold fish, so arranged as to produce

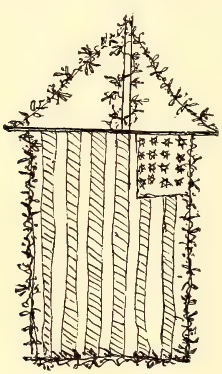

Fig. 5.

very beautiful effects. The best receptacles in which to plant or fasten the Christmas tree is a half butter tub nailed to a square piece of two-inch stuff. The tub, and the square of timber to which it is fastened, are painted green, and while the paint is moist, pulverized wood moss is dusted on it; don't attempt to represent a miniature picket fence, with wooden sheep and shepherdesses, but let it be an honest substantial butter tub filled with earth. I have made a number of offhand pen sketches as suggestions of shapes of banners and appropriate mottos. Fig. 1 shows how two styles of banners can be cut from one slip of paper with the least loss of material. Figs. 2 and 3 are cut out on the same principle, while Fig. 4 is a patriotic design, consisting of a festoon of red, white and blue tissue paper, bespangled with silver or gold-paper stars. The ends of the festoon are caught up with a rosette, from which streamers depend. Fig. 5 consists of a cheap muslin American flag, bordered with lycopodium trimming.

Our Girl's Department.

THIS department is intended exclusively for "Our Girls," and we hope to make it both interesting and instructive, and to this end we ask our young lady readers to assist by contributions, suggestions, or illustrations. There are thousands of little things that can be, and have been, made and done by young ladies, pertaining to decorative art, needlework, etc., etc., that would be gladly followed but for a want of knowledge on the subject, and we know of no more pleasing task for a lady than that of teaching her younger sisters that which they are anxious to learn, and which may prove of real benefit to them in the future, as well as being useful and interesting for the present. We trust we will have no difficulty in persuading those who have something nice to show or speak of, to make use of this department. Remember, it is open to all, and if you have anything worth knowing suitable for this column, send it along, and we will give it our best attention. Do not be afraid to write because you may fancy your composition is not perfect, or have other scruples of a similar kind. Do the best you can, and leave the rest to the editor of this department, and we are sure you will be pleased with your work.

THE WORK BASKET.

The style of netting shown in Fig 1, is sometimes called "letter B netting," because the pear-drops in the meshes form

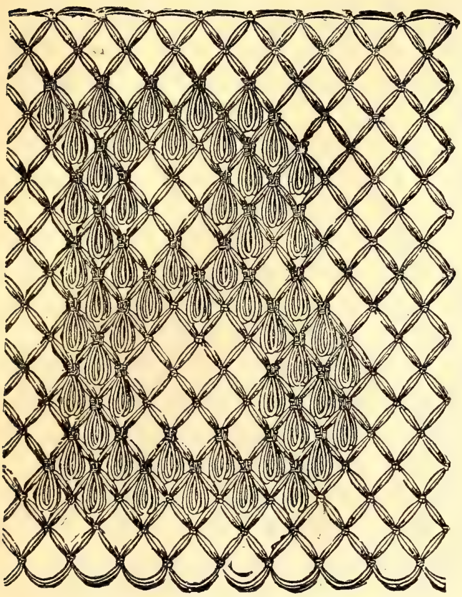

Fig. 1.

the letter. For working it a double strand is required for this netting, with a mesh of proportionate size. Any netter will find it easy to reproduce the pear-drops which dot the initial itself; they are formed by winding the thread or silk twice round the mesh after the stitch is completed, and securing those pendant loops by a knot. To allow them to fall nicely they are each separated by a plain stitch. All letters can, of course, be represented in the same pretty style, besides many simple patterns, as the diamond, star, etc. Indeed, cross-stitch designs would be a guide for borders and powderings executed in this method.

Such initials are used for sachets, night-dress bags, pillow cases, cushions, etc., but to show up well should always be lined with some bright-colored sarsanet or sateen.

Katie B—— sends the following: "For outline embroidery the simple ordinary backstitch is used. When the lines are required to be very fine they are worked in very fine; bring the needle out through the centre of the thread, instead of coming to one side of it. The stiches should be of the same average length and the outline should be followed exactly. Measure the distance with the eye and avoid a sudden shortening or lengthening of the stitch. Care must be taken in working to have the stitches lie flat. Always work with a short thread, as otherwise the silk or cotton will become rough. Never work with too small a needle, as it will drag the material.

Sadie R—— says: "To made a very pretty card basket, construct a framework out of stovepipe wire to the shape desired, then take about three pounds of alum and three quarts of water, boil until the alum is dissolved. Suspend the wire basket in this solution, and let it remain for twenty-four or thirty-six hours, at the end of which time it will be found covered with beautiful alum crystals."

The manner of making the wire framework is very simple and will suggest itself. The basket, when made, looks very handsome. Many other things besides baskets may be made and covered with alum crystals by the same process, and it does not necessarily follow that wire be used in the construction of the framework. Cotton wrapping cord will, in many cases, answer just as well as wire, when it can be fastened to some substantial frame-work.

Fig. 2 shows a knitted check pattern, which is not difficult to follow. The blocks may be colored to represent some of the various tartans and devices of Scotland; but here, to prevent the extra thickness gained by carrying the wool across at the back, each check is made separately on the bias, and deftly knitted together. Hence, while the Scotch mode rather tightens the material, this new slantwise way gives it a great deal of elasticity, so much so, that when used for stockings, one-third of the ordinary stitches may be suppressed.

In the cut, the blocks are eight stitches square, and of two colors; but when selected as borders for petticoats, quilts, etc., much larger squares can be obtained

by calculating from twelve to sixteen, or twenty stitches, and taking coarser wool. Also more diversity may be introduced into the coloring by the blending of several contrasting hues, or the artistic shading of one color, from the lightest to the darkest shade, and *vice versa*. Even when executed in a single tint the blocks can display change, by intermingling with the plainly-knitted checks others of purl, ribbing, moss-stitch, etc. To work the pattern, take any number divisible by eight, according to the size required. For the four checks of the illustration cast on thirty-two stitches, and set them, if for large work, by one plain and one purled row. 1. Half squares.—Knit plain, with the darkest color, eight stitches; leave the remaining twenty-four aside, turn the work, and with a third needle purl back, taking the last two stitches together. Repeat this at every alternate row, till there is but one stitch left on the needle. Thus in the third row you will knit seven, in the fifth row six, in the seventh row five, in the ninth row four, in the eleventh row three, in the thirteenth row two, in the fifteenth row one. Your reductions have been made on one side only. Now, with the needle which bears the one stitch, pick up and knit seven stitches along the opposite side, which will bring you back to the twenty-four stitches. In raising the loops, take up the *back* part of every other stitch. Leave this needle untouched. The first triangle is complete; proceed to the following one by knitting

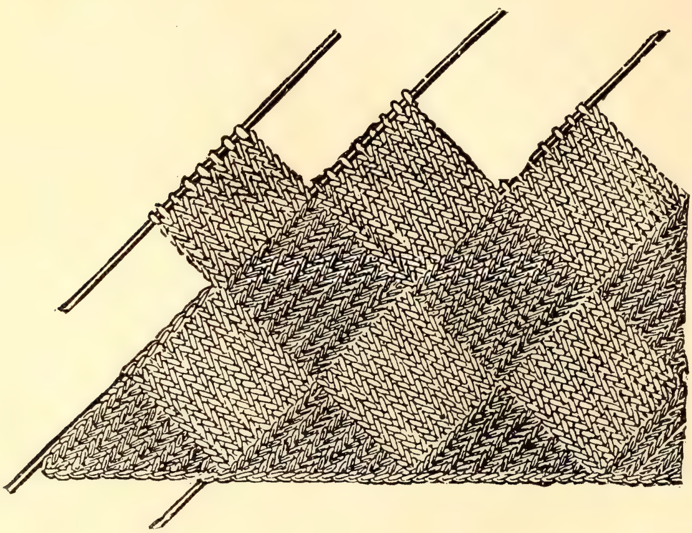

Fig. 2.

off eight more loops, and decreasing them as before; pick up the stitches of the straight side again, leave them on the needle, and continue in the same way to make two more triangles with the sixteen remaining stitches.

Second row. Complete squares.—The first row has produced four triangles, on each of which has been left a needle holding eight loops. These sets of loops form the foundation of squares which, sloping in a reverse direction, fill up the spaces between the triangles. They are likewise made separately, and joined to the side of the half-squares whilst working. Proceed thus:—With contrasting wool, purl the eight loops of either the first or the third triangle; it does not signify at which end you commence. Knit back seven of the stitches; then slip the last loop off on to the needle already full. With the needle now at liberty, lift up the back part of the first stitch on the de-

creased side of the next triangle; pass the eighth, or unknitted loop, on to its own needle again, and knit the two together; but *from the back*, for the last loop of the square being made, always falls *over* the picked-up stitch. Return by purling, and continue in each knitted line to raise a stitch from the side. As eight are to be picked up, every alternate loop will, of course, be taken. Remember, also, to seize the front part of the side loops, to avoid showing any ridge. When the first square is completed, leave the eight loops, as before, on the needle, and proceed to work on the loops of the following triangles in the same manner.

Third row.—Here we have another series of squares or diamonds fitting into those below; they are executed on a like principle, but in a contrary direction, their slope corresponding to that of the triangles. Raise eight loops with the dark wool again; this time on the right instead of the left side of a block; purl them, turn, and knit together in the ordinary way, the last loop of the light square, and the first loop of the fresh one, taking care that the latter falls well over. Take two together, thus, at the commencement of every knitted line, and when the block is made, leave the loops on the needle, and pass to the next square.

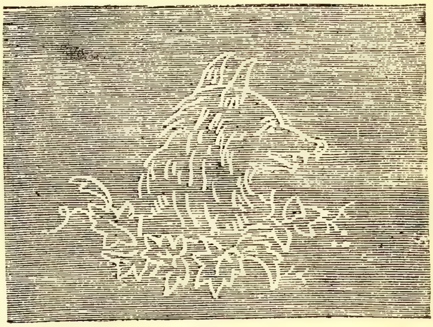
The second and third rows comprise the whole work, and having repeated them as often as desired, make the top straight by introducing triangles, as at the lower edge.

The numerous needles will be found rather troublesome, especially at the beginning of the work. To obviate this drawback each square may be cast off as it is finished, and which does not prevent the stitches from being picked up, just as if the needle were there.

Figs. 3 and 4 show a pair of sprightly designs for handkerchief ornaments, and give an idea of one popular style of ornamenting a gentleman's pocket handkerchief, more especially when their owner is of a sporting turn of mind. Figs. 3 and 4 are each completed by a semi-wreath of foliage, which may be copied in colored cotton or washing silks; the hues chosen according to the deep border which generally frames these handkerchiefs, whether in silk or linen. Naturally the embroidered corner will always be the one that so carelessly, yet so intentionally, escapes

Fig. 3.

from the breast pocket of the fashionable coat. The same taste for animals' heads is noticeable in many other etceteras; a cat or a dog, closely worked in crewel or chain



Fig, 4.

stitch, peers from slippers, handkerchief and tie cases of padded satin, and even scent sachets have lately been decorated with velvet *appliques* of mastiffs, spaniels, etc. The two heads, Figs. 3 and 4, are quickly executed in outlining with the ordinary twist stitch.

— Among the pretty new things are the lamp screens used of late, since lamps began to play so important a part in household life. The screens take the form of oblong or shield-shaped bannerettes, and are hung from silver chased or

gilt standards. A very pretty one has a centre of pale pink satin upon which is painted a small landscape, this is set in a wide frame of grey plush, decorated with a loose drooping spray of wild roses.

— A handsome mantel drapery is made of terra-cotta Japanese canvas, the two ends of which are heavily scolloped. The centre is a piece of deep crimson velvet, upon which a design of sumac blossom is worked in arasene.

— Transparencies are displayed of a material called Miller's muslin, upon which exquisite designs can be worked in long stitch. These transparencies are framed in ebony or ebonized wood, and placed where they can transmit the light.

— Small banner screens for a bracket or mantel are painted in oil colors upon white satin. Carved stands for them can be bought at any fancy store, and the addition of thin white silk cord and tassels makes them very effective.

Prisoners' Pastimes.

BY A. W. ROBERTS.

POVERTY makes strange bedfellows, is an old proverb, and it may with equal truth be said that the pursuit of science makes strange companions.

Little I thought when starting from the New York Aquarium on that particularly exhilerating and sunny Monday morning, that I would, before the day had ended, have accepted the companionship of two professional criminals, one a notorious burglar and the other well—no matter; but so it came to pass. My object was to obtain anemones;* the beautiful dianthus anemone, neither the small long-armed variety, nor the small but exquisitely salmon-colored one so plentiful on the rocky shore of the East River, in the neighborhood of Eightieth Street. No; neither of these would satisfy the ambition and pride of an expert collector. In this particular instance I felt extremely anxious for success, as all the large anemones at the Aquarium had from some unaccountable reason suddenly collapsed. When connected with Barnum's (old) Museum Aquaria the dianthus anemone was plentiful on the rocks about Hell Gate, but within the last twenty-five years numerous oil, gas, acid and other works had become established at Greenpoint, Hunter's Point, and along the shores of Newtown Creek, and hundreds of submarine blastings had taken place at Hell Gate. Turning over in my mind all these facts, and knowing from experience how the rocks along both banks of the river are more or less coated with the villianous materials that pour into the East River from these establishments, it became a question of no easy solution where to obtain the much-desired marine animals. After some deliberation I concluded that my only chance, my only hope, was to visit that renowned, secluded, and very private locality, commonly known as Blackwell's Island. But how was I to get there? That was the rub! I had plenty of letters in my pocket to prove my identity and occupation, not to mention a goodly supply of free passes to the Aquarium, but these were of no use where political influence was the chief, perhaps the only passport to favor. In this dilemma I called to mind that an old friend, whom for short I call "Cush," reigned supreme at the Morgue as deputy coroner, and was well paid for supplying the brains—medical, anatomical and scientific—needed at the coroner's office. I sought him at once, and in a few moments I had obtained two documents, one passing me on to the little steamboat that plys between New York and the lonesome isle, the other introducing me as one of the faithful to the Grand Mogul of the Island of Concentrated Sin. On the island I was passed along from one official to another, and at last into the guard boat. This boat consisted of a well-modeled, red cedar, copper-fastened row boat, containing two prisoners in full uniform of prison clothing. At the stern of the boat sat the guard, silent and som-

* As many of our readers may not be familiar with this curious and beautiful animal, we have prepared a description with elaborate drawings, which will appear in the next issue of the YOUNG SCIENTIST.

bre looking. I tried to take his measure, but could not get behind his rigid physiognomy. The two prisoners rested on their oars; their ages must have been thirty and forty. They were muscular and well appointed by nature in all respects, but on their ruddy and bronzed faces rested that unmistakable shadow peculiar to men in their position. And thus for a minute we remained silent, for we were mutually measuring each other. The guard was first to break the unpleasant silence, by asking "To what part of the island do you wish to go?" I answered "that I did not know exactly, but proposed to examine his side of the island thoroughly for a curious animal that lived on the rocks, called the anemone." Noticing that the name was beyond his mental reach, I made a hasty sketch of an anemone, but he failed to recognize it, although, as he remarked, "he knew every inch of rock and dock on the island, and he feared my search would be in vain." During this conversation the two prisoners remained motionless and silent. I knew they greatly desired to see my sketch, but I dared not hand it to them. "Well," I remarked, "there can be no harm in making a thorough examination if you have no objection." At which remark the slightest suggestion of a smile passed over his set countenance. 'Twas then that I became convinced I had struck his weak spot—vanity—and to a limited extent he was my prisoner and I a free man. Now be it known that in my pockets were numerous packages of both hard and soft tobacco, and my heart was fairly aching to get it into the pockets of the prisoner oarsmen, for next to freedom or money, tobacco is the most prized of all gifts. They chew it; they devour it; in fact, they fairly eat it when they have a bountiful supply, and as they chew they meditate, and as they meditate they chew, and their better natures predominate under the soothing influence of the weed, and in memory they turn back to thoughts of brighter and happier days.

The boat was now heading for the south end of the island, where I proposed to make a landing on a large black rock that projected well out of the water. Taking out of my pocket a paper of tobacco and opening it, I offered it to the guard, and at the same time resolved, that should he partake of it, I would cast the remainder of the paper to the prisoners and tell them to keep it. To my intense satisfaction the guard helped himself to all that he wanted, and returning it thanked me in a kindly way. As I was receiving it I tipped a wink to the prisoner oarsmen, just to prepare them for what might follow. In an instant the tobacco was at their feet, and both oarsmen reached forth for it. This was my grand opportunity; out went four papers of tobacco from my pocket to where they sat, I at the same time remarking, "There boys, no quarreling!" While all this was happening the guard remained passive. Now was the time to make sure of him, as taking a few cigars in my hand I offered them to him, remarking, "There, Mr. Guard, is your share of the 'plunder,' they will help pass the hours away during your 'off time.'" He accepted them, and thanked me. I now felt that my introduction and good standing was thoroughly established, and that I was free to enter into conversation with the prisoners. I had noticed that whenever the boat came to a stand still, one of the oarsmen took from his pocket a long and black object, in which he was deeply interested, and seemed to be busily working on it. My curiosity being excited, I inquired of the guard what he was doing, and was surprised to learn that it was a horse-hair watch guard. Becoming still more interested, I asked permission to examine it, and could not help expressing my admiration, for it was a very unique piece of workmanship, and I wondered the more, as I glanced at his heavy and coarse hands, and calloused fingers, that he could handle the fine horse-hairs with such exquisite skill. Every strand was perfect, and the gradual swelling of the guard from its two small ends to its centre was all that could be desired.

Seeing that the watch-guard was nearly finished, I inquired of him the price, and was informed that it was three dollars, and that it took some two months to

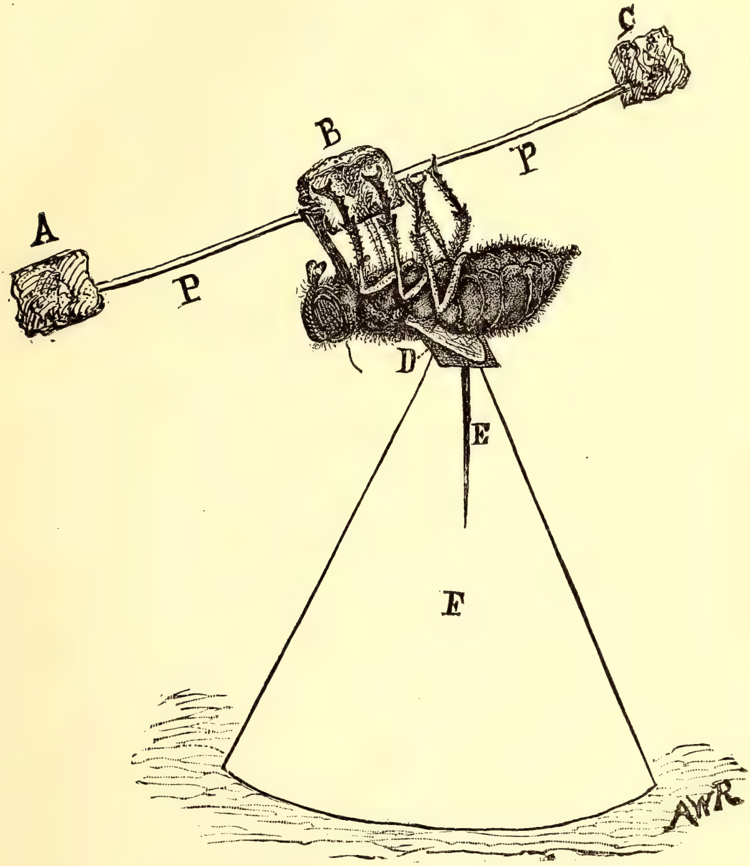
make one, under favorable circumstances. The "favorable circumstances," I imagined, meant the leniency of the river guard and the kindness of the keeper. I would have purchased the one on which he was at work but was informed that he had already sold it. I inquired how he obtained the horse hairs with which to make the guards, and he informed me that friends visiting him always brought a good supply. "Imagining your present occupation and manner of passing away time in your cell was to fail you, what would you do then?" I inquired. "Well, I'd fall back on my performing flies; you see we must have something to occupy our minds, to put a stop to the everlasting recollections of days gone by, and the mistakes and blunders we have made, or otherwise one-half of us would go stark mad. Oh yes; I have passed away many hours in my cell harnessing up and training my performing flies." "Excuse me, but I don't understand what you mean by performing flies," I replied. "Why, didn't you ever hear of or see flies perform with a balancing pole? of course they have to be kind of fixed up or harnessed up, or else they'd be very 'fly'" "No, I confess I have not; it's all new to me; explain how it is done." "Come, now, I'll do better than that; you seem to have plenty of coin, and we exiles are always short on it; I'll sell you my best performing blue-bottle fly and a pure blonde at that, for two dollars, harness and all thrown in. I've had him now for three weeks, and he is sound as a dollar. I'll have him ready for you when you come to the island after more of those enemies!" (I never knew a fisherman, and but very few of the ordinary run of people that I have met, for whom the word anemones was not a little too much. It is always enemies or animies). "All right, it's a bargain. Here, Mr. Guard, you hold the money, then I will be sure that you will not break your promise."

By this time we had reached the black rock, but not an anemone was to be seen. After a general overhauling of the water wall on the east side of the island, I discovered a large number of anemones some eight or ten feet below the surface, but they were well out of reach and almost out of sight; even the guard could not detect them, but to my practiced eye they were quite visible. By this time the tide had become so high that I concluded to abandon all further search for that day. Having obtained from the guard his name and time for going on post next day, I went *home*, not back to the Aquarium. Oh no, I wouldn't do that, not if I had to stay out for a week. What, go back to the Aquarium without anemones? No sir. I mailed a postal card, stating that I had found the anemones, but was having some difficulty in capturing them. That night I made what is known as a "scraper." With one of these scrapers you can peel an anemone from any dock spile or smooth rock, no matter how fast it holds on. All Tuesday morning I was as restless and uneasy, well—as a "fish out of water," so anxious was I to be on my collecting ground. At last I reached the island, and felt happy and jovial when I found myself once more in the guard boat with my new friends. They looked curiously at the scraper, with its mosquito net bag and long, slender handle, and I looked just as curiously at them for some indication of a harnessed-up performing fly.

"Now, Mr. Guard, please take me to the same place, where I discovered the anemones yesterday."

The reader must understand that this part of the island was a retired spot, well out of sight, and I argued that it would be just the place for a private fly performance. Well, to cut this narrative short, after much trouble I obtained a goodly showing of anemones. Now for the fly part of it. The accompanying figure shows exactly how the blonde-headed blue-bottle was "harnessed up," as my prison friend termed it. The performer was a well-fed medium sized ordinary blue-bottle fly with the exception of his head which was of a light yellowish brown color, in fact a pure blonde. To the upper side of his wings a piece of writing paper had been either glued or gummed; after the gum or glue had become dry, and the fly's wings were securely fastened to the paper, the wings and paper had been cut

away to within an eighth of an inch of where the wing joins on to the body of the fly as shown at D in the figure. Through the piece of paper on which the fly's wings were fastened, a long and slender pin passed, as shown at E. This pin entered the apex of the paper cone, F, on which it rested. A thin broom splint from one and three-quarter inches to two inches placed on his legs, which he immediately grasped with his six feet. At times he would spin it around with great rapidity, again he would pass forwards and backwards from one end cork to the other, or he would hold it in a perpendicular position by one of the end corks. Sometimes he would allow one end of the pole to rest on the ground and against the side of the



PERFORMING FLY.

in length, constituted the balancing pole P P. This pole was sharpened to a fine point at both ends, so that it might be passed into the three small pieces of cork, A B C. Now I will try and describe the performance. When the fly was placed in position on the apex of the cone, E, as shown in the figure, the balancing pole was cone, while the other end he retained with his feet; suddenly he would raise the pole and spin it around. When releasing the fly for exercise, and that he might clean himself or have a sun bath, the pin is withdrawn from the paper, or the fly is immersed for an instant in water which soon softens the gum and the fly is free.

THE

Young Scientist.

A Practical Journal for Amateurs.

(With which is incorporated "The Technologist," "The Industrial Monthly," and "Home Arts.")

PUBLISHED MONTHLY AT $1.00 *PER YEAR.*

EDITORS.

FRED. T. HODGSON. JOHN PHIN.

Published by

THE INDUSTRIAL PUBLICATION CO.,
49 Maiden Lane, New York.

Our New Departure.

WITH this number the Young Scientist enters upon its SIXTH volume. At the time the first number was issued there was no journal of the kind in existence, and to-day there is not one that covers the same field that we do—a statement which can be truly made of no other journal of which we have any knowledge. The Young Scientist was, therefore, an experiment, and one for which no great success was predicted. Flashy and sensational literature had taken such a strong hold upon the minds of the young, that most of our friends felt that a paper for youth, without "stories," never could succeed. In this, however, they were mistaken, and the present number of the Young Scientist proves it. But, as we have said, the undertaking was an experiment, and its success somewhat doubtful. We were therefore obliged to feel our way, and the Young Scientist has been very far from coming up to our ideal of what such a paper should be. To-day, however, we feel encouraged to take a long step in advance. We have, therefore, nearly trebled the size of the paper; we have provided an amount of important, interesting and necessary illustrations, such as is to be found in no paper which does not use cuts furnished by advertisers, and we have made such permanent arrangements as will not only keep the journal up to the high standard which we have marked for it, but it will secure perfect regularity and promptness.

The principal feature in these arrangements is the addition to our staff of Mr. Fred. T. Hodgson, with whose work all the readers of the Young Scientist are already familiar. His name now appears as editor, in association with my own, and as he will devote his efforts primarily to the Young Scientist, our readers may feel reasonably assured that they have been positively guaranteed against disappointment.

While we hope to made the Young Scientist better and better with each issue, we think we may safely promise that the present number is a fair specimen of what the succeeding numbers for the year will be, with, perhaps, the single exception of the tint inset, a feature which will not appear in every number. But the reader will observe that we have enlarged and strengthened all the old departments, and added several new ones. Our old contributors too have come forward with their best efforts, and Professor Berlin H. Wright, who is deservedly such a favorite with our astronomical readers, begins a series which will continue through the year. But the wider range of subjects which we now include, demands new laborers, of whom we have secured several. We therefore feel certain that every intelligent boy and girl will find matters of permanent interest and value in our pages.

Such extensive improvements, of course, involve greatly increased expenses. The truth is, that our expenses are more than treble, and therefore, we find it imperatively necessary to increase the amount of the yearly subscription. But as we expect a very large accession to the list of our readers, we do not feel obliged to increase the price in the same ratio as the expenditure, and therefore we have fixed the subscription at the even dollar, a sum which is easily sent by mail.

We have long been urged to this step by a very large number of our subscribers, and now we rely upon them to aid us in carrying it out. To those who feel willing to expend a little effort in obtaining new subscribers, simply for the sake of advancing a good cause, we offer the greatly improved journal which such assistance will enable us to give them, while to those who feel that they cannot labor except for a more substantial reward, we offer the very liberal list of premiums which will be found in our advertising pages.

J. P.

Those who have sent in their subscriptions for the Young Scientist for 1883 at the old rates, prior to the issue of this number, will receive all the issues for next year without further charge. So that no dissatisfaction on their part can possibly arise on account of an increase in price of the Journal.

Many boys in Philadelphia have learned to work sheet brass into *repousse*, or raised figure work. Picture frames, shields, medallions, and many other works may be formed by this process, and the art is readily acquired. Many of the boys, who are making a study of the art, are able to earn enough from the results of their labors to pay their expenses while learning. This work is not confined altogether to boys, as many young ladies in the Quaker City have learned the art, and have turned out some very creditable specimens of workmanship.

While confined within the limits of a fifty-cent journal we found it difficult to devote to *interchange* of information as much space and time as we could have wished, and therefore our column of notes and queries became somewhat spasmodic. We now commence a new series with the inquiries which have accumulated during the past few months, and begin with a new series of numbers. Hereafter, all references to answers or inquiries, subsequent to January, 1883, should be by number, and by the *number of this series.* We might also add that we hope our readers, in replying to these queries, will give us the results of their *own* experience, and not merely copy an answer out of some book of recipes. We have all the books of recipes that have been published, and therefore could easily copy such answers ourselves if they were worth copying, which is rarely the case.

Few things fill the heart of an affectionate mother with greater pleasure than to be able to say to her friends and visitors that her Mary or her William made with her or his own hands, this or that little piece of work. Who has not seen a mother's face illumined with justifiable pride when exhibiting to others some piece of fancy needle-work, shell-work, painting, or other specimens of her daughter's artistic skill; and when she is able to point out a cabinet, basket, chair, clock, shelf or any other useful or ornamental article, made by the hands of her boy, her pride is visible in every movement. Now, there is no boy or girl among our many thousands of readers, that is not able to make or work something that will tend to make home more joyous, and at the same time fill their mother's heart with pleasure. Of course it is quite necessary that parents should aid their children to develop their artistic and constructive talents by furnishing them with the instruments, tools, and materials necessary; and by giving them proper encouragement. Many a boy has been saved from pernicious habits and certain destruction by knowing how to use tools.

The singular article by Mr. Roberts, entitled "Prisoner's Pastimes," can hardly fail to attract wide attention. It will call to mind the stories told of famous state prisoners, who, to save themselves from madness, tamed rats, mice, and even spiders. But it teaches a lesson deeper than the mere fact that ordinary men must have something to do to keep the mind from "wearing out its scabbard." We doubt if expert professional criminals ever give their time to such pursuits. It is more probable that they spend their

leisure moments in devising new schemes for plunder, or, as the poet says—

"E'en in penance planning sins anew."

But when the ordinary prisoner, who has not adopted crime as a "profession," leaves the jail, he finds that the work which occupied his mind there is no longer of any use to him, and therefore he is obliged to fall back upon crime in order to maintain his existence. All this points to the great lesson that every man should be taught some useful trade or profession, and that every boy should be encouraged to use his hands as well as his head. Our prison statistics show that very few criminals ever learned a trade. Indeed, a good trade may be said to be the great preventive of crime, and if our prisons are to be anything more than mere houses of punishment, if they are to be made in any sense reformatories, they must become some great trade-teaching schools.

We make no apology for bringing these truths to the notice of our boys. The boys of to-day will be the rulers of to-morrow, and it is necessary that they should be imbued with clear and sound ideas on all these points, and not be at the mercy of demagogues and politicians. It is not the province of the YOUNG SCIENTIST to teach political economy, but when this department of science touches subjects with which we have to do, it would be wrong to ignore it.

One of the greatest difficulties that besets the path of the amateur mechanic is the care and attention demanded by his tools. When a new tool is obtained in good working order, the young amateur is apt to think it should continue to remain in that condition for an unlimited period. We frequently find the first work executed after a new supply of tools has been received, to be of a better quality and finer finish than subsequent productions. It will puzzle many to understand why this is so; but if the tools of the operator should be examined, and compared with the condition they were in when first used, the mystery will vanish, as the tools will be found blunt, out of shape, and perhaps full of small breaks. The "soles," or bottoms of the planes—if of wood—will be found out of truth, twisted, sprung, or hollow transversely; the saws dull, or, if an attempt has been made to file them, the teeth are unequal in length, irregular in size, and filed to all kinds of angles and shapes; the oil-stone will be clogged up with oil and dirt, and the squares, chisels, gauges, and other tools will be found scattered about the workshop or bench in beautiful confusion. The most expert workman can not make good work with tools out of order; he may make good work with inferior tools, as his skill as a workman will enable him to put them in order for the occasion. How difficult, and how discouraging, then, must it be for the young amateur to make fair work, with tools in bad order? Three-fourths of the discouragements that take place in amateur work are the results of using inferior tools, or tools out of order; and we propose to aid the young—and old—amateurs, through the columns of the YOUNG SCIENTIST, to overcome these difficulties, by giving them reliabie information regarding the care of tools, and also of the kind and quality of tools most suitable for their purposes. To accomplish this we have secured the services of a person whose knowledge of the use of tools is very extensive, and who, under the incognito of "Our Ned," will monthly discuss these matters in our columns in a way that may be easily followed by our youthful readers.

Among the Stars.

JANUARY, 1883.

(All Computations are for the Latitude and Meridian of New York City.)

Mercury is brightest as an evening star January 19-22, being at greatest angular distance (18° 32'), east of the Sun on the 22d. He is situated in the 20th degree of Capricornus, 20° S.W. of the λ of Aquarius. The bright star, Fomalhaut, in the Southern Fish, which is further south and sets 19 m. later, will not be as bright. Mercury sets:

	D.	*H. M.*		*H. M.*	
Jan.	15	6 17	eve.	1 19	after sunset.
"	20	6 32	"	1 28	" "
"	25	6 35	"	1 25	" "

in each case 6° 13' north of the sunset point.

Venus has passed to the west of the Sun, becoming a morning star, and 34 days after her transit, or Jan. 9, arrives at greatest brilliancy. She is moving eastward past the stars of the constellation Scorpio, being, at the beginning of the month, only about 10° north of the red star, Antares, and on the last of the month, near the end of the handle of the Milk-maid's Dipper. Venus' phase is a large crescent. She rises on the 10th at 4h. 21m. A.M.; 20th, 4h. 11m. A.M.; and 30th at 4h. 9m. A.M.

Another Transit of Venus will not occur until June, 1996, 114 years hence. The present generation of astronomers must, therefore, be content with the results of the one of last December. Only five transits of Venus have ever occurred of which we have any record; they are as follows: December, 1639; June, 1761; June, 1769; December, 1874; December, 1882.

In 1629 Kepler predicted a transit which occurred in 1631, but it was not seen. He also predicted that of 1761, but he never had the pleasure of seeing his predictions verified; he died only a few days before that of 1631 occurred. From the transit of 1761 a solar parallax of 8″.73 was deduced, which corresponds to a distance of 94,279,932 miles from the Earth to the Sun. The transit of 1874 gave, as a mean of several results, a parallax of 8″.82, corresponding to a distance of 83,492,526 miles. The former transit occurred near the time of the Earth's aphelion, and the latter near its perihelion. Allowing 3,000,000 miles as the difference between greatest and least distances, the distance has been reduced by about 8,000,000 miles. The results of the '74 transit must be nearly correct (a variation in the solar parallax, when placed at 8″.8, of 0″.01 makes a difference of 104,362 miles), and as the results of each successive transit depend upon the computations of the preceding ones, it is quite certain that the transit of last month will give a very close approximation to the truth. It will be several months before the final results will be known.

Mars was in conjunction with the sun Dec. 10, and is now a morning star, but will scarcely be seen this month, rising only one hour before the Sun on the 25th. His satellites will not be seen at all this year, even by the aid of the most powerful telescopes known.

Jupiter was brightest on the 18th of last month, and will be the most brilliant object in the evening skies for many weeks. He is in the eastern part of the constellation Taurus, upon the west margin of the Milky-way, and midway between the two stars *Beta* Aurigæ (2d mag.) and *Zeta* Tauri (3d mag.), which are supposed to mark the tips of the Bull's horns. He is situated in a glorious portion of the Heavens. Just 30° west of him is the large V-shaped figure in the Bull's head known as the Hyades, of which the splendid red double star, Aldebaran, is the lucida. Near by is the Pleiad group or "Seven-stars" (a misnomer, as 12 stars have been seen in this group, and charted, with the unassisted eye, and 499 have been charted, down to the 14th magnitude). Capella and the beautiful little triangle called the "Kids" are north, and Betelguese about the same distance south of him. Orion with its grand array of magnificent objects, is below or south of Jupiter, and Procyon and Gemini east of him.

The celebrated "Crab Nebula" is about 1° south of him on the 26th, which position will be practically retained for several days before and after that date. This will be a good time to look for that interesting object which may be seen with small telescopes. This is the Nebula which the Earl of Rosse resolved into stars with his 6-feet reflector. It looks more like a vast pineapple than a crab, however, with its branches clustering with gems and gold.

JUPITER'S SATELLITES.

The following are the eclipses of Jupiter's Moons which are visible at seasonable hours:

		D.	*H.*	*M.*		
Satellite	II.	1	7	16	even'g.—	Reappearance.
"	I.	2	11	0	"	"
"	III.	4	6	48	"	"
"	II.	8	9	52	"	"
"	I.	11	7	24	"	"
"	III.	11	10	50	"	"
"	I.	18	9	19	"	"

Jupiter's shadow is now projected west of him, but so slightly that the satellites pass from occultations into eclipses without becoming visible, hence the beginning of the eclipses and end of the occultations cannot be seen, transpiring, as they do, *behind* the planet, and the satellites suddenly become visible some little distance west or to the right of the planet.

The early-evening occultations begin as follows:

Occultations.				*Transits.*				
Sat.	*D.*	*H.*	*M.*	Sat.	*D.*	*H.*	*M.*	
I.	2	8	22	I.	3	5	41	ingress.
II.	8	6	5	I.	3	7	56	egress.
I.	9	10	7	I.	10	7	25	ingress.
III.	11	5	44	I.	10	10	16	egress.
II.	15	8	21	II.	24	7	41	egress.
I.	18	6	19	I.	26	7	40	egress.
II.	22	10	40	II.	31	7	19	ingress.
I.	25	8	7	II.	31	10	4	egress.

The transits occurring when the satellites are in the nearer portions of their orbits must occur from left to right, and the shadows *follow* the satellites; the *shadow* of I. beginning its transit 22m., II. 50m.. and III. 1h. 54m. after the respective satellites begin theirs. Jupiter passes the

meridian as follows: 10–10 10 eve.; 20—9 26 eve.; 30—8 44 eve.

Saturn is further west or higher up, and only a few degrees west of the Pleiades. His rings are not seen so well as in August and September, but they are still very fine objects requiring only a very small telescope. We always take a look at him if in sight before leaving the observatory.

Penn Yan, Yates Co., N. Y.

Polishing Metals.

Soft metals, like gold and silver, may be polished with comparatively soft powders, such as prepared chalk or putty powder (oxide of tin). When metals are to be polished in the lathe the process is very simple. After being turned or filed smooth, the article is still further polished by means of fine emery and oil, applied with a stick, and in the case of rods or cylinders, a sort of clamp is used so that great pressure can be brought to bear on the part to be polished. The work must be examined from time to time, to see that all parts are brought up equally to the greatest smoothness and freedom from scratches, and as fast as this occurs, polishing powder of finer and finer quality is used, until the required finish is attained. In polishing metals or any other hard substances by abrasion, the great point is to bring the whole surface up equally.

A single scratch will destroy the appearance of the finest work, and it cannot be removed except by going back to the stage to which it corresponds, and beginning again from that point. Thus, if in working with a smooth file, we make a scratch as deep as the cut of a bastard file, it is of no use to try and remove this scratch with the smooth file: we must go back, and taking a bastard file, make the surface as even as possible with it, and afterwards work forward through fine files and polishing powders.

Baked Angle Worms.

The *Pall Mall Gazette* (London) gravely reports that a group of French gourmets have tested the edible qualities of the common earth worm, whose agricultural services have been so recently demonstrated.

"Fifty guests were present at the experiment. The worms, apparently lob-worms, were first put into vinegar, by which process they were made to disgorge the famous vegetable mould about which we have recently heard so much. They were then rolled in batter and put into an oven, where they acquired a delightful golden tint, and, we are assured, a most appetizing smell. After the first plateful the fifty guests rose like one man and asked for more. Could anything be more convincing? Those who love snails, they add, will abandon them forever in favor of worms."

Leaf and Fern Natural Prints.

The new process of photographing, known as the "blue process," described in a previous number of this journal, has given rise to a very interesting amateur art—the photographing of leaves and ferns. Fibrous leaves, like those of the maple, oak, poplar, birch, make the best photographs. Hairy, rough, or velvety specimens never prove satisfactory, nor do those that are immature, imperfect, succulent, or have a thick, leathery epidermis. None are better adapted for the experiments of the beginner than fern fronds. After the leaves or ferns have been collected, press and dry them very carefully, for which purpose a botanical press, if judiciously used, is the most satisfactory. Great care is required, lest by too heavy pressure the tender and delicate foliage and finer sprays become crushed, and thus spoiled for printing. Old books and files of newspapers will be found to answer well for the herbarium.

The requisites for leaf printing are neither numerous nor expensive, consisting of two panes of window glass free from bubbles and other defects, and sheets of prepared paper which may now be obtained from any dealer in artists' materials, though if the reader should desire

to make it himself he can easily do so by following the directions previously given.

To make the print, place on one of the panes of glass several folds of tissue paper, and upon these the dried sensitized paper, with the prepared side uppermost. Upon this arrange the leaf or fern, singly or in a group, lay over it the second pane of glass, and secure the whole together with four clips, one at each corner. Place the arranged glasses in the clear sunlight in a secure place, where the fresh air can blow over them. If the day be clear, in about thirty minutes, more or less, the figures will be printed. Watching the paper during the process, you will observe the uncovered parts gradually changing from a yellowish tint to a vivid blue color, the latter deepening into black. When sufficiently tinted, remove the top glass and raise the leaf, when you will find a yellow outline on a deep blue ground. Now wash the paper in several clear waters until the yellow tint bleaches to a clear white; dry with blotting paper, and place under a press. If the glass is removed too soon, the printed picture will be pale and washy in appearance; if exposed to the sunlight too long, the ground will be light, instead of a deep, dark color. Experience alone will teach the proper time of exposure. The printed leaves or ferns ought to be mounted on the left page of an album, writing on the opposite page the common and botanical name, description, habitat, and, indeed, whatever appears interesting in connection with the specimen.

Hard Woods.

Chestnut and butternut are not very extensively sold for finishing, for which the better grades are selected, and their sale is dependent more on the question of taste than real superiority. The poorer stuff is used in common ways, and is best worked off when other woods used in manufacture are scarce in the dry, and the cull's stocks can be employed as a substitute on a pinch.

Basswood is considerably sold for use in furniture.

The black or red birch, which largely resembles cherry, figures somewhat as a finishing wood. The yellow is not valuable in the same way.

Beech enters into the manufacture of chairs, tool handles, brewers' shavings, etc.

Elm is made into cheap furniture.

Yellow pine is very slow in gaining a hold upon popular favor. It is used by a great many operators who speak highly of the lumber, but it is far from having a boom. Generally buyers do not take to it kindly. What is used is mainly for flooring and finishing. Though the boards and planks are a subject of considerable complaint on account of imperfection in manufacture, the flooring is conceded to be turned out in good shape. Where high grade flooring is wanted, yellow pine is regarded the best and cheapest, but where a low or medium grade is desired the wood must give way to white pine. The latter is sold much cheaper than the yellow pine, for when freights are added to the price of the lower grades the yellow pine can hardly compete.—*N. W. Lumberman.*

Scientific News.

— Scientific men in Japan are now discussing the possibility of utilizing the internal heat of the earth. At a recent meeting of the Seismological Society, Mr. Milne read a paper in which he said that the fact that there was an unlimited supply of energy in the interior of the earth had been generally overlooked, although portions of it crop out in countries like Japan, Iceland and New Zealand, in the form of hot springs, solfataras, volcanos, etc. He stated that there is an unlimited supply of water in hot springs within a radius of 100 miles around Tokio, and that the heat of these springs could be converted into an electric current and transmitted to the town.

— The amount of water which passes through the roots of a plant is enormous. Dr. Lawes, of England, has found that an average of 2,000 pounds of water is absorbed by a plant for every pound of mineral matter assimillated by it. At the French Agricultural Observatory at Montsouris it was found that 7,702 pounds of water passed through the roots of the wheat crop for 10¼ pounds of grain produced, or 727 pounds for each pound of grain, in rich soil; while in a very poor soil 1,616 pounds were passed through the same quantity of wheat for a product of about half a pound of grain, or 2,693 pounds of water for each pound of grain.

— An experiment which belongs to the curiosities of science was made quite recently at Paris by Drs. Regnard and Blanchard on a stud of ten live crocodiles which had been presented to M. Paul Bert, late Minister of Public Instruction in France. A crocodile was fixed on a table, and its upper jaw was connected to an overhead dynamometer or powermeter by means of a rope. By startling the animal with an electric current the downward blow of the jaw was measured, and found to be 308 pounds at the point, which, considering the distance of this point from the masseter muscle causing the movement, made the total contractile force of the muscle itself equivalent to 1,540 pounds. This extraordinary snapping power was that of a Saigon crocodile weighing only 120 pounds. An ordinary

sporting dog gave a snap of 72 pounds at the muzzle, corresponding to a contractile force in the muscle of 360 pounds.

— Ordinary vulcanized caoutchouc should contain about 1-10 to 1-6 of sulphur, a greater proportion yielding a hard, horn-like product, which expands considerably when heated. It was established by Mr. Kohlrausch, some years ago, that this hard caoutchouc, while expanding equally with mercury up to the freezing point, expands much more at higher temperatures; so that in a thermometer consisting of a vessel of this material filled with mercury, the latter would appear to contract with an increase of temperature. Results of experiments made by Mr. R. Fuess, of Berlin, appear to confirm Professor Kohlrausch's statement. Mr. Fuess placed a rod of caoutchouc, 1-5 inch thick, in a glass tube, 3-5 inch diameter, and filled the tube with mercury to a height of 3 feet, exactly up to a little pin of platinum projecting horizonitally from the caoutchouc. The calculations from fifteen observations, in which he was assisted by Dr. M. Tiessen, gave an expansion co-efficient of .000082 for each degree C. up to a temperature of 65° F.; higher figures resulting from observations at higher temperatures.

Current Notes.

— A medical man, struck with the large number of boys under fifteen years of age he observed smoking, was led to inquire into the effect the habit had upon the general health. He took for his purpose thirty-eight, aged from nine to fifteen, and carefully examined them. In twenty-seven he discovered injurious traces of the habit; in twenty-two there were various disorders of the circulation and digestion, palpitation of the heart, and a more or less taste for strong drink. In twelve there were frequent bleedings of the nose, ten had disturbed sleep, and twelve had slight ulceration of the mucous membrane of the mouth, which disappeared on ceasing the use of tobacco for some days.

— Without doubt the largest kite in the world was lately made by Dr. Beebee, near Rochester, N. Y. According to the Rochester Express, the frame was made of lumber 2 inches wide by ½ inch thick, and was covered with manilla paper. The surface contained nearly 250 square feet. The string by which the kite was flown was a coil of ⅜-inch rope, ordered from Rochester, and was nearly 5,000 feet in length. To the astonishment of hundreds of spectators, it shot into the air like a balloon. After the monster had floated a mile high for a couple of hours the problem of getting it down was next in order, and was not accomplished until a pulley and team was brought and hauled it down.

— Among the newest Christmas cards are tablets of ivory upon which mottos and quaint pictures are painted. A tiny scent bottle not more than an inch and a half in length, is a novelty. It is made half of thick glass and half of silver; the silver portion screws on over a small glass stopper. It is intended to slip in the inside of the glove, and is made very smooth for that purpose. A heavy piled plush is stamped with a pug's head. It is in a shade corresponding to the background, so that the dog's head, which is clearly defined, seems to be peeping out of a soft warm nest. Many ladies suffering from the antique fever are dipping their costy laces in coffee to give the desired "yellowed with age" look.

— Mr. Dardenne's self-winding clock may be considered to have had a fair trial. A specimen clock was fixed at the Gare du Nord terminus, Brussels, last September, due precaution being taken to avoid tampering with it by affixing the Government seal. After six months' trial it was found in perfect time with the Observatory clock. The clock is wound by a small anemometer or windmill, which is, by a reversed train of multiplying wheels, continually drawing over each wheel an endless chain, in one loop of which the clock weight is supported. As the loop hangs between the clock and the winding machine, the weight is continually drawing through the clock the slack chain drawn up by the wind motor, and thus a constant motion is maintained. A ratchet wheel prevents the motion from turning the wrong way, and whenever the weight is wound right up to the top the motion is checked by a friction brake automatically applied to the anemometer by the raised weight lifting a lever. When the weight is fully raised the clock has a sufficient store of energy to go for twenty-four hours.

— Dr. Franklin invented a stove in 1745. Previous to that time there were stoves in Holland and Germany. Franklin's stove, however, was a great improvement on all that had preceded it. In 1771 he invented several other stoves, one for burning bituminous coal, which would consume its own smoke and had a downward draught, and another intended for the same purpose, having a basket grate or cage, with movable bars at the top and bottom, supported by pivots at the centre, and which, after being filled and kindled at the top, could be inverted, and so made to burn from the base. The next inventor of stoves, ovens, and heating and cooking apparatus, was Count Rumford, who, between 1785 and 1795, devised several improvements, all intended to economize fuel and heat. It may be stated that the box stove now in the State House at Richmond, Virginia, bears date of 1770, is one of the so-called Holland stoves, and was probably imported from England, as the castings, though rude, are superior to the American castings of that day. For cooking purposes Count Rumford's cooking stoves or ranges, lined with fire-brick or soapstone, and with a ventilating oven, which had been introduced into New York as early as 1798, and into Boston about 1800, were gradually coming into use, and between that time and 1825 there

was, considering the period and the obstacles, considerable activity in this branch of manufactures, which has been increasing ever since.

Practical Hints.

— When color on a fabric has been accidentally or otherwise destroyed by acid, ammonia is applied to neutralize the same, after which an application of chloroform will, in many cases, restore the original color. The application of ammonia is common, but that of chloroform is but little known.

Oil Polish for Dining Tables.—One quart of linseed oil to be simmered (not boiled) for ten minutes and strained through flannel; then add an eighteenth part of spirits of turpentine; to be applied daily with a soft linen rag, and wiped off lightly. The only polish that will resist hot dishes.

Bronzing Liquid.—Ten parts of aniline red and five parts of aniline purple are dissolved in 100 parts of 95 per cent alcohol, on the water-bath, and the solution, after the addition of five parts of benzoic acid, boiled (for 5-10 minutes) until it has changed its greenish color to light bronze-brown. Applied with a brush upon leather, metal or wood, the liquid produces a magnificent bronze coating.

Glueing.—French cabinet-makers use a glue-pot with an inside pan made of glazed earthenware and divided radially into three divisions, in one of which is kept strong glue, in another weaker, and in the third water only, with a brush or piece of sponge, for cleaning off superfluous glue from the work. Chalking the joints in glueing end-wood is not to be recommended; a better plan is to size the end-grain with thin glue first, and then make a smooth face before glueing permanently.

Hardening Steel.—For hardening thin steel articles Dr. Hartman recommends: 4¾ qts. of train oil, 2 lbs. of beef tallow, ¼ lb. of beeswax, and 1 lb. of resin. The exact amount of resin, however, is a matter of experiment, always bearing in mind that the greater the proportion of resin the higher the temper. Another mixture recommended on the same authority, is 95 qts. of spermaceti oil, 20 lbs. of tallow, 4½ qts. of neatsfoot oil, 1 lb. of pitch, and 3 lbs. of resin. The pitch and resin are melted, the other ingredients added, and the whole heated until it will ignite if a blaze is brought in contact with it, when it is covered and allowed to cool.

— In the *Polytechnisches Notizblatt*, M. Tilhet's method of copying drawings in any color that may be required or desired is thus described: "The paper on which the copy is to appear is first dipped in a bath consisting of 30 parts of white soap, 30 parts of alum, 40 parts of good glue, 10 parts of albumen, 2 parts of glacial acetic acid, 10 parts of alcohol of 60°, and 500 parts of water. It is afterwards put into a second bath, which contains 50 parts of burnt umber ground in alcohol, 20 parts of lampblack, 10 parts of good glue, and 10 parts of bichromate of potash in 500 parts of water. They are now sensitive to light, and must therefore be preserved in the dark. In preparing paper to make the positive print, another bath is made just like the first one, except that lampblack is substituted for the burnt umber. To obtain colored positives, the black is replaced by some red, blue, or other pigment. In making the copy, the drawing to be copied is put into a photographic printing-frame, and the negative paper laid on it, and then exposed in the usual manner, In clear weather an illumination of two minutes will suffice. After the exposure, the negative is put in water to develop it, and the drawing will appear in white on a dark ground; in other words, it is a negative or reversed picture. The paper is then dried, and a positive made from it by placing it on the glass of a printing-frame, and laying the positive paper upon it, and exposing as before. After placing the frame in the sun for two minutes, the positive is taken out and put in water. The black dissolves off without the necessity of moving it backwards and forwards."

Our Book Table.

The Builder's Guide and Estimator's Price Book. Being a compilation of Current Prices of Lumber, Hardware, Glass, Plumbers' Supplies, Paints, Slates, Stones, Limes, Cements, Bricks, Tin, and other Building Materials; also, Prices of Labor, and Cost of Performing the Several Kinds of Work required in Building; together with Prices of Doors, Frames, Sashes, Stairs, Mouldings, Newels, and other Machine Work. To which is appended a large number of Building Rules, Data, Tables and Useful Memoranda, with a Glossary of Architectural and Building Terms. By Fred. T. Hodgson, Editor of "The Builder and Wood-Worker"; Author of "The Carpenter's Steel Square, and its Uses," Etc., Etc. 1 vol., 12mo., cloth, gilt. Price, Two Dollars. New York: The Industrial Publication Company.

The scope and character of this work are so fully set forth in the title that nothing need be said as to its contents; they speak for themselves, and at once commend the volume to those who are seeking for the information which it contains. But as regards the execution of the book a word or two may not be out of place.

The value of a volume of this kind will depend upon three things: First, the need which exists for such a book; secondly, the good judgment that is exercised in selecting the information that is given; and thirdly, the fidelity and care with which the work is done.

As regards the need for such a book there can be no question. Every architect, contractor, builder, and even every country carpenter, feels the need of just such a book as that before us. Several attempts have been made to supply the

want, but they are all very defective, and although the present volume may not be perfect it is certainly a great advance over any of its predecessors. That it contains just the information that is needed by those for whom it is intended, is guaranteed by the well known reputation of the author, who has not only had extensive practical experience in the matters to which the work relates, but has, through his position as editor of the *Builder and Wood-Worker*, been brought into intimate contact with the very persons to whom the work addresses itself.

Bearing these facts in mind, we have gone carefully over its pages and tested by actual calculation, many of the rules and results given. In every case we have found them correct, thus proving the painstaking fidelity of the author. A work of this kind, to be of any value must be above suspicion as to the accuracy of its contents, and from the careful examination which we have given it, we believe that the present volume is as nearly correct as it is possible to make such a book.

The work forms a handsome volume of nearly 350 closely printed pages, and we feel confident that it will find its way into the library of every one who is practically interested in the art of building—not only professional men, but intelligent house owners who desire to check the estimates handed in by builders and others. J. P.

Hints on Estimating. Chas. D. Lakey, Publisher, New York. Price, nine cents in stamps.

To the amateur who wishes to build a barn, fence, stable or workshop, this little treatise will be of great service, as from it he can find out the cost of the structure before he commences work. To the regular carpenter or joiner, it will prove an invaluable aid in assisting him to arrive at the costs of the various works he may be called upon to erect or value.

The Metal Turner's Handbook. By Paul N. Hasluck. Published by Crosby, Lockwood & Co., London, Eng.

This is a little work of some 150 pages, divided into fifteen chapters, two only of which may be said to be of any real service to the amateur metal worker—i.e., the one on the slide-rest, tools and cutter-bars, and the chapter on tool grinding, and even these are more descriptive of appliances than of the manner of operation. The remaining thirteen chapters are devoted more particularly to descriptions of the various makes of English foot-lathes, slide-rests, and lathe tools of several kinds, and one chapter is devoted altogether to the dimensions of small motors. Indeed, from our point of view, the work partakes largely of a manufacturer's descriptive circular, or rather of a number of them, bound in one cover, as the one hundred and fifty illustrations contained in the work are evidently taken from makers' catalogues. We do not know that this lessens the value of the work, but we are inclined to think these illustrations and the accompanying descriptions, are not altogether in place in a small book with a title similar to the one before us; or, in other words, the title of the book is misleading; it is the play of Hamlet, with very little of Hamlet left in. Notwithstanding its misleading title, the book possesses merits as a guide in some departments of metal turning, particularly so in the chapter on overhead gearing, and many hints and suggestions are offered regarding the construction and management of these useful additions to the foot lathe. To anyone about to purchase a lathe this book will prove valuable, as it will give the intending purchaser some "points" with regard to the construction and capabilities of different kinds of lathes, that may be of service to him.

Taking it all in all, while we cannot recommend the book to our younger amateurs, we have no hesitation whatever in saying the work will be serviceable to the advanced amateur and all who desire to be well posted on the foot-lathe.

The Builder and Wood-Worker. For Architects, Cabinet-Makers, Stair Builders, Carpenters, Car Builders, etc., etc. Published monthly by Chas. D. Lakey, 176 Broadway, New York.

The December number of this excellent journal is at hand, and as usual, it is full of good things. When we look over its pages and observe the large number of very costly illustrations which it contains, we are astonished to find that the publisher has reduced the price from $1.50 to $1.00, and this is to be accounted for only by the fact that the circulation has increased to an extent very unusual with strictly technical journals. As it now stands it is unquestionably the cheapest journal of its class of which we have any knowledge. Much of this success is due to the fact that the *Builder and Wood-Worker* is of great value not only to professional architects, carpenters and builders, but to every intelligent owner of a house, as its columns afford innumerable hints for improving our dwellings in the direction of convenience, healthfulness and beauty. No house-holder can invest a dollar to better advantage than by subscribing for the *Builder and Wood-Worker*. It will repay its cost ten times over in the practical "wrinkles" which it contains.

Something about Gift-Books.

The holidays are at hand, the days on which congratulations are given and received, and on which are made those little gifts that do so much towards tightening the bonds of affection and love that should always exist between friends and relatives. Among these gifts, books always take a prominent place, and we therefore take this opportunity to give such information on this point as we may collect, so that intending purchasers may be able to choose their books with some idea of what they are to get. We take pleasure, therefore, in submitting the following

notices of holiday gift books, with prices, titles, and remarks:

One of the best books on the list suitable for a boy, is a copy of the new edition of Addison's masterpiece, *Sir Roger De Coverley*, just published by D. Appleton & Co., Bond street, New York. Price, $2.25. The book is handsomely bound and contains 125 illustrations, and has a fine steel etching as a frontispiece.

Another good book, suitable for either boys or girls is the *Magna Charta Stories*, a collection of tales of heroism, edited by Arthur Gilman, A. M. The tales recounted in this volume are presented to their readers with the intention of showing to a certain extent the persistence with which the idea of freedom has been pursued through the centuries, from the mythical age of Horatius to the time of King John, of England. It is not an endeavor to give a history of freedom, but a presentation of the notable instances in the world's history in which men have made their lives memorable in resisting oppression and breaking the bonds of the oppressor. The fact that a number of authors have labored together under the general supervision of the editor, gives the book the advantage of presenting its subject in a variety of lights. While adhering closely to the historical truth, the sketches are all written in a lively, entertaining style. Whether it be merely a coincidence or not, the fact is, that all the papers contributed are, with the exception of the editor's, written by women. Harriet D. Slidell McKenzie, Amanda B. Harris, Mary Blake, Lizzie W. Champney, Susan Coolidge, Mrs. M. E. Sherwood, Anne Laurens Dawes, Mrs. Rose Hawthorne Lathrop, and Mrs. M. H. Catherwood, have contributed the following articles: "The Great Paper," "Horatius at the Bridge," "A Successful Secession," "Two Immortal Names," "At the Toe of the Big Boot," "The Triumph of an Idea," "The Hammer of the Gentiles," "The Barbarian's Overthrow," "The Hammer of the Saracens," "Miltiades at Marathon." "In the German Woods, Long Ago," and "Out of the Dark," are by the editor. A list of authorities is added at the end of each paper, so that the youthful reader can pursue the subject further, if so inclined. This is published by Lathrop & Co., Boston.

A most excellent book for boys between ten and sixteen years of age, is Z. R. Bennett's *A Young Vagabond*, published by J. S. Ogilvie & Co., 31 Rose St., New York. This is just the kind of book boys like to read, and though full of stirring incidents and interesting anecdotes, it does not contain anything that will tend to corrupt their taste or morals, and the illustrations, of which there are a number, are not calculated to vitiate their ideals of life. The work is well bound in cloth and contains 265 pages. Price, $1.00.

A book adapted for the smaller children, boys or girls, is the *New Games for Parlor and Lawn*, by George B. Bartlett, a collection of social games, pleasantly and clearly explained by the author. The charades are so simply arranged that children can easily prepare them for home amusement, and some new changes in old games are suggested. This work is published by the Harper Brothers, New York. Price $1.00.

Another good work for either boys or girls is Dicken's *A Child's History of England.* This is a standard work, and is likely to remain so for all time, and we do not know of any work of the kind we can recommend to our young reader in preference. The American News Co. have issued a fine illustrated edition of this work, covering nearly 500 pages; it is well bound in cloth. Price, $1.25

The fourth part of *Adventures of Two Youths in a Journey to Egypt and the Holy Land*, by Thomas W. Knox, published by Harper Bros., is a seasonable book just adapted for enterprising boys. The author's method of putting the narrative in the mouths of boys is a happy one, and his books are descriptive of countries that had before been neglected by juvenile writers. He has also the art of presenting information so attractively that he has not resisted the temptation to make his volumes very large. The book is illustrated, and contain 438 pages. Price, $3.00.

Two books published by the Scribners' may also be mentioned as making very appropriate gift-books. The one by James Baldwin, *The Story of Siegfried*, is especially adapted for boys, indeed it is the first successful effort to open up to young readers that wonderful world of the Nibelungen Legend, from which they have hitherto been shut out by a lack of the learning that would admit them. They have had either to take feeble versions of the great story, or wait until the time when they could read it understandingly in its fullest form—a time too late to give them the keenest enjoyment of the adventures of Siegfried, the Dragon-Slayer, and the heroes and traitors, giants and dwarfs and monsters, who fought with or against him in that marvellous and almost endless struggle. The work is handsomely illustrated. Price, $2.00.

The other work, *The Ting-a-Ling Tales*, by Frank R. Stockton, will be sure to please the girls both with its illustrations and funny tales. It is full of enchanting sorcery and fairy-pranks, fantastic, grim, preposterous, fanciful, astonishing, quaint, by turns, and always brimful of humor—a peculiarly sly and irresistible humor, of which Mr. Stockton alone has the secret. Price, $1.00.

My Household Pets, by Theophile Gautier, is a desirable gift-book, and will no doubt gladden the hearts of many little ones these coming holidays. Gautier's tender descriptions of his cats—the white and the black "dynasties"—dogs, mice, chameleons, magpies and horses, which owe their charm to his happy style, are sympathetically translated in this neat volume. The work is published by Roberts Bros., Boston. Price, $1.25.

Notes and Queries.

In continuing this department, which has been found of so much value, we would remind our readers who wish for information on any of the arts and sciences, that they are cordially invited to make their wants known through this column, and those of them who can furnish accurate answers to questions asked are requested to send in replies. Doubtless, many of our subscribers may know of methods, processes, or devices that may be better or more suitable for the particular case in question than anything generally known, and it is this reason that induces us to keep this department open for a medium, when an interchange of ideas and practices may be made to the advantage of all our readers. Correspondents will please send their full address when forwarding their communication—either questions or answers—not for publication, unless expressly so stated, but so that we may know where to find the writer if desirable

1. R. G., Newark, N. J.—(1) What is meant by "Cathay" and a "Cycle of Cathay?" (2) Who wrote the "Swiss Family Robinson?"

2. S. N., Hartford, Conn.—I desire to dry and cure some skins, and would like some reliable information on the subject, and if some reader of the YOUNG SCIENTIST will help me I shall feel under obligations?

3. VICTOR, Jersey City, N. J.—Can you inform me what combination of woods is the most suitable for inlaying, where the figures are to be simple and of a kind that an amateur of two years practice can master?

4. NELLIE, Denver.—What materials used, and how applied, for bleaching skeletons and leaves?

5. R. T. Augusta, Me.—I should be pleased to know through this column, why it is that the leaves of trees change their color in autumn?

6 J. N., Philadelphia.—I have heard or read of a table or window fountain that required no outside pressure or "head" other than was contained in the fountain itself and that would play from thirty to forty minutes at a time without recharging. Does any fellow reader know anything of it, and if so, will he kindly give publicity to his knowledge in these columns?

7. REUBEN W., Andover, N. Y.—I am desirous of purchasing a scroll saw, one that will do fine work, and one that may be used for cutting thick stuff—say from one to two inches thick. Now what I want to know is, where can I get such a saw, and can you recommend any firm from whom I can purchase?

NOTE. With regard to the above we may say there are a number of excellent saws in the market, any one of which would answer the purpose sought. We cannot recommend any particular firm to buy from, but we may say that perhaps the saw most suitable for thick and thin stuff is the $20 one manufactured by John & F. Barnes. For very fine work, however, we should prefer the "Lester," or the "Challenge," either of which can be made to do exquisite work when properly handled. We may be able next month to refer you to our advertising pages for reliable firms from whom you can purchase what you want for scroll sawing purposes.

8. "BIG BOY," Utica, N. Y.—I wish to learn amateur carving, will the YOUNG SCIENTIST inform me where I can get any real practical information on the subject?

NOTE.—Books on carving, suitable for amateurs are very scarce, yet there are a few that may be recommended, though they do not, singly, cover sufficient ground to satisfy the wants of a beginner in the art of carving. "Leland's Wood-Carving Manual," price 36 cents, is a very good work and is purely American. General Seaton's "Wood-Carving" is perhaps a better work than "Leland's," as the General himself was an amateur, and wrote his work from an amateur's stand-point. The work is an English one and costs $1.00. There is also another English work by Alfred Rogers, the "Art of Wood-Carving," but it is scarcely obtainable here. Prof. Ben. Pitman, of the Ohio School of Design, Cincinnati, has written a work on wood-carving, which we dare say goes into the subject pretty thoroughly. We have not seen the work as it is scarcely yet in the market. If you write Mr. Pitman as above, he may give you some information regarding it. We intend shortly to begin a series of illustrated articles on the subject in the YOUNG SCIENTIST, in which an endeavor will be made to cover the whole ground of amateur wood-carving. You can learn more, however, by watching some practical workman for a few hours than you can learn from books in a month; and we would advise you to make it a point to visit some place where wood-carving is practiced, so that you may be enabled to see for yourself how the various operations are performed by regular workmen.

9. F. E. F., Lancaster, Pa.—If you will allow me to suggest something which I think would be appreciated by a large number of your readers. I would say that a few illustrations of monograms now and again in the YOUNG SCIENTIST would be quite acceptable. I would like to get a monogram of my initials, for instance, and I am sure there are many readers like me, who would be pleased to get their monograms?

NOTE.—Now, this is just what we want—suggestions—and we hope more of our readers will help us in this way. As regards "monograms," we have already intended to do something in this direction, but did not know exactly how to go about it. Your suggestion has relieved us considerably, and we will now make it a point to illustrate to a limited extent, such monograms as our readers may desire, and we shall be pleased to receive drawings of combinations from our readers who will furnish the same. Remember, that all drawings sent to the YOUNG SCIENTIST must be made in good black ink or pencil, on clean white paper.

10. S. O. G., Savannah, Ga.—I am sometimes puzzled to know what is meant by the word æsthetics; it seems to be used for so many purposes. Will you kindly inform me what the correct definition is?

Market Report.

Price-List of Pet Animals, etc.

All young persons, at some time or other develop a fondness for living pets of some kind. Boys frequently evince a strong liking for ponies, dogs, rabbits, squirrels and similar animals, while the girls delight in caring for little dogs of fine breeds, cats, birds and aquarium fish of all kinds. This trait in young people is a laudable one and worthy of encouragement, as it cultivates a feeling of kindliness and good will towards animals in the minds of young people, that might otherwise remain undeveloped. In order to inform our youthful readers of the prices paid for pet animals we have arranged a price list by which the retail cost of any animal may be seen at once. These prices, it must be understood, are the selling ones for the city of New York and neighborhood, but we do not think they will vary much from prices given in other large cities.

Of course, our readers are aware that there exists a large difference between the retail and wholesale prices—sometimes amounting to one-half or more; this difference is but just, as the dealers sometimes have to keep and care for the animals a long time before getting any returns, and frequently deaths take place, losses against which the dealer must insure himself by making the difference between the wholesale and retail price sufficiently large.

This price list or amateur "Market Report" will be continued from month to month and will be enlarged and corrected from time to time in accordance with the changes in actual prices. We will also try to give early mention of any novelties that may be worth noting.

IMPORTED CAGE BIRDS.

Canaries, *Belgian*, per pair	$3.00 to 15.00
" *French*, each	8.00 to 15.00
" *German, Hartz Mts.*, each	2.50
Gold Finches, each	$1.50
Gold Finch (mules), each	2.50 to 5.00
Bull Finches, each	1.50 to 2.00
Bull Finches (tuned), each	5.00 to 30.00
African Finches, per pair	2.50 to 5.00
Chaf Finches, each	1.50
Linnets, each	1.50 to 2.00
Linnets (mules), each	1.50 to 2.00
Green Linnets, each	1.50
Java Sparrows (blue), each	1.50
Java Sparrows (white), each	3.00 to 4.00
English Sparrows, per pair	1.00
Siskins, each	1.00
Gray Cardinal, each	5.00
Nightingales, each	8.00 to 25.00
Thrushes, each	5.00
Skylarks, each	5.00
Troopials, each	5.00 to 15.00
European blackbirds, each	5.00
Black-caps, each	4.00
Starlings, each	2.50 to 50.00
Ring Doves, each	

AMERICAN CAGE BIRDS.

Canaries, each	
Mocking Birds, each	$1.00 to 10.00
Robins	2.50 to 50.00
Blue Birds ("Blue Robins") each	$1.50 to 2.00
Indigo Birds, each	1.00
Nonpariel, each	1.50 to 2.00
Virginia Cardinal, each	2.50
Bobolinks, each	1.00
Yellow Birds, each	1.00

QUADRUPEDS.

Terriers, *black and tan*, each	$5.00 to 30.00
Terriers, *Scotch and Skye*, each	5.00 to 30.00
Newfoundland Pups, each	10.00 to 15.00
Pomeranian or Spitz "	5.00 to 15.00
Greyhounds, *English*, "	10.00 to 25.00
Greyhounds, *Italian* "	10.00 to 30.00
Guinea-Pigs, *common*, per pair	1.50
Guinea-Pigs, *all white*, "	2.00
Guinea-Pigs, *African*, "	3.00
Squirrels, *gray and black* "	3.00 to 10.00
Squirrels, *all white* "	15.00 to 25.00
Squirrels, *flying* "	3.00 to 4.00
Squirrels, *small red* "	2.00
Rabbits, *common* per pair	1.00 to 2.50
Rabbits, *fancy breed*, according to age and purity of breed, per pair	3.00 to 15.00
Ferrets, *English*, "	15.00
Raccoons, each	4.00 to 5.00
Cats, *Maltese* (males), each	5.00
Cats, *Albinos, pink or blue eyes*, each	3.00 to 5.00
Rats, *white China, pink eyes*, per pair	1.50
Rats, *piebald*, per pair	1.50
Mice, *white, pink eyes*, per pair	0.50
Mice, *piebald*, per pair	0.50

Nature has her language and she is not unveracious, but we don't know all the intricacies of her syntax just yet, and in a hasty reading we may happen to extract the very opposite of her real meaning.

Wood-carving is an industry which is carried to considerable perfection among the Germans, and is fostered by the establishment of carving schools, particularly in districts where the wood used for the work—Spanish walnut, the best walnut the Germans have—is plentiful. There are now 80 such schools in Germany.

Speed of Cannon Balls.—The highest velocity that has been imparted to shot is 1,626 feet per second. This is equal to a mile in 3.2 seconds. The velocity of the earth at the equator, due to rotation on its axis, is 1,000 miles per hour, or a mile in 3.6 seconds. Therefore if a cannon ball were fired due west, and could maintain its initial velocity, it would beat the sun in its apparent journey round the earth.

How Small Birds Migrate in Europe.—According to a writer in *Nature*, the small migratory birds that are unable to perform the flight of 350 miles across the Mediterranean Sea are carried across on the backs of cranes. In the autumn many flocks of cranes may be seen coming from the north, with the first cold blast from that quarter, lying low and uttering a peculiar cry, as if of alarm, as they circle over the cultivated plains. Little birds of every species may be seen flying up to them, while the twittering songs of those already comfortably settled upon their backs may be distinctly heard. But for this kind provision of nature, numerous varieties of small birds would become extinct in northern countries, as the cold winters would kill them.

EXCHANGES.

Only those who are *yearly* subscribers, and whose names are entered on our books have the privilege of inserting exchanges.

Exchanges must be on separate slips of paper or postal cards. If mixed with business matter in letters or cards they are filed away and never reach the printer.

Exchanges must not exceed thirty words.

Buying and selling belong to the advertising department.

We reserve the right to omit the exchange column, when we have not room for it, and the amount of space at our disposal will regulate the number of insertions given to each *exchange*, the preference being always given to those who have not previously used our columns.

Wanted engraver's tools with book of instructions, for a Victor Press, with cabinet, 2 type cases, type, ink roller and furniture complete; perfectly new. L. Warren, 72 Cumberland St., Brooklyn, N. Y.

A Fletcher Foot-Blower, cost $5, as good as new; will exchange for a Cushman, 2 in. or up scroll chuck, or other make; will give a satisfactory trade on the difference in price, if any. Louis Lutz, St. Clair Street, Toledo, O.

I have a lot of "Galaxy" (magazines) which I would like to exchange for an air rifle in good condition, a collection of birds' eggs, or offers. W. B. Greenleaf, 480 La Salle Ave., Chicago, Ill.

I have a Mechanical Telegraph with book of instructions, books, etc., which I wish to exchange for good microscopical objects, mounted on 3 x 1 slips. Address, with list, J. H. Frey, Millersburg, Ohio.

To exchange, "How to Use Microscope," Wells' "Natural Philosophy," and many other books, chemical apparatus, etc , for good photographic camera, and lenses. W. H. Weed, 254 Putnam Ave., Brooklyn, N. Y.

Wanted "Quimby's New Bee Keeping," for "Our Own Birds of the United States," by W. S. Baily; new. Joseph Anthony, Jr., Colota, Whiteside Co., Ill.

Wanted a good book in anatomy, in exchange for a book on chemistry, or for story books. A. G. G., Box 26, Summit, New Jersey.

A German-silver trimmed, patent lined, cocoa flute, cost $4, in good order, for good spy-glass, photo-material, or offers. Ewing McLean, Greencastle, Ind.

I have some fossil shells from the west bank of the Mississippi, to exchange for Indian relics. A. W. S., 187 E. 71st St., N. Y.

I have a magic lantern, Ruby pattern, nearly new, and 5 views; also "Our First Century," bound in leather, cost $7; state what is wanted in exchange. I. N. Spencer, Box. 217, So. Manchester, Conn.

First-class telegraph instrument and attachments, and "Wood's Botany," for bound volumes of periodicals, books, or offers. H. P. Albert, Anderson, Iowa.

Wanted a book on treatment and care of canary, also breeding of same; will give in exchange book named "Market Garden, Flower Garden and Bees," or 40 "Scientific Americans" or "Seaside Libraries;" want also old books. M. J. Mulvihill, Norwalk, Conn.

Coins, minerals, stamps, books, type, fishing tackle (very complete) and fish pole, bronze inkstand, etc., for coins, medals, stamps, war envelopes, old newspapers, and Continental, Colonial and Confederate currency. F. F. Fletcher, 103 Main St., St. Johnsburg, Vt.

Blow-pipe set (cost $10), large illustrated family Bible (cost $7.50), for Wood's Botany, Dana's Geology, or printing press and type. H. W. Noble, Box 134, South Dansville, N. Y.

Wanted, offers for fossil shells from the west coast of Africa. A. W. Seward, 187 E. 71st St.

I have a number of birds' eggs I should like to trade for other birds' eggs; send for list of trading eggs. A. G. G., Box 26, Summit, New Jersey.

For a microscope stand or offers, a 36-inch turning lathe (new) and a number of scientific books; send for list. A. Kendall, Somerville, Mass.

Wanted services of amateur printer with small office (or large), in exchange for an interest in a well-established weekly paper, good size. Eagle Office, Plymouth, N. H.

American Agriculturist microscope, new, cost $15, for amateur photographic apparatus, lever watch, 22 calibre breech-loading sporting rifle or magic lantern of equal value. Wm. A. Walker, Rockland, R. I.

I. T. Bell, Franklin, Pa., has back numbers of Scientific American, Forest and Stream, and Young Scientist, good flute, chessmen, books, etc., for good magic lantern, revolver, scarce coins, or offers.

A steel spring bracket-saw, 2 doz. saw blades, and about 1 doz. patterns for a good stylographic pen or offers; send postal before exchanging. Geo. Oakley, Rutherford, N. J.

A rosewood banjo, 11 inch head, 12 nuts, fully strung, together with lot of dime banjo music and instructions, for microscope, Webster's Unabridged, monkey, squirrel and cage, or offers. J. DeWitt Clark, P. O. Box 37, Brooklyn, N. Y.

For self-inking printing press and type, one Henry rifle, 16 shot, 44 cal., cost $40, in good order, or one double barrel shot gun, barrels London fine twist, or offers. J. B. Garrison, Belton, Bell Co., Texas.

What offers for "The Chefs D'Oeuvre D'Art, Paris Exhibition 1878," cost $16, good as new, bound; 1 large photo camera, complete, cost $95; Scientific American from 1859 to 1880, 4 vols. bound. D. Keesler, Stony Point, N. Y.

Sea shells of Atlantic coast, scientifically marked, for books, old or new magazines, Indian relics, natural history specimens, apparatus; anything. Wilfred Leon Miller, P. O. Box 392, Cape May, N. J.

A new 40 diameter microscope, corals, and minerals, for a stylographic pen, air gun, or offers. J. McBride, 54 Garley St., Chicago.

A dulcimer that cost $20, books and fossils, for a telescope, microscope, fossils, Indian relics, or offers. E. J. Votaw, Salem, Iowa.

A self-inking model press, 5 x 7½, cost $23; $90 worth of scroll-saw designs in lots to suit; Scientific American, 1880; Palliser's Useful Details, $3; for photo outfit or offers. C. H. Parker, Coldbrook Springs, Mass.

Telegraph key and sounder, Frank Leslie's Illustrated Magazines, mounted microscopic objects, natural curiosities, for bull's-eye condenser, photograph camera, Unabridged Webster Dictionary, or offers. W. T. Alan, Greenville, Mercer Co., Pa.

Large magic lantern, spectroscope, pantagraph, for enlarging drawings, rosewood writing desk, man's saddle, for microscope, photo outfit or offers. Thomas Walters, Bergen St., East of Brooklyn Ave., Brooklyn, N. Y.

Model card press, chase 3¼ x 5¼, with 4 fonts type, cases, etc., for good foot lathe. Mills Day, 2 Farmington Av., Hartford, Ct.

French microscope, inclines to any angle, delicate fine motion, neat upright case, cost $17.50, for scientific books; send list to W. Fitz, P.O. Box 2852, New York.

Wanted, Quinby's New Bee Keeping, for Our Own Birds of the United States, by W. S. Baily; new. Joseph Anthony, Jr., Coleta, Whiteside Co., Illinois.

Printing type, small pica; large and small capitals, and small letters; 60 to 65 lbs., including two large cases; also gothic nonpariel, for trade. J. Siler, 1242 Broadway, St. Louis, Mo.

One years' copy of Aldine, cost $5.50, and German accordion, with instructions how to use it, cost $5.00, for offers. Chas. Dempwolf, 86 Benson St., Paterson, N. J.

A Novelty printing press, with type, prints a form 5 x 7 inches, cost $40.00, for a microscope, photographic apparatus, or offers. T. W. Patterson, Warsaw, N. Y.

$80 worth of (nearly new) printing material, minerals, fossils, Aboriginal relics, etc., for scientific books, good American watch, and offers. F. M. Farrell, Cobden, Union Co., Ills.

Rocks, minerals, fossils and fresh water shells for microscope stand, $20 to $75, also for objectives, turning lathe type, and tools. D. D. Babcock, South Dansville, N. Y.

Magic lantern, in good order, condensing lens, 2½ in. diameter, 8 slides. For small photographic camera or offers. H. A. Giddings, 4 Union Place, Classon Ave., Brooklyn.

HOME ARTS

VOL. VI. NEW YORK, FEBRUARY, 1883. No. 2.

Why and How We are Enabled to Cut One Metal with Another.

BY JOSHUA ROSE.

SOME philosopher has said that the degree of civilization of a people could be measured by their consumption of iron. It is true that as nations progress they increase the employment of iron in the constructive arts. But the age of iron, as the era of iron consumption has been termed, promises to be succeeded by an age of steel, because it is steel that has enabled us to cut and shape iron so quickly as to enable it to be made and formed so cheaply that it could compete in price with wood and stone in the construction of buildings, and with wood in the construction of vehicles and other articles where lightness as well as strength is a necessity. The steel of which I desire more particularly to speak is known by the general name of cast-steel, and more definitely by the name of tool-steel, since it is the special grade or kind of steel from which cutting tools are made. But even this kind of steel is made in many different grades or kinds, according to the purpose for which it is to be used. It is sufficient for our purpose, however, to state that the cutting quality of steel is due to its being harder than other metals, and to the fact that by a simple process it can be what is termed *hardened*, which means given an increased degree of hardness.

This process consists in heating it and then suddenly cooling it, and the degree of hardness depends upon the degree to which it is heated and the suddenness with which it is cooled after being heated.

The harder the metal it is to cut the more the steel must be hardened. For example, if we take a piece of steel and cut it into two pieces, and then heat one piece red-hot and quench it in water, it will cut the soft piece. Suppose, now, that we take the hardened piece and again heat it to a red heat and then per-

mit it to cool slowly, and it will have become soft again.

The highest degree to which a piece of steel may be hardened is attained by heating it to a red heat and cooling it in mercury, but it is not found necessary to use mercury for the cooling process in the case of any ordinary metal-cutting processes, because salt water and generally pure water is found to extract the heat sufficiently quick to make the steel hard enough. Between this degree of greatest hardness, however, and the degree of greatest softness of any piece of steel, there are a number of degrees of hardness that are known by the term, *temper*, and a piece of steel is tempered when it is given any degree of hardness above that it possesses as it is in the forged bar and less than its greatest degree of hardness.

All cutting tools that are not left fully hardened are tempered to a degree that has been found most desirable for the purpose for which the tool is to be used.

The necessity for tempering a tool arises from the fact that hardening a piece of steel decreases its strength and makes it brittle, while for many cutting purposes strength in the tool is a necessity, as is the case with a knife blade. The cutting edge of a knife would last much longer if the blade was fully hardened, but that would weaken it so much that it would break very easily; hence it is first hardened and then tempered, the tempering process consisting of heating it to some degree less than that to which it was heated to harden it, and serving to restore the strength that was lost in the hardening. The object is thus to give to every tool as much hardness or as great a degree of temper as possible, while having it strong enough for its cutting duty. In order that the degree of temper may be uniform for a given purpose it is necessary that (supposing them to be all made from the same quality and grade of steel) they all be heated to the same temperature for the hardening process, and then reheated to the same degree for the tempering process. It may be remarked, however, that a variation in the heat for the tempering process is a greater detriment than one in the heat for the hardening, because the effect upon the steel is greater.

Fortunately, however, Nature has given us an excellent gauge whereby we can know to a certainty how much a piece of steel is heated so long as its temperature is not greater than 600 degrees or less than 000 degrees, and it is between these two temperatures that the degrees of temper for all cutting tools is obtained.

If a piece of steel, either hardened or quite soft, have its surface brightened and is slowly heated, it will, when it is heated to 600 degrees, assume a yellow color. As it becomes more heated the yellow deepens, until it passes to a red; from that it passes (as the steel gets still more heated) through various shades of purple, then to blue, and finally to a very pale blue, with a slight green tinge, which appears when the steel is heated to 000 degrees.

It is clear, then, that if a piece of steel has been hardened, we may know how far its tempering has proceeded; or, in other words, to what extent we have at any point of time reheated it by the color that

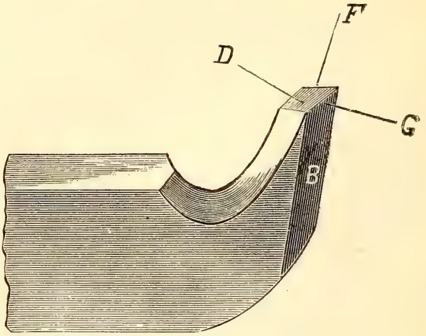

Fig. 1.

has appeared upon its brightened surface. Hence this process is termed color tempering.

Now, since the colors will appear upon soft as well as upon hardened steel, their appearance does not tell us anything more than that it has been heated to a certain degree, and that if the steel had been previously hardened, then it is tempered to a degree corresponding to the color on its surface.

The degrees of temper corresponding to

the various shades of yellow are suitable to metal-cutting tools; those corresponding to the reds and browns are suitable for tools for cutting wood. The purples are for edge tools and drilling purposes, and the blues for metal-cutting chisels or steel to have great elasticity, as in the case of carriage springs.

Two examples of the manner in which steel tools are used to cut iron are given in the accompanying engravings; the first is a tool for that king of all metal-cutting machines, the lathe. The hook end of the tool in Fig. 1 is hardened, and the faces B and D are ground flat on a grindstone, giving to the tool, cutting edges at F and G. In Fig. 2 the tool is shown in action; the work is revolved towards the tool, and the tool is slowly moved in the direction of the length or axis of the work, the result being that it removes a spiral ribbon of metal termed the cutting or chip, whose form is very accurately shown in the engraving.

Fig. 3 shows the method of cutting flat surfaces. The work is held in a vise fastened to one part of the machine, while the tool is held by another part. Then either the tool is pushed over the work or the work is pulled beneath the tool, and in either case the tool takes off a cutting very similar to that shown in Fig. 2.

In other kinds of tools the metal is severed by sheer pressure, as in the case of holes that are punched or plates of iron that are cut by powerful machines, whose action corresponds to a pair of common scissors, only that in the machines one jaw only moves, while in scissors both move. All the difference that the hardness of the metal to be cut makes is that it must be cut slower, and the tools must be harder and stronger.

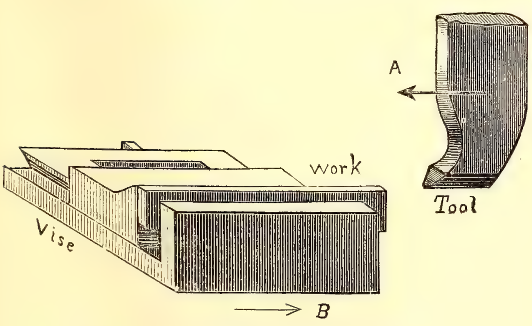

Fig. 3.

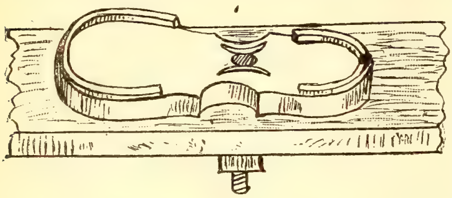
Practical Hints on the Construction of the Violin—IV.

WE promised in our last article, as the readers of the YOUNG SCIENTIST will remember, to describe the manner of working the inside of the violin-plates and of regulating their thickness.

We will suppose that the outsides of the plates have been carefully finished and well modeled. This being done, the workman turns his plate on the work-bench, as shown in the figure, and whittles out the wood with a gouge until the plate is of a uniform thickness—say a quarter of an inch. Let us now imagine that we are finishing the back. The backs of all good violins are found to be twice as thick in

the centre as at the outer edges, and it is in this that the operator's care and judgment are put to the highest test. Not only must the back be graded regularly



from the centre to the edges, and have its inner side as smooth and as perfectly finished as the outside, but it must be also capable of producing a certain number of vibrations in a given time.

In order that the operator may have a fixed scale to guide him in his work, let him take the length of the body of his instrument, lay it out on a piece of wood, and divide it into 72 equal parts. This will form a very convenient scale of measurement.

Let him then take his callipers, and adjust them so that they will take in just two parts of the scale. Let him then work down the centre of the back until it is exactly two parts thick. He may then commence to thin the plate towards the outer edges until the edges show one part in such a manner as that the plate will grow gradually thinner from the centre to the outside, like a wedge.

When this has been carefully done, he may test the plate for sound. In order to discover the proper pitch of the back of a violin a considerable amount of experiment will be necessary on the part of the amateur. When the back of a violin has been properly worked out it should give, on percussion, the note *Do* of 512 single vibrations in a second. It requires a good ear to perceive this, for the reason that a sound emitted by a piece of wood is not so clear or so well defined as that given out by a musical instrument. The best way to arrive at a good result is to procure a sliding *pitch-pipe* and set it at *Do* 512 vibrations, or *C* on the *G* string of a good violin properly tuned. Let the amateur then understand that there are *three nodal lines* in the back of the violin (or lines of no vibration). One of these lines runs down the centre of the back, and the two others cross this centre line at right angles, one through the middle of the larger end, and the other through the middle of the smaller end (when I say the middle I mean about the middle). Let the amateur take hold of the back where two of these nodal lines intersect with his forefinger and thumb, and strike the plate with his knuckle or with a piece of wood, and he will find that it will emit a very well defined sound, which he will find, on blowing into his pitch-pipe, to be sharper or flatter than the note given by the pitch-pipe. If the note emitted by his newly-made back be flatter than 512 vibrations in a second, he may throw the back away as worthless—the wood is of bad quality, and it will never make a good violin. If, on the contrary, the back gives a sharper note than his pitch-pipe, he is all right. All he has to do in that case is to carefully thin the back with fine sand-paper until it gives the required note. When all this has been carefully done, he may attach the back to the ribs. In doing this let him take thin hot glue, and with a brush run it around the edge of the plate and also around the ribs where they are to be joined to the plate—this must be done quickly, that the glue may not have time to set. He then lays the ribs which are still attached to the mold on the back, and, with small clamps, brings them tightly together. The clamps should not be removed before eight or ten hours.

The next operation is the finishing of the belly or upper plate of the violin. This will be found much more pleasant than the working of the back—first, because the wood is softer, and secondly, because it may be made of equal thickness throughout. Indeed, the bellies of the best violins are of this style—equal thickness throughout. But it must be borne in mind that the belly must be thinner than the thickest part of the back. The timber of the belly is more resonant than that of the back, and, for the same dimensions, gives a sharper tone. Consequently, if the both tables were of the same degree of thickness, the tone of the belly would be altogether too high for

the back, and the instrument would be worthless. It will not do to have both plates in unison, or giving the same sound. The belly must be a whole tone, or at least more than a semitone sharper than the back, to give good results. If the back gives *C* 512 vibrations, the belly should give *D*, the next whole tone above. The amateur should, therefore, carefully work out the belly of his instrument until he has arrived at the proper degree of thickness, and he must bear in mind that the better he does his work the more perfect will be his instrument.

All tools should be kept perfectly sharp, so that the wood may not be torn off but cleanly and smoothly cut. The inside of a violin should be as carefully finished as the outside.

There is something we forgot to speak of in its proper place, namely, the cutting of the grooves around the edges of the plates and the inserting of the *fillets* or *purfling*. We will return to this part of the work in our next article, and explain the manner of inserting the bass bar—a thing which is one of the great secrets of violin-making.

Amateur Wood-Carving.

SOME excellent lessons on wood-carving have appeared in previous numbers of the YOUNG SCIENTIST, to which we gladly refer those of our readers who have not attempted the art heretofore, but who intend to practice it now, with a view of becoming adepts. Wood-carving has always been to the uninitiated a *terra incognito*, but, like most of the arts practiced for industrial and decorative purposes, the unknown and mysterious gradually disappear on closer acquaintance, until the art becomes as familiar as any other of our occupations.

No amateur will be able to work with satisfaction, or turn out creditable results, unless he possesses the necessary tools and appliances for doing so. In the articles referred to some of the tools required by the carver were illustrated and described. In addition to the tools already spoken of, we may add the following, which will be found more or less useful for various purposes: A small hard brush, for brushing out dust and small chips from diaper or other depressed work. A marking-gauge of the ordinary type, a wood rasp, and a riffler, same as shown at Fig. 1, which is an excellent tool for

Fig. 1.

finishing up nooks and corners. A pair of medium-sized, egg-shaped callipers will often be found useful. We show a pair, which we think is the most suitable in shape for the carver, at Fig. 2. A pair of

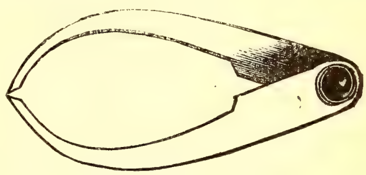


Fig. 2.

spring dividers will also be found useful; and these should be good and about the style shown at Fig. 3. Although most of the paring and cutting may be accom-

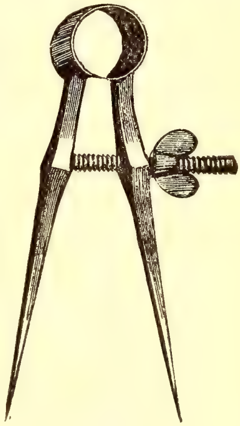

Fig. 3.

plished by pressure alone, or by a gentle tap on the handle of the cutting tool with the palm of the hand, there will be some cases where it will be necessary to make

use of a mallet; the one shown at Fig. 4 presents, perhaps, the handiest shape, as it is always in the right position when in the hand. It may be made of beech, hickory or iron-wood. It should be light and handy. Another useful contrivance that can be easily made by any handy amateur is a "router," sometimes called by workmen a "hag's tooth." It consists of a piece of hard wood, preferably beech, about two inches wide and one and a half or more inches thick, and from five to eight inches long, with a slot or mortice cut through the centre to admit a chisel or other cutting tool, which is held in the slot the same as a plane iron is kept in place. Fig. 5 shows the block, A, and the cutter, B.

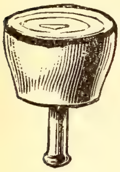

Fig. 4.

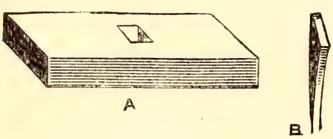

Fig. 5.

The tool is especially useful for regulating the depth of groundwork of panels, etc. It can be made of various sizes, but the most useful will be of the size named, and made to admit a cutter about a quarter of an inch wide. In using this tool the groundwork is first cut out, to some extent, by a quick bent tool; the cutter is set to the depth required, and by working the tool backwards and forwards, a perfectly flat surface is obtained. The stones required for sharpening carving tools should be the very best that can be obtained. Arkansas or Turkey stones are probably the best, but we have got good results from Washita stones; perhaps for slips and other small stones it is better to procure Arkansas ones, as they generally give the best satisfaction for sharpening inside work, such as the inside of gouges, veining tools, etc. In general, a quick cutting stone is the best for large tools, and a fine-grained, slow cutting one for the small and finer tools. With small veiners and parting tools a piece of pine is cut—across the grain—so as to fit inside of the tool to be sharpened, and emery powder and oil is then used to rub out the inside of the tool. Other tools and contrivances, such as small files of various sizes, scrapers of different shapes, and cutters of suitable forms, will occur as wants to the amateur, when he enlarges his field of labor.

After the inside of a tool has been thoroughly rubbed out, and there is not much danger of sharpening it too much from the inside, the outside edge should be finished off by sharpening on the main oil-stone, and when this is done, the tool should be laid flat on the stone and moved gently to and fro, until the required edge is obtained. Care should be taken to keep the edge of the tools perfectly square and even.

In sharpening the outside of tools with a slip the tool should be held in the left hand; then move the stone sharply up and down the edge with the right hand, except in cases of flat tools, when the stone may be placed on the bench, and both hands used to grasp the tool. The best of sperm-oil should be used as a lubricant on the stone. Other clean oils will answer tolerably well, but it is always better to use sperm or olive. Sometimes emery powder or flour emery is used on the stone, to increase the cutting power, but this is not a desirable practice. To put a finishing, clean-cutting edge on the tools, a piece of leather may be used. This may be glued on the top of the oil-stone box, or it may be fastened on an independent piece of wood. The leather should be plentifully saturated with hard mutton tallow and cro-

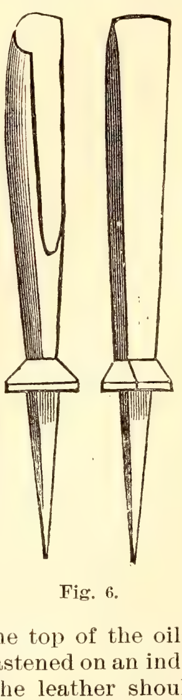

Fig. 6.

cus powder well rubbed in before a fire. When properly made, this strop will be found to give a keen edge to the tools, and by a little ingenuity in the make-up, may be made so as to answer in sharpening the inside, as well as the outside, of tools.

Fig. 6 shows two tools properly sharpened. It will be noticed that the basils or bevels of the tools are long and evenly made.

A good way of testing the keenness of edge on a tool is to try it on a piece of soft pine, cutting across the grain, when, if the tool is properly sharpened, a clean cut, without any tearing of the grain, will be the result.

In future issues of the YOUNG SCIENTIST examples for carving, with full instructions as to operation and materials, will be given.

Scroll-Saw Novelty.

NO doubt many of our readers who own scroll-saws will be glad to get a design for making a handsome, and at the same time efficient, summer fire-screen, like the one we illustrate and describe below. Fig. 1 shows the screen completed on a reduced

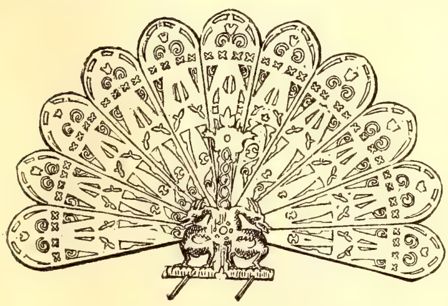

Fig. 1.

scale. The actual height of screen from floor will be about twenty and a half inches to top of central leaf. Eleven of the leaves (Fig. 2), two uprights (Fig. 3), and two cross-pieces (Fig. 4), complete the design. To work the leaves a fine close-grain but light wood should be chosen, not more than $\frac{1}{8}$ inch in thickness; to avoid monotony and trouble, at least four leaves may be worked at a time

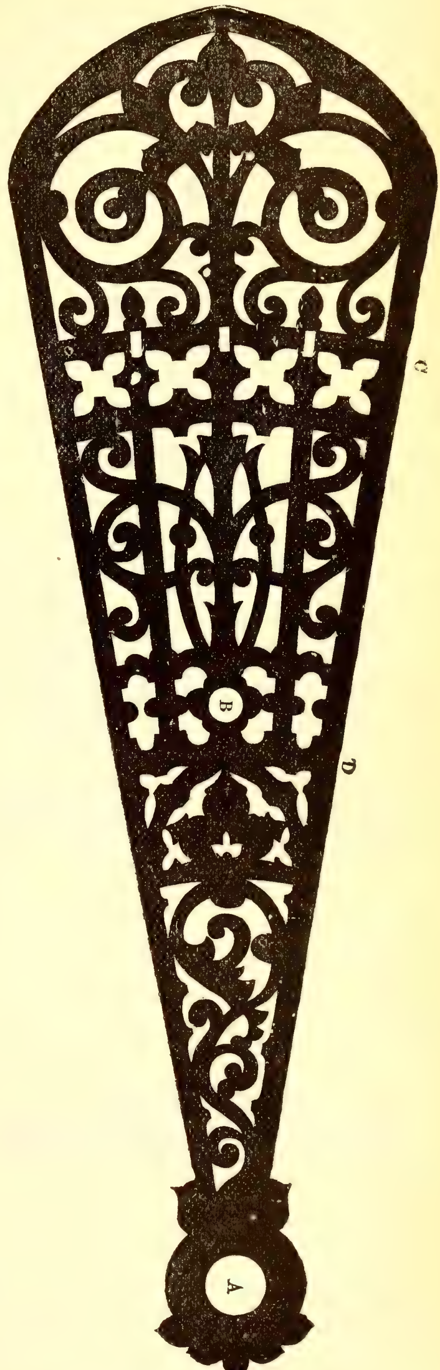

Fig. 2.

by bradding the wood together, seeing that the brads pierce only those parts of the design that are cut away, and working those portions the last. For the uprights (Fig. 3) a thicker piece of wood should be chosen, ¼ to ⅜ of an inch. One of these for the back would be best left

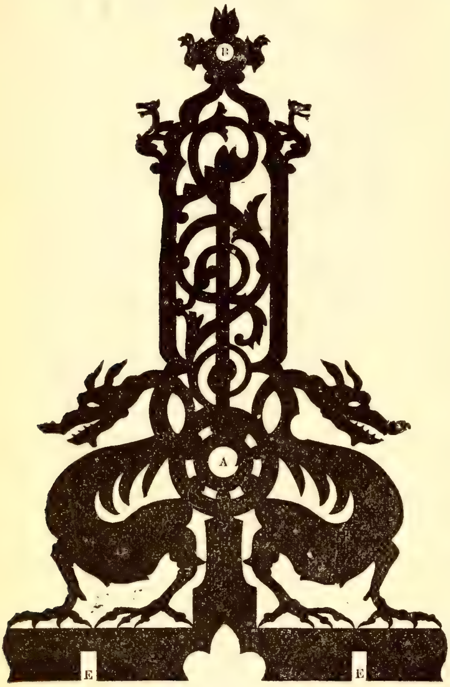

Fig. 3.

solid, the outline only cut; this gives more weight to the base. Two pieces (Fig. 4) should be worked in the thickness of the uprights. These pieces and the standards are notched into each other, as shown at E, E, in Figs. 3 and 4. Between

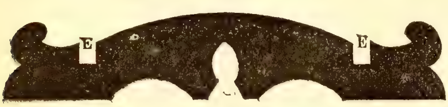

Fig. 4.

these, when put together, fit a square block of wood weighted, or else stand the whole on a wood block for the base, to which it should be fixed. To put the leaves together, thread them with ribbon like an ordinary lady's fan. This is so simple, and within everyone's reach, that it is not necessary to explain the construction; the ribbon is fixed in its place with glue. A peg fitting tightly connecting the uprights (at A, A, as in the design) is first passed through one upright, then through the holes A of the leaves, and fits into the back upright. If preferred it may be longer than the whole thickness it connects, and fixed with a peg through a hole at either end. A peg or brass nail hung at the back by a cord can be used to keep the fan shut up. By closing the leaves and passing the peg through the holes B, B, the fan will be kept closed when not required for use.

For alternative treatment the fan leaves might be cut in solid wood, and painted with any suitable design. In this case the uprights should be more simply made, probably the necessary uprights, in a simple form, based on this—⊥, would be best. The monotony of the work may be

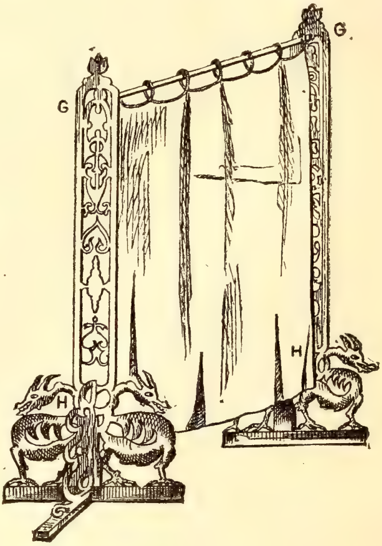

Fig. 5.

relieved by the leaves left solid between C and D (save the holes B), affording space for a spray of flowers to be painted.

If the uprights (Fig. 3) of the fan-screen are made much higher, and the lower part of the design is cut and placed at right angles, as shown in Fig. 5, the frame

connected by bars at G G, and H H, will be a substitute for a metal framework made for a similar purpose. A curtain in needlework hangs well on such a frame as this, and fulfils the purpose of screening what it is wished to hide as well, or better than many of the more elaborate designs.

The total length of leaf from point to point is 17½ inches; greatest width at top, 5½ inches; height of standard, 12¼ inches; width at bottom, 8 inches; width of shaft, 2½ inches. Cross feet, Fig. 4, are 7 inches long and one and a half inches wide. Walnut or mahogany would make excellent material for this screen.

Something About Saws.

BY "OUR NED."

IT is an old saying that "A bad workman quarrels with his tools." It might also be said with equal force that "Bad tools make a good workman cranky." Particularly is this so if the "bad" tool happens to be a saw.

An amateur's first experience with a new saw—cross-cut or rip—is generally of a pleasant nature, because then the saws are straight, sharp, and in good condition, and a saw in fine condition and sharp is one of the most pleasing tools to work with, and the most unsatisfactory if the reverse is the case. The reader will notice that I have made a distinction with a difference in using the terms "condition" and "sharp," and I will clear up this point before proceeding further. I use the term "good condition" to denote that the blade is in perfect order, devoid of "kinks" or "buckles," the line of teeth regular, and this line slightly curved, the teeth of equal size and "set," and at the proper angle with regard to the line of teeth. When all these things are complied with, in accordance with well-defined rules for the purpose, the saw will cut tolerably well, though it may not be very sharp. To be sharp a saw must possess keen points, and the edges of each tooth must be sharp and well-defined, and the angles of each tooth, with regard to the sides of the saw, must be regular and in accordance with rules I shall explain further on. A saw may be "sharp," yet perfectly useless as a cutting tool; therefore, let me impress on your minds the necessity of keeping this tool in the best of order. It is impossible to cut off a piece of board, plank or scantling straight and square with a saw whose teeth are formed something after the fashion of those shown in Fig. A.

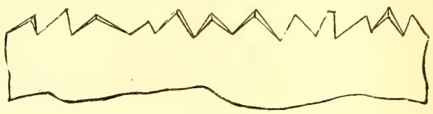

Fig. A.

This engraving, in a measure, represents the condition of many amateur cross-cut saws I have met with, and which, to my knowledge, have caused many an ingenious amateur to abandon amateur work altogether, so discouraging have been the results of their struggling labors with the tool. It might well be said of persons using such an instrument that they are on "a ragged edge."

Now, then, how can the amateur take care of his saws and keep them in good condition? I will endeavor to answer this question in a plain way, so that the reader will not get mystified or "mixed." In the first place, if you have not already purchased saws, see to it that, when you do buy, you get good ones, saws made by some good reliable firm who have earned a reputation for the excellence and efficiency of their manufactures. Remember that in this, as in all similar matters, you must pay a good price for a good article. Cheap saws, like cheap fruit, may look very well, but they contain the canker-worm of disappointment in their cores. When the saws are once taken home they should be rubbed over with an oily rag and either hung up or placed carefully away in a chest, if not in use. Never try to force a saw through a piece of stuff; if the material being sawed should warp or twist, as is often the case while being cut, and close up the saw-kerf so as to pinch the saw, any further attempt at sawing should cease, until the kerf is wedged open or the saw otherwise released. It is

during the forcing process that most of the "buckles" in saws take place. Sometimes saws may be "buckled" or "kinked" when not in use by having heavy weights piled on them, or by receiving a sudden blow, or by falling some considerable distance; all these adverse chances should be strictly guarded against. Another thing: before cutting any stuff, clean it well off, making sure that all sand, grit, and dust are removed. Avoid knots wherever you can, and be sure and examine the stuff where the saw has to travel, more particularly if the stuff to be worked is old or has been used before, as nails, tack or brad points may have been left in, and if the saw teeth should come in contact with them it would prove almost fatal to the tool. Never permit the tool to rust. If it should get wet, or accidentally get acid of any kind spilled on it, wipe it off clean and dry, and rub it over with an oily rag. Saws always cut better for being bright and clean. Care for a saw as you would for your razor and the results will be equally satisfactory.

The next thing to be considered is how to file the saw when it gets out of order. Of course, a saw right from the store, if in good condition when bought, ought to stand the slight wear and tear of amateur work for a year or more, if the foregoing

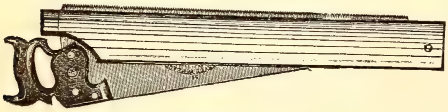

Fig. B.

directions are followed, but there will come a time when the tool must be filed. Let us suppose that time is at hand. The first thing necessary will be clamps or holders, between which the saw must be firmly held. Fig. B shows a side view of these clamps, with the saw in position, ready to be filed. It will be seen that the edge of the saw, or the "cutting edge," as it is called, stands above the bevelled edges of the clamps some little distance; this is to allow of the file being used with the handle hanging downward towards the operator, as shown at Fig. C.

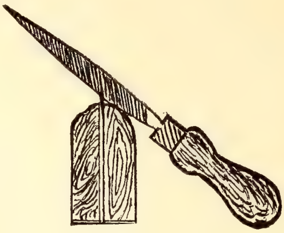

Fig. C.

These clamps may be made of pine, but had better be of hard wood. The end next the point of the saw may have a heavy wood screw in it, as shown in the drawing. The pieces forming the clamp should not be less than three inches wide and from seven-eighths to one and a quarter inches thick, and have the upper edges chamfered or rounded off, as shown in the section at Fig. C.

The clamps and saw should be placed in the jaws of the bench screw and firmly held in place. If the saw is a cross-cut, and has sufficient "set," and none of the teeth have been broken short by running against nails or other hard substances, the work will be very easy, as all you will have to do will be to set the file at such an angle as will fit it to the teeth as they now are. This done, draw the file to and fro very carefully, minding that the file does not press too heavily on any particular part of the tooth, and, above all, be mindful that the point of the tooth is not shortened, as this is one of the main things to be guarded against. Remember that in filing a cross-cut saw, the point of the file should always be towards the point of the saw, and this compels you to file every other tooth first, and when done on one side, the clamps and saw must be taken out of the grip of the bench screw and turned with the unfiled side toward the filer, who must treat this side of the saw just as he treated the first side. Now look along the edge of the saw, and, if your work has been done with anything like regularity, there will be a continuous angular groove along the edge of the saw, into which a needle may be laid

and slid from one end to the other of the saw. Now this is the simplest of ways to file a saw, but it is very seldom successful, from the fact that it is almost impossible to follow the lines of angles first made in the saw without making some teeth smaller than others, and again, it is *unscientific*, and therefore unsound. Consequently, it is much better to learn how to file a saw on correct principles.

Three kinds of teeth are used on hand-saws for cross-cutting; one for cutting very soft wood, such as pine, whitewood, basswood, butternut and chestnut. This kind of a tooth, enlarged, is shown at Fig. D.

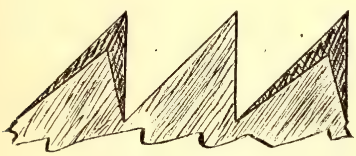

Fig. D.

I do not advise the use of this tooth for the amateur, for many reasons, among which may be mentioned the difficulty of keeping it in order, its liability to break and otherwise get dull, and its unfitness for use on hard woods.

Fig. E shows teeth that are adapted for

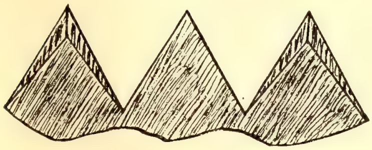

Fig. E.

either hard or soft wood, and are the teeth the amateur should always adopt, as they will work with tolerable ease in either case.

Fig. F shows three teeth adapted particularly for hard woods. It will be noticed that these teeth have wide bases and are more obtuse than the teeth shown in the two previous examples. These three examples of teeth show all that the amateur will care to know of saw teeth suitable for cutting across the fibres of wood, hard or soft. Of course, these shapes may be slightly varied to suit conditions, but the principles involved will always remain the same.

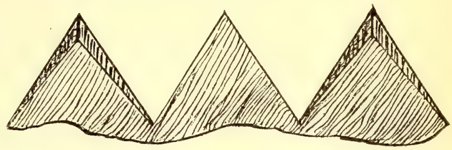

Fig. F.

Portions of saws, showing the teeth about the right size for working, are herewith illustrated, giving the reader an idea of what the saw should be.

Fig. G shows the teeth for soft wood, the same as shown at Fig. D. Fig. H shows the teeth suitable for either hard or soft woods.

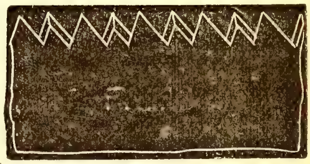

Fig. G.

This is the style of tooth I recommend for amateur use. It will not cut so rapidly as the teeth shown in Fig. G, but it will give better satisfaction all round.

Fig. H.

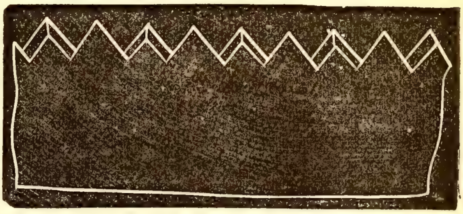

Fig. K.

Fig. K shows the teeth best adapted for cutting hard wood, and it shows the teeth about the size they should be for an ordinary hand-saw.

So far I have only dealt with hand-saws for cross-cutting; in subsequent issues of the Young Scientist I will have something to say on ripping-saws, which require a different mode of treatment than those I have mentioned. The several

other saws, too, which the amateur will have occasion to use, must not be overlooked in future numbers.

Sea Anemones.

BY A. W. ROBERTS.

MARINE anemones belong to the polyps or anthozoa, which consist of cylindrical animals with an opening (the mouth) in the centre of the upper end. This mouth is surrounded by six, eight, or many more hollow tentacles, which are used to seize the food. As soon as the food is passed to the mouth it is pressed down into a central longitudinal bag or inner tube (the stomach), where it is retained until all the nutriment has been extracted; the residue is then passed out through the same opening through which it was received. This having been completed, the nutritious matter passes through the lower open end of the stomach into the cavity of the body, and thence upward into the space between the walls of the stomach and the body.

This space is divided, by radiating partitions, into many longitudinal sections or tubes, which continue into the hollow of one or several tentacles. As will easily be understood, the nutritious matter can reach the extreme part of every tentacle. The polyps either live singly or in colonies, in which latter case they form the coral reefs; polyps or anemones which live singly are larger, but both display a wondrous beauty of form and color.

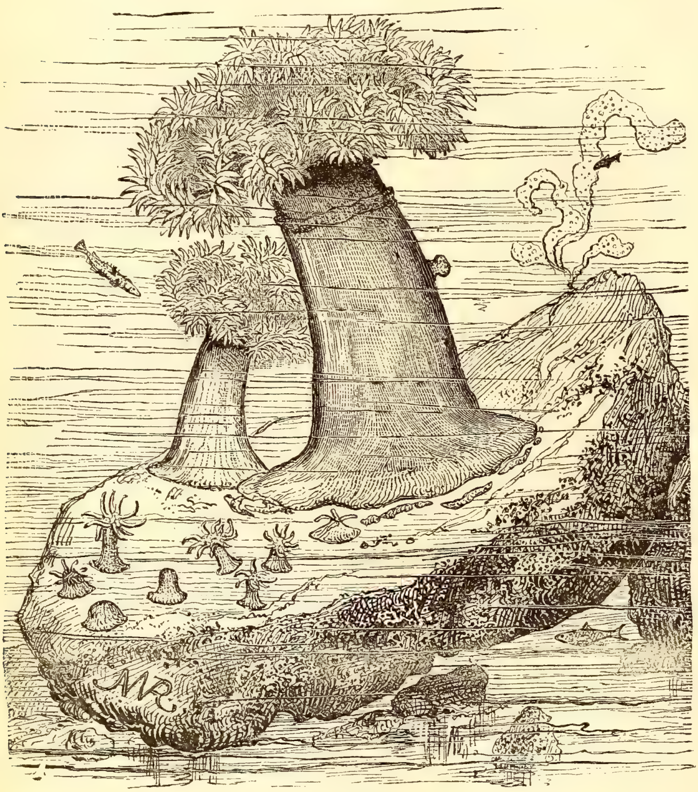

Fig. 1.

The fringed sea anemone *(Metridium marginatum)* is the most common among the anemones of the northern part of North America. It can be easily distinguished by the mass of soft, plumy tentacles that surround its disk. When contracted it looks like a mere lump of brownish or whitish jelly, but, when fully expanded, it displays such wondrous form, grace, and beauty as to hold the attention of the most careless beholder. "From the extended base," says Prof. Verrill, "the body rises in the form of a tall, smooth column, sometimes cylindrical, sometimes tapering slightly to the middle, and then enlarging toward the summit. Toward the top the column is surrounded by a circular, thickened fold, above which the character suddenly changes, the skin becoming thinner and more translucent, so that the internal radi-

ating partitions are visible through it. This part expands upward and outward to the margin, which is folded into numerous deep undulations or frills, which are everywhere covered with numerous fine, short, crowded tentacles." In color this variety of anemones varies from pure white, through all the grades of the browns, often pink, salmon color, and at times beautifully mottled. When the anemone slowly glides along the smooth surface of a rock, or up the glass walls of an aquarium, it often detaches (by contraction) small particles of i's body (from the base or foot part on which it moves). In the course of a few days these begin to develop tentacles, as shown in the illustration, Fig. 1. Other varieties propagate by budding from the side of the column, and by small egg-like bodies which are ejected from the mouth. The white-armed anemone (*Sagartia leucolena*) shown at the right hand in Fig. 2, is a small variety found in great abundance on the submerged timbers of all the public and private swimming baths that are stationed in summer time at the down town section of New York City, particularly Hall's swimming baths at the Battery. The small salmon colored anemone, seen at the left hand in the illustration, is likewise to be met with in immense quantities at Baxter's and other swimming baths situated on the East River from Fifty-first Street and higher up.

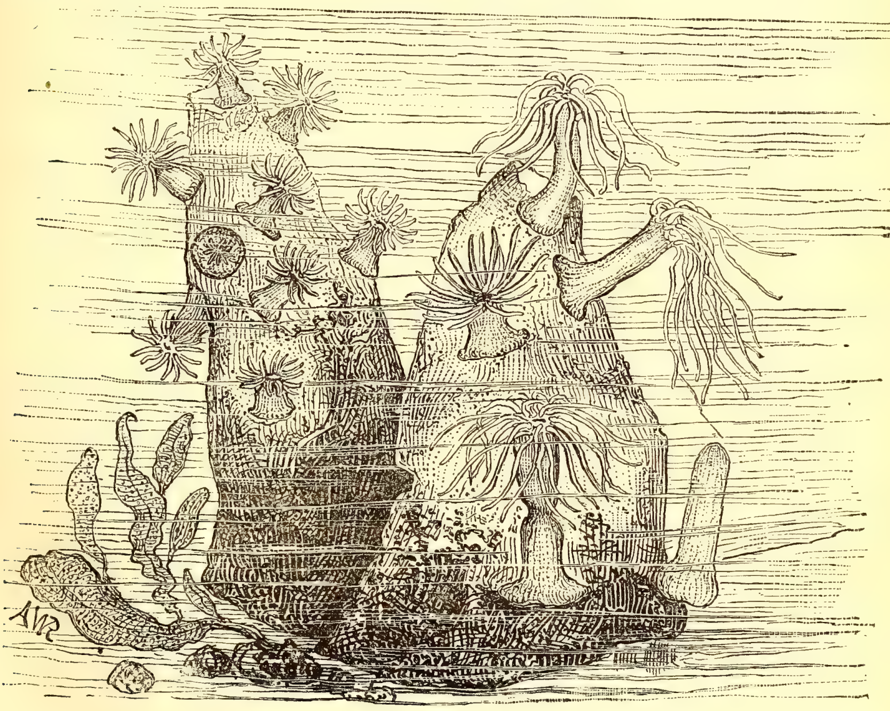

Fig. 2.

The stout-armed anemone (*Tœlia crassicornis*) which for short is called by keepers of aquaria the "Crass," is the largest and most brilliant of all the North American anemones. Its body and disk are brilliantly marked with red and white strips. It is a ravenous feeder and does not hesitate to take into its capacious maw a good sized mussel, or even a fish, if it but once obtains a good hold of it with its tentacles. All the specimens that I have had of this variety of ane-

mone, were obtained by the cod and halibut fishermen, but I was never successful in keeping them alive for more than a month at a time, and I have often thought that this was due to the absence of the great pressure of water, and the greatly subdued light which exists at the bottom of the ocean where they were caught.

In the English aquaria this same anemone has been kept as long as ten years. At one time I had seven varieties of English anemones in my tanks, and curious to relate they all outlived both the American and German varieties, some having lived from the opening of the aquarium till its closing, a period of four years.

I also had several collections of Bermuda anemones, but they too were delicate, with the exception of a medium sized variety of a magnificient light and dark maroon color. This variety was very hardy, and reproduced both by division and eggs, which it ejected from its mouth in large quantities. When collecting anemones at night time at Wood's Hole, on the Massachusetts Coast, the tender skin on the inner part of my fore-arm was constantly blistered. This arose from the fact that the anemones when being taken with a scraper throw off and surround themselves with quantities of a transparent and gelatinous fluid, which when applied to the tongue instantly blisters it. They are undoubtedly provided with this peculiar material by nature as a means of defence. They are also provided with numerous *lasso cells* in which very minute, long, and thread like " lassoes " are curled up, and when capturing a live fish they project them from all directions. With these invisible threads the fish is not only entangled, but is also stung and held fast with the aid of the tentacles. As an illustration of the wonderful reproductive properties of the anemones, and their great tenacity of life, I will, in the next number, relate several interesting experiments that I have made when curator of different public aquaria.

— There lives more faith in honest doubts, believe me, than in half the creeds.—*Tennyson.*

The Late Transit of Venus; Its Nature and Utility.

BY BERLIN H. WRIGHT.

AN event which attracted great attention from all classes, and will be forever remembered by astronomers as the greatest astronomical event of the nineteenth century, was the transit of the planet Venus across the sun's disc on the 6th of last December. The unscientific naturally ask the reason of the great commotion made by the passage of our sister planet between us and the ruler of our system, appearing simply as a small black spot moving slowly across the fiery face of the sun. Admitting that it is a very unusual occurrence; that but four such events have occurred of which the world has record, and that the next one will not occur until June, 2004, aside from these facts, why have so many hundred thousand dollars been expended in fitting out expeditions to distant parts to observe this transit? The answer is that through this phenomenon astronomers hope to solve a celestial problem which has baffled the skill of the most learned heads for 4,000 years—the actual distance from our earth to the sun, and from that as a base of calculation, the distance of all the other planets from the sun, and in fact that distance is used as a " base line " from which all the other elements of the solar system are computed. Before explaining how these results are brought about we will explain more fully the nature of the phenomena.

Venus revolves about the sun once in 225 days, and the earth in 365 days. These are called *siderial* revolutions, or revolutions as seen from the sun. But to an inhabitant of the earth Venus has not made a revolution around the sun, because at the end of 225 days she is not in the same apparent place, with respect to the sun, as at starting. Suppose the planets to be in conjunction at the points *b* and *a* in Fig. 1. When Venus has made a complete revolution the earth has only reached the point *c*. It takes Venus 2½ of her years to overtake the earth, or to come into the same position with regard

to the sun; this is called a synodic revolution. In 584 days after the planets start together from *a* and *b* they will again be in the same relative position with respect to the sun, and if, as represented,

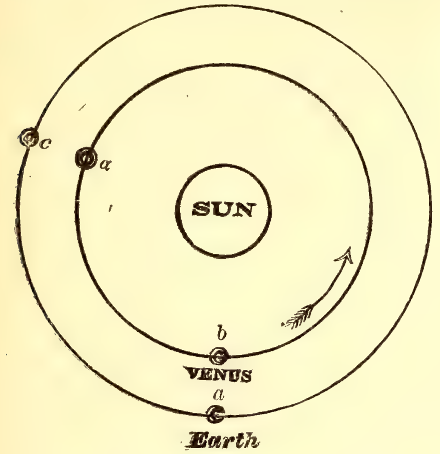

Fig. 1.

the orbits of these planets were in the same plane, a transit would occur every 584 days. But such is not the case; the orbit of Venus intersects the earth's path, as do the orbits of all the planets, and may be compared to barrel hoops shoved

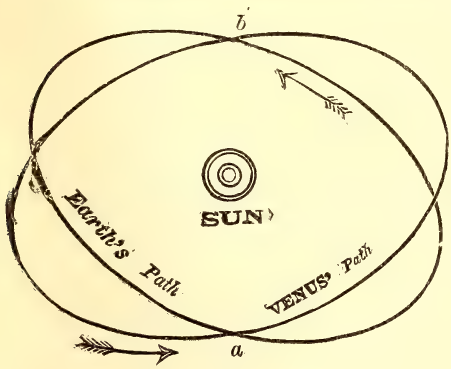

Fig. 2.

through each other, and the points of intersection, *a* and *b* in Fig. 2, are called the Nodes. The Node *a*, where the planet passes above the earth's path, is called the Ascending Node, and 180° from there, at *b*, where it passes beneath the ecliptic, the Descending Node. Now suppose Venus in inferior conjunction or between the earth and sun, as at *b* in Fig. 1, and the earth to be at that point, *a*, in its orbit where the orbit of Venus intersects it; then must Venus make a transit, and only at the points *a* and *b* can a transit occur. It is found that about thirteen of Venus' years equals eight of the earth's, and that about 235 of the earth's equals 382 of Venus'. Hence, having known the date of a former transit, the years when others may occur can readily be obtained. They cannot recur in less than eight years, and if not then 235 years must elapse before another can occur at the *same* Node, or 105 at the *other* Node.

"How do you hope to arrive at the exact distance from the earth to the sun from observations of a transit of Venus?" We will endeavor to give a simple explanation of a very difficult problem.

Two observers, situated at widely different points upon the earth, as at N and S in Fig. 3, will see Venus projected upon the sun's disc at different places; the one at N will see Venus at H, and the other at W, and the two lines, *a c* and *b d*, show the apparent paths of Venus as seen at the two stations. The length of the line W H is the "parallax" of Venus, or the amount of apparent displacement suffered by that planet from being seen from widely separated points. The length of this line can be readily computed. The rate of movement of Venus in transit is known with great precision, and when, from observation, the instant of ingress or egress of the centre of the planet is known, the time of her describing the chords *a c* and *b d* becomes known, and from that the *length* of those cords. Thus, if the rate of motion be 4′ 3.5″ per hour, and the time be 5h. 42m., or 5.7h., the chord *a c* must be 5.7 times 4′ 3.5″, or 23′ 7.95″ long; in a similar manner the length of the other chord, *b d*, becomes known. The angular radius (apparent semi-diameter) of the sun being known, say 14′ 55.8″, at that time, and taken = 1, then half of the chord *a c* or W *c* would be .7747. Now C *c* = 1, from which take the square of .7747 and extract the square-root of the remainder, and the result will be .63233, the length of C W. By proceeding in a similar manner with the radius C *d* and the half-

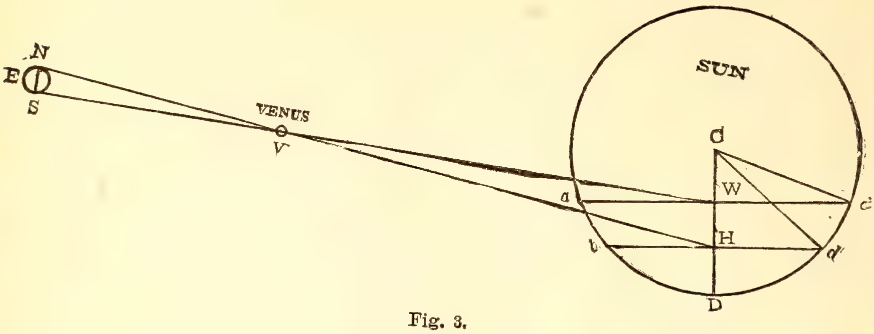

Fig. 3.

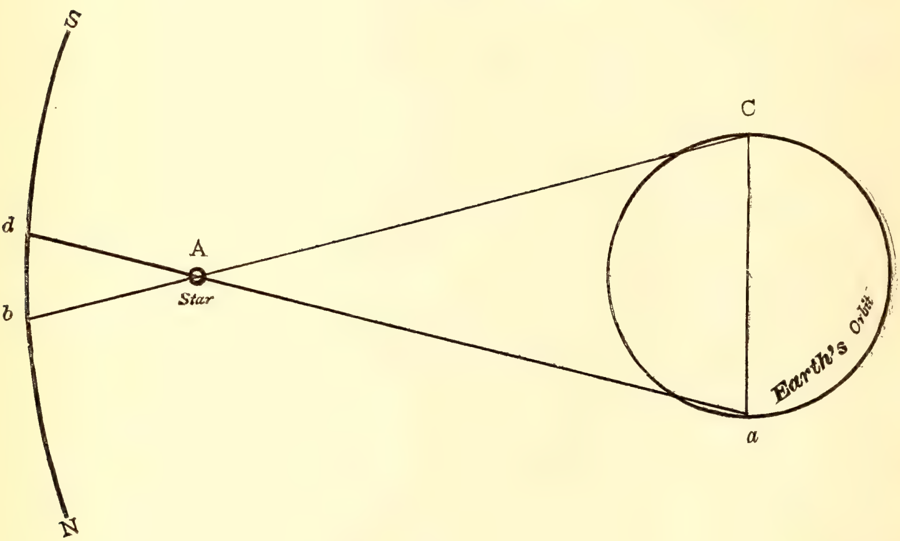

Fig. 4.

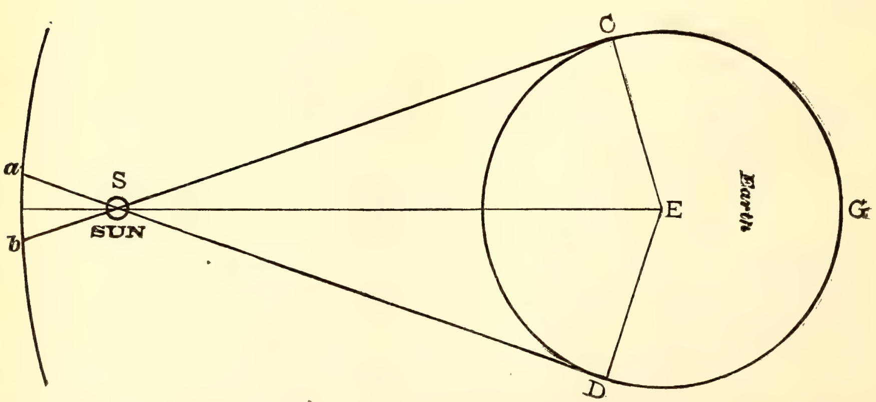

Fig. 5.

chord H *d*, the length of C H becomes known. From C H subtract C W, and we have W H, which is really the object sought, and is the parallax of Venus. "But this is not the parallax of the *sun.*" True, but the parallax of the sun is obtainable from it.

It is known that the distance of Venus from the sun is 72-100 of the earth's distance. Now let the earth's distance be represented by 100, then Venus' distance from the sun would be 72, and her distance from the earth 28. Now, as the ratio of the parallaxes varies inversely as the distances of the bodies, the parallax of the sun can be ascertained by the following proportion: E V : V W : : N S : (?) or, calling the earth's *radius* 1, we have 28 : 72 : : 2 : (5), or as 1 is to 2½. In place of N S the actual distance between the two observers will be substituted, which is their difference of latitude. In other words, this proportion shows us that the displacement (parallax) of Venus is 2½ times less when viewed from the points N and S in Fig. 3, than if viewed from the distance of Venus. But the sun's *horizontal* parallax, the amount of displacement suffered by the sun when seen from the *centre* and circumference of the earth, must be still half of this or one-fifth of the parallax of Venus. Suppose the arc W H = 42.8″, then must the sun's horizontal parallax be 8.56″. The correctness of this method depends upon the accuracy with which the angles are taken, but it will be seen that any error of observation is reduced five times in the final result. The extreme delicacy of the operations required may be judged from the fact that the difference between the old parallax (8.73″) and the latest (8.82″) or .09″, is equivalent to about 1,000,000 miles, and this arc (0.09″) is no greater than would be the apparent thickness of a human hair viewed at a distance of 100 feet. Notwithstanding the apparent insignificance of the figures, the latter estimate adds many millions of cubic miles to the calculated volume of the sun and many times the earth's mass to its weight; changes the estimated distances, volumes, masses, and diameters of all the other planets. A still greater error is made in computing the distances of the fixed stars. The earth's distance from the sun is used as a base line to compute the distance of the stars. Thus, in Fig. 4, which, of course, is not drawn to scale, the better to illustrate, when the earth is at *a* in its orbit a certain star (A) is observed to be at *d* in the heavens S N, and six months from the date of the first observation, when the earth is at C, the same star appears at *b*. Now it is a fact that the nearest fixed star shows *no* displacement when viewed from *c* and *a*, 184,000,000 miles apart. But nevertheless this method is used indirectly to ascertain the depths of stellar space, and the distances of over a dozen stars is known; and hence it is that this minute error in the sun's parallax of .09″ will produce an *error* of 200,000,000,000 miles in the calculated distance of the *nearest* fixed star, and in some whose distances have been computed this error would be increased *fivefold!*

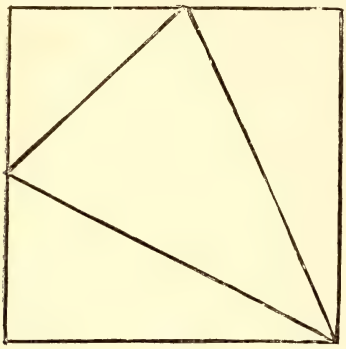
"But how do you find the sun's distance from the earth from the horizontal parallax?"

In Fig. 5 let C D G represent the earth and S the sun; then, according to what we have already shown, the sun's horizontal parallax is the angle E S D or E S C, or, in other words, the *earth's apparent semi-diameter*, E D or C E, as *seen from the sun.* Then, in the right-angled triangle E D S, we have given the angle E S D and the side E D, to determine the hypotheneuse, E S, or the sun's distance, one of the simplest problems of plane trigonometry. The earth's radius, divided by the sine of the sun's horizontal parallax = the distance sought. Thus we find, by using a parallax of 8.82″, that the sun's distance is 23409.4 times the earth's radius, or 92,759,700 miles distant.

—M. Tissandier, the French aeronaut, has devised an elliptical balloon, which is to be driven by a dynamo machine and storage batteries. The balloon will be 131 feet long, and will have a capacity of more than 100,000 cubic feet, with a lifting power of 3½ tons, which will allow for a ton of passengers and ballast. It does not require much knowledge to see that such a machine must prove a failure.

Solution of the Mathematical Puzzle.

LAST month we gave a mathematical puzzle, of which we now give the solution. No explanation is necessary as the engraving tells the whole story. Place the pieces



MATHEMATICAL PUZZLE.

shown on page 13 of our last issue in the relative positions which they have in the figure now given and the thing is done.

Our Girl's Department.

This department is intended exclusively for "Our Girls," and we hope to make it both interesting and instructive, and to this end we ask our young lady readers to assist by contributions, suggestions, or illustrations. There are thousands of little things that can be, and have been, made and done by young ladies, pertaining to decorative art, needle-work, etc., etc., that would be gladly followed but for a want of knowledge on the subject, and we know of no more pleasing task for a lady than that of teaching her younger sisters that which they are anxious to learn, and which may prove of real benefit to them in the future, as well as being useful and interesting for the present. We trust we will have no difficulty in persuading those who have something nice to show or speak of, to make use of this department. Remember, it is open to all, and if you have anything worth knowing suitable for this column, send it along, and we will give it our best attention. Do not be afraid to write because you may fancy your composition is not perfect, or have other scruples of a similar kind. Do the best you can, and leave the rest to the editor of this department, and we are sure you will be pleased with your work.

GOOD manners is the art of making those people easy with whom we converse. Whoever makes the fewest persons uneasy is the best bred in the company.

— The greatest friend of Truth is Time; her greatest enemy is Prejudice; and her constant companion is Humility.

— The most delicate and the most sensible of all pleasures consists in promoting the pleasures of others.—*La Bruyere.*

— If you have two topics to talk to a friend about, one of which interests her the most, while the other interests you the most, begin with that which interests her the most. It will put her in good humor; it will confer pleasure.—*Bentham.*

— The true art of being agreeable is to appear well pleased with all the company, and rather to seem well entertained with them than to bring entertainment to them. A woman thus disposed, perhaps, may not have much learning or any wit, but if she has common sense and something friendly in her behavior, it conciliates people's minds more than the brightest parts without this disposition. It is true, indeed, that we should not dissemble and flatter in company, but one may be very agreeable, strictly consistent with truth and sincerity, by a prudent silence where she cannot concur, and a pleasing assent where she can. Now and then you meet with one so exactly formed to please that she will gain upon every one that hears or beholds her. This disposition is not merely the gift of nature, but frequently the effect of much knowledge of the world and a command over the passions.—*Addison.*

— Sea fern makes a particularly effective design for any purpose where a continuous stripe is necessary. It is easy to work, and, if carried out in the pale green tints of the natural weed, will harmonize with anything.

— Wall pockets are made of cardboard covered with embossed velvet, each flower in the pattern of the material being outlined in pearl or incandescent beads. Cord of the same color as the velvet is used to finish them off.

— A very good idea for the brightening up of a nursery or play-room consists in decorating the panels of the doors by the insertion of brightly colored lithographs, fitting them into the panels and framing them, if necessary, with a narrow beading of gilding. Most of our young lady readers possess taste enough to successfully perform this kind of work. When

neatly done, the result will be pleasing and satisfactory.

— An inexpensive winter plaque is oval-shaped and painted on wood. It represents two brown owls perched on the broken branch of a tree in a snow-storm, while one of them is gallantly holding an umbrella to shield his companion from the falling flakes. There is no brilliant coloring in this to cover up defects, and, to look well, the design must be executed with skill; then it is both pretty and odd.

— A speck of embroidered work, worth $60, to be applied to a chair seat, is but a drop in the ocean of decorative splendor.

— A scrap-basket formed of a small Japanese umbrella is a novel and pretty article shown at the New York Exchange for Women's Work. This is mounted on a six-inch stand of cherrywood, with point downward and the frame half expanded, and kept in this position by being wound around each rib by a silken cord passed from one to another near the top. Silk balls of different colors hang from all the points where the sticks are wound, and the handle is ornamented by a bow of pink and blue ribbon combined.

— Katie B—— sends us her thanks for presenting her communication of last month in such a readable form. She says: "Many handsome things, suitable for the house may be made from some of the cheapest of materials. I have made several covers for bureaus and toilet stands, of crash. Designs of leaves, flowers, twigs or fruit may be used and worked in generally with linen floss. Covers or tidies made of these materials have much to recommend them, as they can be washed whenever required, and do not lose any of their beauty by the operation. The work is generally made solid, and finished off by an insertion of drawn work and fringe. For furnishing bureau sets it has become quite fashionable of late to use etched linen, the favorite design being a thistle and bud, the full blown flower rising above the latter. Usually they are finished of with bows and ends of light colored satin ribbon."

— At a "Studio Tea" given in the large class-room of the "Ladies Art Association Studio Building," in Fourteenth street, New York City, tea was served by a company of young girls in picturesque costumes. The decorations of the large class-room and the studios, all of which were thrown open, were of a symbolic character; easels decorated with the leaves of the red oak, stood for artistic strength; busts garlanded with rosemary for thought; paintings framed in laurel and ivy, and a ladder of evergreens, painted palettes and pictures displayed on carved easels, were among the attractions of the occasion. The window draperies hanging by brass rings from maul-stick rods with a small palette for ornamental end; dadoes of burlaps tacked to a narrow moulding, and headed by a narrow band of garnet cloth, and the walls of a studio painted with trunks of forest trees spreading branches over windows and doors, and wall hangings for picture backgrounds, offered valuable hints for house decorations. The tables, about twenty in number, were laid in old style, old-fashioned homespun linen, prettily associated with color; ancient silver urns on Dutch tiles and brass tea kettles sending forth wreaths of fragrant steam; quaint American porcelain from the only hard porcelain pottery in the United States, and the qaintest of old-fashioned chintz covered chairs, with the bevy of rustic artist attendants, completed a pretty picture.

INGENIOUS HOME-MADE PICTURE CARDS.

A great deal of ingenuity has been recently developed owing to the steady and increasing demand for novelties in picture cards. This being the case many very amusing and also truly artistic combinations of natural materials have appeared in the hands of the large dealers of cards in New York City. I have selected one of the most unique, comical, and at the same time most easily made, as the materials are always obtainable. The two owls consist of *single kerneled* peanuts that have just a suggestion of a stem attached to them. This stem is intended to form the beak of the owls, yet it is not

absolutely necessary that the peanut should have the stem, as very good peanut owls can be made without it. Each peanut is cut away one-third with a very sharp knife or razor, and the kernel is taken out. The eyes can be cut out of stiff white paper with a punch. All harness makers use a punch just about the size required. Or they can be drawn in with a pen and the whites painted with a brush. The card used for mounting is a stiff white, gilt edged, plain card, 4½ inches by 3 inches. Much taste can be displayed when selecting the branch work that is to represent the tree on which the owls are to be placed. Always select small, not large clumsy branches. A branch of the liquid amber gum tree (called also the "alligator wood," "cork tree," etc.), with its characteristic structure will look much better than the smooth barked birches. For the foliage, any of our native mosses and lichens can be used, and also the imported French and German mosses. When attaching the tree to the card, don't attempt to glue it, but sew it on, or wire it on with fine thread or wire, and fasten at the back of the card. After the tree is secured in position on the card the moss foliage is then glued or gummed on (thick and transparent gum arabic is better than glue as it does not show where an excess has been used). After the gum has thoroughly dried the owls are glued in position. As to the title, motto, or sentiment, each one can suit herself. As novelties in this line appear in the New York market they will be illustrated in the YOUNG SCIENTIST, and directions given for making them.

THE

Young Scientist.

A Practical Journal for Amateurs.

(With which is incorporated "THE TECHNOLOGIST," "THE INDUSTRIAL MONTHLY," and "HOME ARTS.")

PUBLISHED MONTHLY AT $1.00 *PER YEAR.*

EDITORS.

JOHN PHIN. FRED. T. HODGSON.

Published by

THE INDUSTRIAL PUBLICATION CO., 49 Maiden Lane, New York.

Will those of our subscribers who receive two copies of the YOUNG SCIENTIST, kindly hand the duplicate to some friend interested in such matters, and thus perhaps aid us in securing a new subscriber? Remember that every additional name enables us to improve the Journal, so that all have an interest in adding to the number of our subscribers.

Of course, it is always in order to subscribe for the YOUNG SCIENTIST, but when possible we would prefer that subscriptions commence with the first number of one or other of the volumes. This course will be more satisfactory to the reader, and will also make things pleasanter for the publisher, as it will lessen the labors of bookkeeping and smooth matters all round. And as a further inducement to this, we would say that we always try to make *continued* articles end with the volume, though sometimes, of course, it is impossible to do this.

The expeditions organized by the British for the purpose of observing the transit of Venus have been generally successful at all stations, with the exception of Brisbane. The Madagascar party have been very fortunate in their observations. The interval between the contacts at ingress, as observed at Madagascar and Bermuda, is about thirteen minutes. The ingress observations at the West Indies, combined with those of the Cape of Good Hope, will supply the means of making one good determination of the sun's distance; while the egress observations of the West, combined with those made in New Zealand, will furnish another.

Nothing will give us greater pleasure than to have our young readers write us freely on any matter connected with amateur science or mechanics, with a view to obtaining information on the subjects they may be working at. We cannot promise that in every case we shall be able to give the answer desired, but we can safely promise that in a large majority of cases we shall be able to materially aid the inquirers in their labors, and thus lead them on to the accomplishment of their objects. Much good may be done by asking for information through these columns, as many readers other than the inquirers may want to get the same information, but are, from many causes, deterred from writing. A postal-card, in most cases, will be quite ample for the purpose, but where it is not, letter postage does not prove very expensive, and is equally acceptable to us.

Those who, prior to the issue of this number, have sent fifty cents in the hope of receiving the YOUNG SCIENTIST for the whole of 1883, will not be disappointed. We shall send it to them even at a loss. But we have no hesitation in asking them to show the Journal to some friend, and thus secure another subscriber for us at $1.00. After the issue of the February number those who send fifty cents will receive the YOUNG SCIENTIST for six months only. We make them this liberal offer, however: Where we are satisfied that the fifty cents was sent in good faith, under the idea that the subscription to the Journal was that amount, we will send the YOUNG SCIENTIST for the whole year, if the sender will secure another sub-

scriber at one dollar. With such a journal as we are now giving, it ought to be no trouble at all to induce some friend to subscribe.

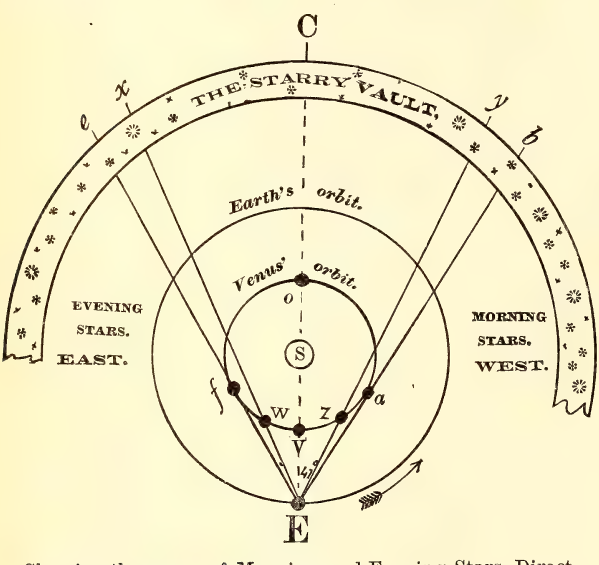
It is often amusing to read some of the articles said to be "scientific," that appear from time to time in our trade and other papers. Indeed, it seems to be the fashion now-a-days for every newspaper man to devote so much space daily, weekly or monthly, as the case may be, to scientific articles and instruction; and it frequently happens that the writer knows as much about the matter he writes of as he does about the anatomy of the man in the moon. Directions are frequently given for the performance of experiments and operations, which, if attempted to be followed, would surely end in disappointment, and often with injury to the operator; more particularly is this the case when chemical or electrical experiments are described; and we advise our readers to make sure of the correctness of the description and the innocence of the results before undertaking to follow the instructions. Of course, this only refers to those papers that make no pretentions to being scientific, but which seem to think it a duty to "dabble" occasionally in science. Most of these papers are good enough in their place, and are no doubt performing a useful mission, but it would be better for them and their readers if they followed the old proverb, "Let the cobbler stick to his last," and we are sure science would not be the loser under the condition.

The Planets.

FEBRUARY, 1883.

(All Computations are for the Latitude and Meridian of New York City.)

Venus.—The "Queen of Beauty," will continue to maintain her supremacy as the most brilliant star in the east in the morning throughout this month. She is now approaching a point in her orbit where her daily motion in right ascension is very much less than last month, and near the middle of next month she will be "stationary," as astronomers say; that is, she will *appear* to move neither east nor west. This, and the different kinds of apparent motion, can best be illustrated by the annexed diagram.



Showing the cause of Morning and Evening Stars, Direct and Retrograde Motion. The earth is supposed at rest at E during a revolution of Venus.

Suppose the earth at rest at E, and Venus at V. Then Venus will be nearest the earth, or between the earth and sun, and when first seen she will be just to the right or west of the Sun. When at *z* she will appear to be at *y*, and later, when at *a*, at *b*. This last space, from *y* to *b*, occupies just as much time as from C to *y*, the spaces V *z* and *z a* being equal. Her path from *z* to *a* being nearly in a line from the earth, causes her slight apparent motion. When at *a*, Venus is said to be at greatest elongation west. That is, the angle S E *a* can never be larger than when Venus is at *a*, making an angle at E of 47°. As she is then west of the Sun, she must of course rise before the Sun, and is therefore a morning star. She will appear largest, or have the greatest apparent diameter, when at *v*, but will not then be brightest as her unilluminated side is toward us. As she passes westward, a small edge of her illuminated side becomes visible as a silver thread of light or slender crescent; this increases as she approaches *a*, where one-

half of her illuminated hemisphere is seen by us as a half-moon phase; she is brightest, however, about 33 days before she reaches a. When Venus passes the point o of superior conjunction, where she appears as a miniature full moon, she will be seen east of the Sun, and must, therefore, set after the Sun, and is an evening star. From o to f her apparent motion is direct; at f she again becomes stationary, and from there to v her apparent motion is retrograde or backwards in the heavens. The amount of retrogradation is greatly exaggerated by supposing the earth at rest.

Venus rises on the 15th at 4h. 13m. morning, appearing as a small half-moon when seen in the telescope. New evidence of an atmosphere upon this planet was discovered at the recent transit.

Mars rises at 6h. 19m. morn., Feb. 15th.

Jupiter maintains about the same place as given last month, being stationary on the 15th. The Moon will be 2½° south of him on the 16th, and he passes the meridian on the 10th at 8 o'clock in the evening; 25th, at 7 P.M. Eclipses of his satellites may be seen in the evenings as follows (R. being for reappearance, and D. for disappearance. See note last month): Feb. 2, 6.56 R.; 3d, 7.39 R.; 9th, 9.31 R.; 10th, 9.34 R; 16th, 6.58 R.; 23d, 8.18 D.; 26th, 7.55 R. The transits transpiring in the early evening are: 2d, 7.12 Ingress, 9.29 Egress; 5th, 8.43 Eg.; 9th, 9.1 In.; 18th, 7.35 Eg.; 25th, 6.47 Eg. Occultations: 16th, 7.2 Dis.; 17th, 8.4 Dis.

Saturn is at eastern quadrature, or 90° east of the Sun on the 8th, and 1½ degrees south of the Moon on the 13th. He passes the meridian on the 10th at 5.49 P.M., and 25th at 4.53 P.M. The most distant and largest of his satellites, Japetus, is quite easily seen in small telescopes. This satellite will be at greatest eastern elongation Feb. 16th. The next in size, Titan, can be easily seen at the present time, being at western elongation on the 9th and 25th, and at eastern elongation on the 1st and 17th.

Uranus will be brightest March 12th, and may be readily seen with opera-glasses during February. He rises as follows: 10th, 8.1 eve.; 25th, 6.55 eve.; being about 2° S. of the 3d Mag. Star Beta Leonis, midway between Regulus and Spica.

EPHEMERIDES OF THE PRINCIPAL STARS AND CLUSTERS, FEB. 20, 1883.

	H.	M.
Alpha Andromeda (Alpheratz) sets	9	51 P.M.

Penn Yan, Yates Co., N. Y.

The Tower of Nanking.

The celebrated porcelain tower, near Nanking, China, must have been very beautiful in its perfection, if we accept the statements of its various historians, who differ so little in their accounts that one does for all. From them we learn its form was octagonal, nine stories high, tapering as it rose to the height of 261 feet from the ground, the circumference of the lower story being 120 feet. The body of the pagoda was of brick, but its face was composed of porcelain tiles of many colors. Each story formed a kind of saloon, through which ran the spiral stair-case leading to the summit, and whose walls were covered with small gilded idols resting in niches, the entire apartment richly painted and gilded. Each story was defined by a projecting cornice of green tiles, from whose points gilded bells were hung. The roof was overlaid with copper, and above it rose a mast thirty feet high, capped by a golden ball and coiled about by an immense band of iron, appearing like rings from below. The base of this shaft was an iron ball formed of two halves, the outer surface of which is still magnificiently embossed, for one half rests where it fell, the only tangible thing in the mass of ruin. The other half, weighing twelve tons, being broken by the fall, was recast into a temple bell. Who were they that fashioned this beautiful casting, worthy the hand of a master? Whose writing and inscription embellished its face, unlike any Chinese workmanship? Whose skill was great enough in A.D. 1330 to place a ball of iron thirty-six feet in circumference, weighing twenty-four tons, upon a pedestal 261 feet high? This ball was the receptacle for various treasures calculated to ward off evil in-

fluences, among which were "night-shining jewels," pearls, books, gold, silver, thousands of strings of cash, satin, silk, and priceless medicines. The number of bells on the structure was 152, and the interior was illuminated by hundreds of lamps, while the exterior required 128 to light it. It took nineteen years to build it, and cost nearly a million of money. Of all this not one story rests upon the other. Lightning, fire, and war have laid their hands upon it, and it fell, its final destroyers being the Taeping rebels, some twenty-three years ago. It stood in the grounds of a Buddhist monastery which fell at the same time a prey to the fanaticism and rapacity of the invaders. One work of art within the grounds escaped destruction–a pure white marble tortoise, bearing upon its back a perpendicular tablet with an inscription. This with one solitary priest keeps watch and ward over the ruins of bygone glory.

Skilled Workmen of Other Days.

In the twentieth year of Queen Elizabeth, a blacksmith named Mark Scaliot made a lock, consisting of eleven pieces of iron, steel and brass, all of which, together with a key to it, weighed but one grain of gold. He also made a chain of gold, consisting of forty-three links, and, having fastened this to the before-mentioned lock and key, he put the chain about the neck of a flea, which drew them all with ease. All these together, lock and key, chain and flea, weighed only one grain and a half. Oswaldus Norhingerus, who was more famous even than Scaliot for his minute contrivances, is said to have made sixteen hundred dishes of turned ivory, all perfect and complete in every part, yet so small, thin and slender, that all of them were included at once in a cup turned out of a peppercorn of the common size. They were almost invisible to the eye. An artist named Claudius Gallus made for Hippolytus d'Este, Cardinal of Ferrara, representations of sundry birds sitting on the tops of trees, which, by hydraulic art and secret conveyance of water through the trunks and branches of the trees, were made to sing and clap their wings; but at the sudden appearance of an owl out of a bush of the same artifice, they immediately became all mute and silent.

The Mechanical Boy.

The mechanical boy should have a shop of his own. Let it be the attic, or an unused room, or a place in the barn or the woodshed. Give him a place and tools. Let him have a good pocket-knife, a gimlet, chisels, gouges, planes, cutting nippers, a foot-rule, saws, and materials to work. Let the boy have a chance. If he is a mechanic it will come out, and he will do himself credit. If he fails, he is to follow some calling that does not demand mechanical skill. With a foot-rule in his pocket, the boy will be continually measuring. Before he is aware of it, his eye will be educated to judge of dimensions and proportions. It is a good substratum on which to erect the knowledge of practical mechanics. Acquired as an amusement, this knowledge will become practically useful as the boy develops into the man. The employments suggested by the pocket-knife and rule will occupy many an otherwise idle hour, and afford a pleasant relief to the routine of school study and the weariness of oft-played games. The boy will become acquainted practically with substances, and be interested in the mechanical operations he witnesses, and this will pave the way for his easy entrance on the vast field of useful endeavor before him. He will become an intelligent and willing apprentice, and a judicious and skillful workman. Give the boy a chance.

The Oldest Newspaper.

The oldest newspaper in the world is the *King-Pau*, or "Capital Sheet," published in Pekin. It first appeared A.D. 911, but was irregular in its issues until 1351. Since then it has been published weekly until the fourth day of June last, when by order of the reigning Emperor it was converted into a daily, with three editions, morning, midday, and evening. The first edition appears early and is printed on yellow paper. This issue is called *Hsing-Pau* ("Business Sheet"), and contains trade prices, exchange quotations, and all manner of commercial intelligence. Its circulation is a little over 8,000. The second edition, which comes out during the forenoon, also printed on yellow paper, is devoted to official announcements, fashionable intelligence, and general news. Besides its ancient title of *King Pau* it owns another designation, that of *Shuen-Pau*, or "Official Sheet." The third edition appears late in the afternoon, is printed on red paper, and bears the name of *Tilani-Pau*, "Country Sheet." It consists of extracts from the earlier editions, and is largely subscribed for in the Provinces. All three issues of the *King Pau* are edited by six members of the Han-Lin Academy of Science, appointed and salaried by the Chinese State. The total number of copies printed daily varies between 13,000 and 14,000.

A New Puzzle for Young Folks.

Since the ingenuity and mathematical skill of the whole country were so severely taxed by the fifteen puzzle, with its curious and perplexing combinations, there has been a flood of similar contrivances, which have excited more or less interest, but all have fallen far short of the success attained by the pioneer in that line of amusement. The latest invention is the Nine-Letter Puzzle, and it bids fair to rival in difficulties the best of those that have gone before. The inventor, Mr. Sidney A. Phillips, as long ago as the winter of 1880, had perfected the combination of letters essential to the completeness of his puzzle, but he was only recently prevailed upon by his friends to have it copyrighted. The following diagram will convey an accurate idea of the arrangement of this puzzle:

P	L	O
C	I	A
D	Y	R

Each one of the nine letters above is printed on a small square block of wood, and to solve the puzzle it is necessary so to arrange these letters that they will form one complete square, having three letters on each side, and while constituting such a square the nine letters must also form eight different and distinct English words that can be found in a standard dictionary. These words cannot, of course, contain more than three nor less than two letters, and they must not read from the right to the left. The combinations must be made from top to bottom, vertically; from left to right horizontally, and from left to right diagonally.

For example, using the letters as they are printed in the diagram above, without any intention of spelling actual words, the following would be legitimate combinations: PLO, CIA, DYR, PCD, LIY, OAR, PIR, DIO, LA, CL, CY, YA, making in all only twelve possible combinations under the rules governing the solution of the puzzle. RIP, OLP, AY and others made from the right would not be allowable.

It can readily be seen that the solution of this puzzle under these conditions must be attended by no inconsiderable difficulties, and as the difficulties it presents can safely be taken as a measure of the success a puzzle will have, it does not seem rash to predict that the nine-letter puzzle will arouse no little interest.

In conversing about the obstacles he has had to overcome before reaching this final combination of letters, the inventor said that he devoted four months to the perfection of his plan. At first he tried but six letters, and then eight, and even when he had settled upon nine as the proper number, it seemed to him that five was as large a number of words as could be formed out of them. At last he struck upon the nine letters that constitute his puzzle, and is convinced by his numerous experiments and the efforts made by friends to solve it, that it is the most complete set possible.

One solution that has several times been reached contains seven words, and falls one short of the requisite number by an infringement of the rules governing the puzzle. After the seventh word there is something very like a big "if" left, which may or may not be construed into a hint.

A Lamprey's Nest.

One day late in spring, as I was passing over a bridge, I chanced to see two lampreys, or "lamper-eels," as they are usually called, engaged in building their nest in the creek below me. It was one of the most curious spectacles I ever saw in our stream. They were a few yards below the bridge, just where the water breaks from the still pool beneath it, and flows with a rapid current over its roughly paved bottom. They were distinguishable from the yellowish brown and black stones and pebbles amid which they were working only by their motions. They were tugging away at the small movable stones with great persistence. I went down to the water's edge where they were within the reach of my staff, the better to observe them. They would run up to the edge of the still water and seize upon the stones with their suction mouth and drag them back with the current and drop them upon their nest. I understood at once why their nests, which I had often observed before, were always placed at the beginning of a rift; it is that the fish may avail themselves of the current in building them. The water sweeps them back with the pebble in their mouth, their only effort being in stemming the current to seize it. They are thus enabled to move stones which they could not stir in still water.

The stones varied in size from a walnut to a goose egg. When one of them was tugging away at a stone too heavy for it, I would lend a helping hand with my staff; I would move the stone along gently, and the lamprey seemed

entirely unconscious of the fact that it was being helped; it would drop the burden at the proper point, and run up for another. Indeed my aid and presence did not disturb them at all. From time to time, the larger of the two, which was the female, would thrust her tail with great violence down among the pebbles at the bottom of the creek and loosen them up, and set free the mud which the current quickly carried away. The new material thus plowed up was carried to the nest. Twice in the course of the half hour that I observed them, the act of spawning took place.

Besides helping move the larger stones with my staff, I several times plowed up the bottom with its point, thus relieving the female of that duty. The fish took it all as a matter of course, and seized upon the pebbles I had loosened with great alacrity. When I thrust my cane beneath them and tried to lift them out of the water, they would suck fast to the stones and prevent me; but they did not manifest any alarm. The lampreys become much exhausted with the spawning and nest building, and large numbers of them die when it is over. In June it is not unusual to find their dead bodies in the streams they inhabit.—*Century.*

Our Book Table.

Poultry Diseases: Their Prevention and Cure. By H. H. Stoddard, Editor of *The Poultry World,* author of "An Egg Farm," etc., etc. Price, 25 cents. Hartford, Conn.

This little work is by a practical man, and we have been very much pleased with its directness and simplicity. While it is true in the case of poultry, as of all pets, that cleanliness, good feed and attention to the ordinary rules of hygiene are worth all the drug stores on the Continent, still it is also true that, in spite of these, occasionally a valuable fowl will show symptoms of disease, which, if taken in time, may be cured. As for common fowls, it hardly pays to fuss with them; when they are sick, separate them from the rest of the yard, give them proper food and quietness, and in many cases they will get well. If they die of disease, be sure to either burn or boil them thoroughly, if the disease is of a malignant character. Burying is not safe, even at six feet, for the miserable earth-worm will go down, bring up the germs of disease to the surface, and then, when eaten by the other fowls, they will infect the whole flock.

We are glad to see that Mr. Stoddard places special stress on the necessity for prevention, and lays down simple and accurate rules on the subject.

Scientific Proceedings of the Ohio Mechanics' Institute.

In addition to the regular proceedings, this volume contains valuable papers on Pumping Engines for Public Water Supply, by John W. Hill, M.E.; Comparative Economy Tests of the Gearing Boiler Furnace, by John W. Hill. M.E.; Average Weights of Men and Women, by W. A. Collord; A Criterion for the Measurement of the Speed of Chemical Action, by Robt. B. Warder; Urech's Investigation of the Speed of Inversion of Cane-Sugar, by Robt. B. Warder; The Aurora Borealis of April 27, 1882, by Chas. G. Boerner. The publication is a great credit to the Institute of our sister city. Unfortunately the Institute of similar constitution in New York (The American) publishes no proceedings of its own, and no author of a valuable paper would read such before it, because his doing so would simply prevent recognition elsewhere, and would thus result in burying it.

Correspondence.

A Cheap Battery.

Ed. Young Scientist—I have found that by taking a common fruit can and filling it about three-quarters full of a saturated solution of common salt, and then putting about a tablespoonful of salt in the bottom, so as to keep the solution saturated, placing upon this a piece of any kind of paper, and then laying upon the paper a piece of common coke, taking care that the coke does not touch the can at any point, and then attaching a wire to the can and another to the coke, quite a constant though weak battery is obtained. I have one that has been in constant use for over a week, the circuit being kept complete all the time. With four cells you can decompose acidulated water, salt and water, etc.; also deflect the needle of a galvanometer very readily, and try a number of very interesting experiments. The cost of the battery is very little, being from a cent to two cents a month at the outside.

W. C. Foster.

Scientific News.

—Gen. W. H. Hazen, of the Signal Office, invites people to send him all sorts of popular weather proverbs and prognostications.

—There have been set up in the Grand Opera House at Paris a number of mirrors, measuring 45x52 ft., and weighing from 1,200 to 1,600 lbs.

—The Washington monument is fast getting to be a big thing. It is now over 300 feet high. When completed it will be the highest piece of architectural work in the world.

—A French chemist has analyzed the juice of the so-called milk tree of Central America, to the

nutritive qualities of which attention was first drawn by Humboldt, and has found that the vegetable product really possesses many of the characteristics of cow's milk.

—Eighteen young ladies who graduated at the Boston Institute of Technology last year have found lucrative positions as designers in chintz, calico, wall paper or floor coverings.

—Those who yet cling to the old-time faith in the moon's influence upon the weather may be interested to learn that so eminent a scientist as Sir William Thomson has recently felt called upon to declare that careful observation with the barometer, thermometer and anemometer have failed to establish any such influence, and have proved, on the contrary, that if there is any dependence of the weather upon the phases of the moon it is only in a degree so slight as to be quite imperceptible to ordinary observation.

—A mining superintendent at the West says that by the use of the chronograph he ascertained the fact that the long pump-bobs in his mine moved down at the top before they stopped coming up at the bottom—that is, they went both ways at once. This seems absurd, but is rational, for the pump-bob being 3,500 ft. long, and made of wood, some time elapses before motion at one end is transmitted through to the other. It would be interesting to know exactly where the neutral point is.—*Mechanical Engineer.*

—Mr. Jardine, M.P., has recently had erected in the grounds at Castlemilk, England, a sun dial of extraordinary dimensions. It consists of a large twenty triangular-sided stone, supported on a pedestal thirteen feet high, and is after the style of Queen Mary's dial in Holyrood grounds. There are fifteen dials. Two indicate Greenwich time, two tell the time of night by the moon; the others indicate the rising and setting of the sun, the length of the day, tell when it is noon at the principal places over the globe, the sun's declination, etc.

—Prof. M. W. Harrington refers to two kinds of changes on the moon's surface which may be regarded as fairly established. The first is the land slides, which may doubtless be caused by the great alterations of temperature to which the moon is subject. Many of these slides may be easily recognized with good telescopes. The second form of change is illustrated by craters, which have been proven to be different in size and shape from what they were recorded by earlier observers. Many other changes have been suspected, but they are of a more uncertain and doubtful character.

—The Editors of *The American Naturalist* desire information as to whether honey or other bees are carnivorous, and publish some notes showing that they lap the juice of fresh meat. In this country at least, one, if not several, honey bees have been noticed by a reliable observer resting on a piece of meat in a butcher's shop in Providence, R. I., and lapping with their mouth-parts the fresh meat, apparently feeding upon the juice of the beef. Dr. H. Mueller also contributes to the same magazine his brother's (Fritz Mueller) observations on carnivorous bees, and shows that not only wasps, but also numerous honey and wild stingless Brazilian bees, species of Melipona and Trigona, have been observed by him in Brazil. Any information of a similar nature, if carefully made, is desired. It is possible that bees may not actually eat raw flesh, though wasps are known to do so, but simply visit exposed meat to sip the sweet juice, just as butterflies are known to be attracted by decaying fish, and lap or suck in the fluid standing on the fish.

Practical Hints.

Red Ants.—The judicious use of oil of turpentine will effectually exterminate red ants. It may be injected into cracks and crevices in closets and elsewhere from an ordinary sewing machine oil can.

Preservation of Game.—*Forest and Stream* gives sportsmen this advice: "Kill the owls; kill the hawks; kill the foxes; kill the skunks; kill the red squirrels. Remember that this destruction of vermin means something toward the preservation of the game supply."

Frosting Brass Work.—The *English Mechanic* gives this formula for frosting brass work to give it an ornamental finish: "Boil in caustic potash, rinse in clean water, and dip in nitric acid till all oxide is removed; then wash quickly, dry in boxwood sawdust, and lacquer while warm."

Stove Blacking.—It is said that the most lasting polish is obtained by first brushing the stove with a syrupy mixture of lampblack and soluble glass, and letting dry for twenty-four hours. Then apply a syrupy mixture of blacklead and mucilage, and polish by brushing before the last coat dries.

Black Leather-Varnish.—A black leather-varnish, which is said not to crack or peel off, may be prepared thus: Rosin, 30 parts; turpentine, 30 parts; oil of turpentine, 30 parts; sandarac, 60 parts; shellac, 120 parts; alcohol (90 per cent.), 900 parts. Digest, then add lampblack, 15 parts, previously triturated with a little alcohol.

Salicylic Acid in Wooden Vessels.—The preservative and antiseptic action of salicylic acid cannot be relied on when brought into contact with any liquid substance in wooden vessels or casks. The salicylic acid under these circumstances speedily disappears, being apparently absorbed and decomposed by the wood tissue. When this acid is used as an addition to drinking

water or wine, the cask must first be coated with pitch.

Restoring Frozen People.—Medical men have always differed as to whether the best treatment of frozen persons was by a gradual or rapid application of heat. To settle the matter, Laptchinski has made a series of very careful experiments upon dogs, with the following results: Of twenty animals treated by the method of gradual resuscitation in a cold room, fourteen perished; of twenty placed at once in a warm apartment, eight died; while of twenty immediately put into a hot bath, all recovered.

Hard Putty.—The *Carriage Monthly* gives the following for a hard putty that will dry in one day: Take the whitening, mash all the lumps out on the stone, and mix into a stiff paste by adding equal parts of japan and rubbing varnish; then add as much keg-lead as you think will make it work free with the knife; then add the rest of the whitening until you have it to suit you. This will sand-paper good with one day's drying. If you want putty that will dry quicker, take dry white lead and mix with equal parts of japan and varnish, to which add a few drops of turpentine. This is very soft for puttying, but can be sand-papered in from two to three hours, it becoming perfectly hard in that time.

Label Varnish.—An excellent varnish, which dries in a few seconds, and produces a colorless, smooth, and shining coat, is prepared, according to R. Kirsten, from the following:

Sandarac	53
Mastic	20
Camphor	1
Oil of lavender	8
Venice turpentine	4
Ether	6
Alcohol	40

The ingredients must be macerated for weeks, until everything is dissolved. It is, therefore, advisable to prepare a sufficient quantity to last for some time at once.—*Pharm. Zeit.*, 1881, No. 13.

Bismuth in Soft Solders.—The fusibility of soft solders is increased by adding bismuth to the composition. An alloy of lead four parts, tin four parts, and bismuth one part is easily melted; but this alloy may itself be soldered with an alloy of lead two parts, bismuth two parts, and tin one part. By adding mercury a still more fusible solder can be made, but the strength of the solder is greatly lessened. Equal parts of lead, bismuth, and mercury, with two parts of tin, will make a composition which melts at 122° F., or an alloy of tin five parts, lead three parts, and bismuth three parts will melt in boiling water. In mixing these solders, melt the least fusible metal first in an iron ladle, then add the others in accordance with their infusibility. To cast strips of solder, pour a thin stream of the molten metal on a flat surface of stone or metal.

Notes and Queries.

In continuing this department, which has been found of so much value, we would remind our readers who wish for information on any of the arts and sciences, that they are cordially invited to make their wants known through this column, and those of them who can furnish accurate answers to questions asked are requested to send in replies. Doubtless many of our subscribers may know of methods, processes, or devices that may be better or more suitable for the particular case in question than anything generally known, and it is this reason that induces us to keep this department open for a medium, where an interchange of ideas and practices may be made to the advantage of all our readers. Correspondents will please send their full address when forwarding their communications—either questions or answers—not for publication, unless expressly so stated, but so that we may know where to find the writer if desirable. Communications should be sent in on or before the first of each month previous to publication, to insure insertion in next issue.

Answers.

In answer to R. G. (1).—Cathay is China; and as China is not looked upon as a particularly progressive country, the poet means to intimate that mere existence in Cathay during a whole "Cycle," or 25,000 years, would not be as full of real *life* and incident as fifty years in America or Europe. (2). The "Swiss Family Robinson," is an abridged translation of a German tale by Humbolt's tutor, Joachim Heinrich Kampe.—S. K.

12. S, N. will find that the drying and curing of skins is not a pleasant process, but many small kinds may be made useful should their owners know what to do with them, and will undertake the trouble. If the skin has already been dried, soak it in clean, and if possible, running water for twenty-four hours, working it with the hands repeatedly during the time, until it becomes quite soft. If the skin is soft and fresh, it will only need washing to remove the dust and dirt, and careful scraping to remove any particles which may have adhered to the skin. Allow the soaked skin to drain until most of the moisture has left it; then lay it on a firm table with the hair underneath. Prepare the following mixture, and apply as directed: Alum, 5 lbs.; salt, 2 lbs.; coarse wheat, oats, or corn meal, 2 lbs. Powder all the ingredients carefully, and mix gradually in a stoneware jar, or wooden bucket, with enough sour milk or sour buttermilk to bring it to the consistency of cream. Then, taking some of it, rub it thoroughly into every part of the fleshy side of the skin, using as much force as possible to drive the mixture into the pores. Give the skin as much rubbing as possible. Repeat this process daily for eight or ten days, laying the skin away each night, with plenty of the mixture to cover it, and folding it together with the fur side outwards. When it appears sufficiently tanned, wash as at first, in clean water, repeating the washing until there be no salt left in the skin, because, if any be left, the skin will grow damp on every moist day. The last process is to apply a strong solution of alum without salt, and lay the skin to dry, exposed to the sun, if possible. When dry it will be as hard as a board. Now roll it up into a tight roll, with the fur outside. Take a wooden mallet and beat it till it becomes less stiff. Open it out and stretch it as follows:—Get any blunt instrument with a rounded edge—a large shoemaker's rasp, for instance—and, laying the skin on the floor, proceed to work it from the centre to the sides with the blunt end of the tool, steadying the skin by placing the foot upon it, using the tool with the right hand and holding the skin with the left. When thoroughly worked all over, smooth with pumice-stone, and it is finished. The foregoing recipe is an excellent one, and easy to follow. I have seen handsome rabbit-skin rugs, made of skins cured by this process by the younger

brothers and sisters of a large family, and in one instance I saw a lady's cloak with a fur lining, the skins of which had been prepared by the brother of the lady to whom the cloak belonged.—AMATEUR.

13. To "Victor."—In making choice of woods for inlaying, several things have to be taken into consideration, namely: the purpose for which the work is intended, the limit of expense decided upon, and the character of the work itself. To the first of these considerations it may be said that if the inlayed work is intended for a cabinet, work-box, jewel case, stand-top, or similar work, then the woods should harmonize in color and texture with the main body of the work. For instance, if a cabinet be made of mahogany, then the inlay in the door, drawers or side panels may be of teak, rosewood, or even lignum vitæ. Sometimes ebony is used for inlaying mahogany, but this, we think, is bad taste, as mahogany color is quiet and unobtrusive, and a black inlay makes too strong a contrast. To the second consideration we may say that if expense is no object, ebony and satin-wood make a very chaste combination, and look exceedingly rich, if the design is appropriate and the work done well. Do not use holly with ebony; the holly soon becomes weather stained and creamy looking if not protected by glass or other covering. Of course, for the finest of work, ivory and ebony combined, if too much of the former is not used, make a pleasing contrast, but to be effective the work must be well done. With regard to the third consideration, if the work is very fine and the design intricate, the woods must be chosen with a view to their strength of fibre as well as to their harmony of color; if, on the other hand, the design is large and simple, then the cross-grained woods will answer very well. Ash and walnut, oak and walnut, walnut and cherry, walnut and rock maple, mahogany and rock maple, or amaranth and rock maple, will make very handsome combinations when properly handled. Oak and walnut, the former being the inlay, has a very quiet and pleasing effect.—F. T. H.

14. To bleach skeletonized leaves "Nellie" should proceed as follows: Having first taken the pulp all from the leaves, take four ounces of chloride of lime, and a pint and a half of cold water, mixed. When settled, pour off the clear liquor and cork up closely in a bottle. Procure a wide-m uthed jar, and put a teaspoonful of this bleaching liquid to half a pint of water, and in this immerse the leaves until they become white. They should then be washed carefully in cold water and dried on white blotting paper, then gently pressed flat, and placed away and labeled.—S. N.

15. The following is offered to R. T., on the coloring of leaves in Autumn. It is taken from a new work on "Forest Tree Culture": "The coloring of autumnal leaves appears to be due to the formation of organic acids from the absorption of oxygen, and caused by a ripening process, similar to that which colors ripening fruits. It is not the effect of frost, as many people believe, but may be hastened by the cool nights alternating with warm days, that often occur in autumn. The autumnal coloring of European forests is sometimes bright, but never as brilliant as in our Northern States and Canada. Its prevailing colors are yellow, shading off into tints of pale orange and reddish brown, while in our Northern forests it is often the brightest scarlet and orange, a rich golden yellow, or an intense purple, but all passing gradually into a nearly uniform shade of brown."—S. N.

16. R. W., Andover, N. Y.—Send to Chas. E. Little, 59 Fulton St., New York, for his scroll-saw catalogue.

17. J. N., Philadelphia.—The following engravings show a design for a self-acting fountain: Fig. 1 shows a finished and decorated design of fountain. Fig. 2 shows a basin A, and two cisterns B and C; to start the fountain, water is poured into basin, and runs through pipe D, filling cistern C, and leaving basin half full, the tap in pipe E is then turned, shutting off the only escape for the air, leaving only the way in through

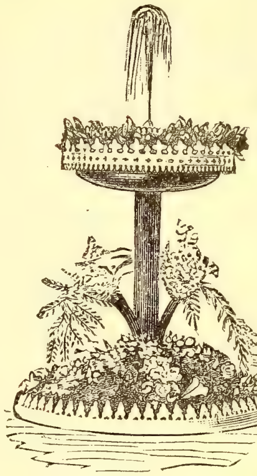

Fig. 1.

pipe D, and the way out through pipe F; now take the small bent tube H, placing one end in pipe D in basin, and blow for half a minute; this will drive the water out of cistern C, through pipe F into cistern B. While the water is passing into cistern B, the air is escaping through pipe E

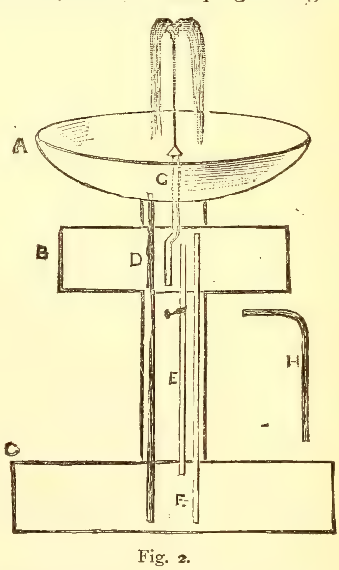

Fig. 2.

(replacing the water in C) by the tap, which acts as a vent as well as a shut off from cistern. Cistern C is now empty, and cistern B full, and the fountain ready for playing—turn the tap, the water will then pass from the basin, through pipe D into cistern C, driving the air through E, and pressing on the water in B, drives it through the

jet G. When done playing, turn off the tap, place the bent tube H into pipe, and blow as before; turn the tap and the fountain will recommence. Of course everything about this must be made tight and perfect, to insure success. The tanks and basin may be made of zinc or other similar metal.—X. Y. Z.

18.—In answer to the request of F. E. F., Lancaster, Pa., I send the enclosed designs for monograms. The combinations are simple, easily made, and are admirably adapted for scroll sawing and inlaying.—U. S. NAVY.

19. S. O. G.—Æsthetic is a word of many meanings at present. In the end we think it will mean a great improvement in all our surroundings in daily life, and a greater knowledge of what is beautiful and true in ourselves, our houses, and our dress. The dictionary says, "Æsthetics: perception of the beautiful."—SUSIE.

Queries.

20. BIG BOY, Utica, N. Y.—Thanks for your answer to my query, No. 8, about wood-carving, given in last month's YOUNG SCIENTIST. I shall make use of the information to the advantage, I hope, of myself and brothers. May I apply again for information, and ask of you, or some of your readers who may be able, to give the etymology of the word "derrick?"

NOTE.—Derrick, according to Webster, was originally an abbreviation of Theodoric, which in old Saxon was made *Detrich*, and in German *Dietrich*. Derrick, as now used, means simply a temporary crane, and is mostly used by builders and quarrymen. It was so called from Derrick, a celebrated Tyburn hangman, who lived early in the Seventeenth Century, during Queen Elizabeth's reign, and who beheaded the Earl of Essex in 1601. The term used to be an equivalent of "gallows."

21. MATILDA, Newark, N. J.—I desire to know what flowers and trees were dedicated to the heathen gods by the ancients, and also, if trees flowers or shrubs were ever dedicated to any of the saints in the Christian church. Any information on this subject will be duly appreciated.

22. TOM H., Providence, R. I.—Will some reader explain what is meant by a "divining rod," its uses, etc.?

23. MONOGRAMS.—J. H. P., Brooklyn, N. Y.; T. W. T., Philadelphia, Pa.; and S. N. B., New Britain, Conn., desire monograms of the letters sent. Will some of our clever readers send us in for reproduction combinations of the above letters. Use good black ink on smooth white paper.

24. NINA, Toledo, O.—There is a method of transfering colored prints to glass, and giving them a semi-transparent appearance. Will some reader of the YOUNG SCIENTIST inform me how the work is performed, and oblige?

25. TRANSIT OF VENUS.—ROBERT H., Boston, Mass.—Will the Editor of the YOUNG SCIENTIST, or some competent reader inform me why so much "fuss" was made about the "Transit of Venus," its significance, and how the results are obtained?

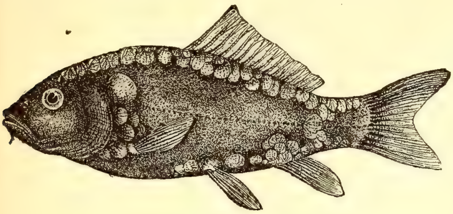
NOTE.—We take pleasure in referring Robert H. to an article on another page by Prof. Berlin H. Wright, whose skill in making abstruse astronomical problems clear to the most common minds is well known. This article on the Transit of Venus covers, we think, the whole ground embraced in the questions asked. A careful reading of the paper cannot but result in conveying valuable information to the uninitiated in matters of astronomy.

Market Report.

The German Carp.

Foremost amongst the novelties offered to our young friends this season is the German carp. This now famous fish was originally found in the large rivers of Germany, where many years ago, by careful cultivation, selection and breeding, it was greatly improved in flavor, size and habit. Several new and greatly improved breeds have also been produced. The varieties best known in this country are the scale carp, leather carp, and mirror or king carp, which is the most highly prized of all varieties of carp, either native or foreign, its flavor, when bred under proper conditions, ranking very high amongst fresh-water fishes. The German carp has been introduced as a table fish throughout Europe, Asia and Australia, and since the spring of 1877 up to the present time, large numbers have been distributed to all parts of the United States by the U. S. Fish Commissioners at Washington. The first importations of the German carp were brought over from Germany by the German fish culturist, Her von Hessells, and were planted in the U. S. Commissioners breeding ponds at Washington, whence, as they increased in numbers, they were distributed to the fish commissioners of each State, who again distributed them to all persons having suitable ponds, either natural or artificial, wherein to breed them; not for ornamentation or for the aquarium, but for the purpose of increasing the food supply of edible fish and reducing the cost of this article. All the varieties of the German carp are remarkably tenacious of life, and will undergo sudden and severe changes of temperature, as a rule, without injury. In moist and cool weather the leather and looking-glass carp can be transported alive long distances in what is known, among fish culturists, as "dry packing," which consists of a packing of damp moss. The food of the carp is entirely of a vegetable nature, and, curious to relate, the leaves of tender and crisp lettuce is a favorite diet with our foreign fish friend, also bread, boiled potato parings, rice, and the green scum that forms and floats on the surfaces of standing ponds, or grows on the stems and leaves of aquatic plants; all these he devours with much gusto. In fact, all vegetable refuse is acceptable to this very interesting fish. From the first importation of the German king carp I obtained some six small specimens no larger than the one shown in the

illustration. These, after being well fed every day for a period of two years and a half, attained the size of six inches, and had they been in a pond, instead of a comparatively small aquarium, the increase would have been still greater. In course of time they become so tame that they



GERMAN CARP.

would feed from my hand. It is best to obtain a few of them when very small, and bring them up the first year in an aquarium; in this way you can break them in so that when set free in the pond they will, by their example, teach the wild carp to feed from your hand without fear.

I can not imagine a more profitable and pleasant investment of a small amount of capital and time, for young men whose parents are owners of or are interested in fresh-water lakes or ponds, than to address a letter to Professor S. F. Baird, U. S. Fish Commissioner, Washington, D. C., giving a description of the body of water over which they have control, and the proper number of carp needed for stocking said pond. In this way you can obtain all information required to obtain the carp free of all charge, except the can for transportation and cost of transportation. The accompanying illustration of the mirror or king carp was taken from a living specimen kindly furnished by Fish Commissioner of New York State, Eugene Blackford, who is now distributing young carp bred in the government breeding ponds at Washington.

The Golden Ide.

A very beautiful and graceful fish, closely resembling in form and size our fresh-water roach, has lately been imported from England. This fish is of a uniform delicate reddish-orange color, similar to that of the gold fish, but more delicate. These beautiful strangers are to be sent to the Washington breeding ponds, and also to the experimental ponds at Cold Spring Harbor, Long Island. It is thought that they will never attain a size greater than from four to six inches, and should this be the case, the gain will be great for our young scientists, as they will have a far more beautiful fish for their fresh-water aquaria than even the pretty gold-fish.

Retail Prices.

IMPORTED CAGE BIRDS.

Canaries, *Belgian*, per pair	$6.00 to 15.00
" *French*, each	8.00 to 15.00
" *German, Hartz Mts.*, each	2.50 to 10.00
Gold Finches, each	1.50
Gold Finch (mules), each	2.50 to 5.00
Bull Finches, each	$2.50
Bull Finches (tuned), each	10.00 to 40.00
African Finches, per pair	2.50 to 5.00
Chaf Finches, each	1.50
Linnets, each	1.50 to 2.00
Linnets (mules), each	1.50 to 2.00
Green Linnets, each	1.50
Java Sparrow (blue), each	1.50
Java Sparrows (white), each	4.00 to 6.00
English Sparrows, per pair	1.00
Siskins, each	1.00
Gray Cardinal, each	4.00 to 5.00
Nightingales, each	8.00 to 25.00
Japanese Nightingales, each	5.00 to 10.00
Thrushes, each	5.00
Skylarks, each	5.00
Troopials, each	7.00 to 12.00
European blackbirds, each	5 00
Black-caps, each	4.00
Starlings, each	4.00 to 6.00
Ring Doves, each	2.50 to 3.00

AMERICAN CAGE BIRDS.

Canaries, each	2.50
Mocking Birds, females, each	1.00
" " singers	12.00
Robins	2.50 to 5.00
Blue Birds ("Blue Robins") each	1.50 to 2.00
Indigo Birds, each	1.00
Nonpariel, each	1.50 to 2.00
Virginia Cardinal, each	3.00
Bobolinks, each	1.50 to 2.00
Yellow Birds, each	1.50 to 2.00

QUADRUPEDS.

Terriers, *black and tan*, each	5.00 to 30 00
Terriers, *Scotch and Skye*, each	5.00 to 30.00
Newfoundland Pups, each	10.00 to 15.00
Pomeranian or Spitz "	5.00 to 15.00
Greyhounds, *English*, "	10.00 to 25.00
Greyounds, *Italian*, "	10.00 to 30.00
Guinea-Pigs, *common*, per pair	1.50
" " " large	1.50 to 3.00
Guinea-Pigs, *all white*, "	2.00 to 4.00
Squirrels, *gray*, "	5.00
Squirrels, *all white* "	15.00 to 25.00
Squirrels, *flying* "	3.00 to 4.00
Squirrels, *small red* "	2.00
Rabbits, *common*, per pair	1.00 to 2.50
Rabbits, *fancy breed*, according to age and purity of breed, per pair	3.00 to 15.00
Ferrets, *English*, "	15.00
Raccoons, each	4.00 to 5.00
Cats, *Maltese* (males), each	5.00
" " (females), each	3.00
Cats, *Albinos, pink or blue eyes*, each	3.00 to 5.00
Rats, *white China, pink eyes*, per pair	1.50
Rats, *piebald*, per pair	1.50
Mice, *white, pink eyes*, per pair	0.50
Mice, *piebald*, per pair	0.50
Fine Shells for Fancy Work, according to colors and variety, per quart	1.00 and up.

Prices Paid for Pet Stock by Dealers.

At this season of the year the prices paid for pet stock of all kinds are very low; this is on account of the demand for said stock falling off greatly after the holidays. Rabbits (common) are now ranging from 50 to 75 cents per pair, according to age and color.

Guinea-Pigs, per pair	$0.40 to 0 75
Squirrels, *gray*, each	0.50 to 1.00
Squirrels, *flying*, per pair	0.25 to 0.50
White mice, per pair	0.15 to 0.20
Aquarium fish *(now scarce)* per hundred	1.50 to 2.00
Gold Fish *(now scarce)* per hundred	8.00 to 10.00
Aquarium Plants *(now scarce)* per hundred bunches	5.00
Small Marine Shells for Aquaria, per quart	0.50

For all information on this subject, as to reliable dealers, etc., etc., send postal card to YOUNG SCIENTIST,

EXCHANGES.

Only those who are *yearly* subscribers, and whose names are entered on our books have the privilege of inserting exchanges.

Exchanges must be on separate slips of paper or postal cards. If mixed with business matter in letters or cards they are filed away and never reach the printer.

Exchanges must not exceed thirty words.

Buying and selling belong to the advertising department.

We reserve the right to omit the exchange column, when we have not room for it, and the amount of space at our disposal will regulate the number of insertions given to each *exchange*, the preference being always given to those who have not previously used our columns.

Bee Hive wanted; one of the old-fashioned straw "skeps"; say what you would like in exchange. Apis, care of Young Scientist, 49 Maiden Lane, N. Y.

A first-class type writer, in excellent condition, cost $125.00, to exchange for good microscope, telescope, or valuable scientific books; send full particulars. A. B., Box 114, Lewiston, Maine.

A $30 stencil outfit (Spencer's) for a self-inking printing press in good condition, chase about 6 x 9; rich ores and minerals of Idaho for scientific and instructive books, printing press, type, etc. J. P. Clough, Junction, Lemhi Co., Idaho.

Wanted pyrites of iron from Colorado gold mines in exchange for sea shells and other gems; send list of what you have to exchange. S. Ferguson, Eureka Springs, Arkansas.

Scientific specimens of various kinds for same. Geo. E. Frazier, Caldwell, Ohio.

A banjo in good condition, two pairs of rosewood bones, three splendid games, and a fine set of drawing instruments, for a good cornet, viola, violincello or double bass. L. B. Hill, Kalamazoo, Mich.

A good telescope, also foot-lathe and saw combined, each worth $10.00, for shells, fossils or relics. Independent, Conncautville, Crawford Co., Pa.

Birds' eggs to exchange for others; send list of what you have to exchange. Emil Laurent, 621 Marshall St., Philadelphia, Pa.

Lester W. Mann, Randolph, Mass., Box 162, has Demas scroll saw, lathe and tools, emery wheel; $20 worth patterns; Smithograph; large harmonica, cost $1.75; novelties in seeds; for large self-inking press or offers.

10 volumes Chambers' Encyclopædia, American Book Exchange edition (cloth); Bonanza printing press, chase 3 x 5, card type, ink roller; spyglass, power 10 times; for French triplet, 1-5 in., or offers. H. P. Nichols, P. O. Address, Bridgeport, Conn.

Twelve or fifteen volumes of the American Agriculturist to exchange for scientific books or offers. W. H. Osborne, Chardon, Ohio.

J. D. Rice, P. O. Box 473, Trenton, N. J., would be pleased to correspond with mineralogists for the purpose of exchanging specimens and ideas.

To exchange, my collection of nearly half a thousand rare postage stamps with catalogue, for second-hand Flobert rifle; must be in good condition. H. E. Whitman, Station M, New York.

I have a large assortment of foreign stamps to exchange, also Confederate money. Collectors send sheet and I will return it with mine. Box No. 2, Coeymans, N. Y.

Electric bell engine, cost $15; pair of analytical scales, cost $10; pair of Bell Telephones to exchange for a printing press, watch or offers. Geo. N. Bigelow, Box 754, Palmyra, N. Y.

Any person wishing to trade bird's eggs may apply to me and I will send them my list of bird's eggs. I have only a few at present, but am receiving a number every month. A. G. G., Box 26, Summit, New Jersey.

Minerals of Idaho for Standard Works on the Horse—Wallace's Registers and turf journals. Wanted, also other useful books, bound and in good condition. Many varieties named in my list. J. P. Clough, Junction Lemhi Co., Idaho.

To exchange for offers first four (fifth when completed) bound volumes of YOUNG SCIENTIST. J. N. Brooks, P.O. 1468, N. Y. City.

Wanted engraver's tools with book of instructions, for a Victor Press, with cabinet, 2 type cases, type, ink roller and furniture complete; perfectly new. L. Warren, 72 Cumberland St., Brooklyn, N. Y.

A Fletcher Foot-Blower, cost $5, as good as new; will exchange for a Cushman, 2 in. or up scroll chuck, or other make; will give a satisfactory trade on the difference in price, if any. Louis Lutz, St. Clair Street, Toledo, O.

I have a lot of "Galaxy" (magazines) which I would like to exchange for an air rifle in good condition, a collection of birds' eggs, or offers. W. B. Greenleaf, 480 La Salle Ave., Chicago, Ill.

I have a Mechanical Telegraph with book of instructions, books, etc., which I wish to exchange for good microscopical objects, mounted on 3 x 1 slips. Address, with list, J. H. Frey, Millersburg, Ohio.

To exchange, "How to Use Microscope," Wells' "Natural Philosophy," and many other books, chemical apparatus, etc., for good photographic camera, and lenses. W. H. Weed, 254 Putnam Ave., Brooklyn, N. Y.

Wanted "Quimby's New Bee Keeping," for "Our Own Birds of the United States," by W. S. Baily; new. Joseph Anthony, Jr., Colota, Whiteside Co., Ill.

Wanted a good book in anatomy, in exchange for a book on chemistry, or for story books. A. G. G., Box 26, Summit, New Jersey.

A German-silver trimmed, patent lined, cocoa flute, cost $4, in good order, for good spy-glass, photo-material, or offers. Ewing McLean, Greencastle, Ind.

I have some fossil shells from the west bank of the Mississippi, to exchange for Indian relics. A. W. S., 187 E. 71st St., N. Y.

I have a magic lantern, Ruby pattern, nearly new, and 5 views; also "Our First Century," bound in leather, cost $7; state what is wanted in exchange. I. N. Spencer, Box. 217, So. Manchester, Conn.

First-class telegraph instrument and attachments, and "Wood's Botany," for bound volumes of periodicals, books, or offers. H. P. Albert, Anderson, Iowa.

Wanted a book on treatment and care of canary, also breeding of same; will give in exchange book named "Market Garden, Flower Garden and Bees," or 40 "Scientific Americans" or "Seaside Libraries;" want also old books. M. J. Mulvihill, Norwalk, Conn.

Coins, minerals, stamps, books, type, fishing tackle (very complete) and fish pole, bronze inkstand, etc., for coins, medals, stamps, war envelopes, old newspapers, and Continental, Colonial and Confederate currency. F. F. Fletcher, 103 Main St., St. Johnsburg, Vt.

Blow-pipe set (cost $10), large illustrated family Bible (cost $7.50), for Wood's Botany, Dana's Geology, or printing press and type. H. W. Noble, Box 134, South Dansville, N. Y.

Wanted, offers for fossil shells from the west coast of Africa. A. W. Seward, 187 E. 71st St.

I have a number of birds' eggs I should like to trade for other birds' eggs; send for list of trading eggs. A. G. G., Box 26, Summit, New Jersey.

For a microscope stand or offers, a 36-inch turning lathe (new) and a number of scientific books; send for list. A. Kendall, Somerville, Mass.

Wanted services of amateur printer with small office (or large), in exchange for an interest in a well-established weekly paper, good size. Eagle Office, Plymouth, N. H.

American Agriculturist microscope, new, cost $15, for amateur photographic apparatus, lever watch, 22 calibre breech-loading sporting rifle or magic lantern of equal value. Wm. A. Walker, Rockland, R. I.

I. T. Bell, Franklin, Pa., has back numbers of Scientific American, Forest and Stream, and Young Scientist, good flute, chessmen, books, etc., for good magic lantern, revolver, scarce coins, or offers.

For self-inking printing press and type, one Henry rifle, 16 shot, 44 cal., cost $40, in good order, or one double barrel shot gun, barrels London fine twist, or offers. J. B. Garrison, Belton, Bell Co., Texas.

The Young Scientist

SCIENCE IS KNOWLEDGE. — KNOWLEDGE IS POWER.

INDUSTRIAL PUBLICATI

A PRACTICAL JOURNAL OF

HOME ARTS.

VOL. VI. NEW YORK, MARCH, 1883. No. 3.

Amateur Wood Carving.

BY LEO PARSLEY.

IT is not necessary that the amateur carver should have a thorough knowledge of the various styles of decorative art, still it is desirable that he should have a fair idea of the distinctive features of each style. While it is not the intention of the writer to fully explain each characteristic of every style, it is thought necessary to describe briefly the main features of some of the historic styles of ornament.

Ornamental styles may be broadly divided into two great classes—the *symbolic* and the *æsthetic;* the elements of style are also of two kinds, the pure and absolute, and the conventional and arbitrary; or natural and fanciful. There are also two provinces of ornament—the *flat* and the *round;* in the former we have a contrast of light and dark, in the latter a contrast of light and shade. It is with the latter that we have most to deal with in wood carving, and the amateur should always bear in mind that the two great principles he has to study most particularly are shape and contrast.

In most cases where imitations from nature, such as flowers or fruit, are introduced into a design, they should be used as accessory decorations, and not as principals, otherwise there is a risk of substituting the ornament itself for the object to be ornamented, and in every case ornament is essentially the accessory to, and not the substitute of, the useful. As the motive of ornament is to render the object ornamented agreeable to the eye, the details of the decoration should be kept purely subservient to the beauty of effect. Let me here caution the amateur never to overload his design with a multiplicity of details, as by so doing he increases the labor of production, and at the same time spoils the effect of the design as a whole.

Symmetry is such an important element in decoration that it must never be

disregarded. In art, as in nature, it is the *group* that is the ornament, and not the individual; and this law must be observed by the designer. In clusters, festoons, etc., of fruit or flowers, the individuals may be arranged at random, but the cluster or festoon itself must be of symmetrical proportion.

This law of symmetry is so important that it has been stated that there is no form, or combination of forms, whatever, that when symmetrically contrasted and repeated, cannot be made subservient to beauty—in fact, the whole grammar of ornament consists simply of contrast, repetition and series. I would again impress upon the amateur designer the necessity of scrupulously avoiding an overloading of detail; he should first of all consider utility, making detail merely a secondary consideration, endeavoring at the same time to so group the details or to provide against injury by the skilful adjustment of the relieved portions to the situation, or use of the decorated object.

Taste in design, I need hardly say, is of paramount importance; and no amount of mere mechanical skill can counterbalance the effect of a badly conceived design. Strange as it may at first sight appear, it is nevertheless true, that in no popular style of ornament have purely natural details ever yet prevailed. It is true that in all the great styles, the details are largely derived from nature, but for the most part conventionally treated. A plant or natural object is said to be conventionally treated when the natural order of its growth or development has been disregarded. The distinction between the natural and conventional, or ornamental treatment of an object, should be clearly understood. In Fig. 1 the engraving represents an ivy leaf conventionally treated, and it will be seen, that though the scroll is composed of strictly natural parts, still as no plant could grow in an exact spiral direction, the scroll form constitutes the conventional arrangement.

Every design is composed of two parts—plan and details; as in a bracket, the shape of the bracket is the plan, the decorations of the bracket are the details of the design, and these details may either cover the entire surface of the bracket, or only portions of it. Decorations which

Fig. 1.

uniformly cover the entire surface of an object are usually called diapers, and are commonly composed of a series of the same ornament in a vertical, horizontal, or diagonal order. Diapers, as in Fig. 2,

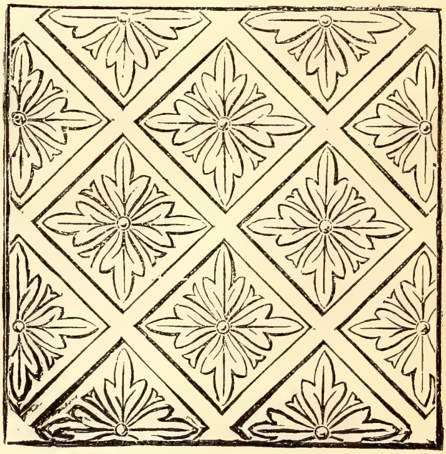


Fig. 2.

are best suited for flat surfaces, and have the best effect when arranged diagonally. The majority of the ancient mosaics are diapers of a geometrical pattern. It appears that the first principle of ornament is repetition; take a moulding, for instance, where we have simply a measured succesion in series of some one detail.

The nine great styles into which ornament may be broadly divided may again be subdivided into ancient, mediæval and

modern. The three ancient styles are the Egyptian, the Greek, and the Roman. The mediæval styles comprise the Byzantine, Saracenic, and the Gothic; and the modern styles are the Renaissance, the Cinquecento, the Louis Quatorze, and the Queen Anne. Style is simply another name for character, and frequently is merely a modification or peculiar elaboration of the details of a previous style. To commence with the Egyptian, we find that many of its forms of ornament are still popular—as the fret, wave-scroll, spiral, and zigzag; but the most symbolic features of this style are the winged globe, the lotus and papyrus, and the asp. Many of the forms, and indeed the very details of the Greek style, are still popular, as they so well represent the great principles of ornament, series, and contrast—contrast of masses and contrast of lines. Some of the principal characteristics of this style are the well-known

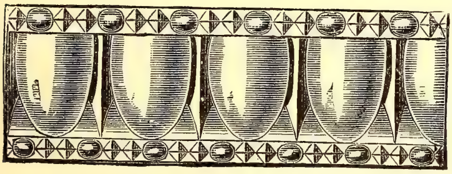

Fig. 3.

espinos, or egg and tongue, as Fig. 3, the astragal, and the scrolls.

In the egg and tongue we get a bold contrast of light and shade, and we have a similar result, though not so marked, in the astragal. It is now, too, that we arrive at carved, instead of painted, ornaments as in the Doric period.

The Roman style is simply an enlargement or enrichment of the florid Greek—

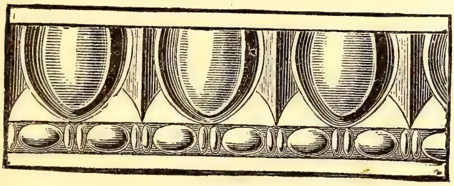

Fig. 4.

in fact, the chief characteristic of this style is its uniform magnificence. As an example of this even in details compare the egg and tongue of this period, Fig. 4, with Fig. 3. The scroll and acanthus are also peculiarly Roman, and continually occur in the ornament of this period—in fact, every form which will admit of it is habitually enriched with an acanthus clothing or foliations. The same may be said of the scroll, which, in the elaborate development with acanthus foliations, is characteristically Roman. The introduction of grotesque forms, like that shown at Fig. 5, belongs to this period.

Fig. 5.

We now come to the middle age styles, in which we find symbols play an important part. Byzantine decorations are in nearly every case composed of ingeniously designed symbolic forms.

In Byzantine art, too, it will be found that all imitations of natural forms, and even animals and the human figure, are conventionally treated. In the decorations of this period it may be noticed that the trefoil and quatrefoil become very frequent, the former being a symbolic representation of the Trinity, and the latter of the Four Evangelists. These symbols are also common in Gothic art. The principles of the next style—the Saracenic—are soon stated. In the designs of this period we find vegetable and animal forms rigidly excluded, and curves, angles, and inter-lacings go to form the major part of the designs, inscriptions

being frequently introduced. This was the period of gorgeous and elaborate diaper decorations, the habit of ornamenting the entire surfaces of their apartments affording a wide field for the display of this branch of art. The third Middle Age style was the Gothic, and this style, perhaps more than all others, should be of interest to the wood-carver.

There is hardly a cathedral where boldly-executed Gothic carvings do not meet the eye. The symbolic elements of both the Byzantine and Saracenic styles are continued in the Gothic, but are chiefly distinguished from these styles by the universal absence of the dome. In Gothic ornament the geometrical and pointed elements are elaborated as much as possible, these elements being also frequently combined with conventional treatment of animal and vegetable forms. This is one of the great features of this style, the tracery in particular being so paramount that some of the varieties of Gothic are almost entirely distinguished by this feature. We have in this style an extensive application of foliage; and the trefoil, or as it is frequently called the Early English leaf, plays an important part, and is a characteristic feature of the ornament. Gothic ornaments, independent of tracery, are nearly exclusively leaves, fruit, or flowers—classical ornaments being excluded; and there is generally a want of finish about the details.

We now come to the Modern styles, commencing with the Renaissance, the principal features of which are intricate tracery and delicate scroll work of conventional foliage. The mixture of various elements is also one of the essentials of this style, men and animals, natural and grotesque, conventional and natural foliage, tracery and scrolls—all forming part of this mixture. The Renaissance in fact is rather a combination of various styles than a revival of any particular style.

Cinquecento is the next style, and this, as a development of art, is the most perfect of the modern styles. The Arabesque scroll work, with its graceful, pleasing curves, is a prominent feature of this style, and with this it combines unlimited choice of natural and conventional imitations from both the animal and vegetable kingdoms, either arbitrarily disposed or combined. All the efforts of this, the culminating style in ornamental art, are made to attain the most attractive results and to gratify the eye. The Louis Quatorze style shows great contrasts of shade and light, and to obtain this result exact symmetry in the parts were no longer essential; consequently, in some examples of this period we find symmetry avoided both in the balance of the whole and in the details of the parts. The individuality of this style is in the constant and peculiar combination of the scroll and shell, the other elements of the style being classical. We find also that the broad acanthus foliations have become more elongated, and that flat surfaces are not admitted into any of the designs of this period—in fact, as sudden and varied contrasts of light and shade are so essential to this style, all the ornamental details are either concave or convex.

The Queen Anne style (so called) is simply a mixing of styles, and possesses no marked distinctive features. Intaglio, sunken or incised work, is the chief characteristic of this style.

The amateur reader will glean from the foregoing some idea of the leading features of each style, and will doubtless be able to distinguish one from the other. In future numbers simple and easy designs, with instructions, will be given, so that they may be executed.

A Wrinkle for Amateurs.

THE difficulty of holding a picture-frame or other mitred work while the corners are being fastened, or the glue setting, has often been the cause of annoyance and irritation to young amateurs. Like most matters of this kind, the trouble ensued more from a lack of knowledge on the part of the workman than from actual difficulties besetting the work. The accompanying engravings exhibit a method by which picture-frames, work-boxes, small writing-desks, glove, collar, or cuff boxes may be held solid until the corners

are fastened—or, if glued—until the glue has set hard. Let *s s s s* be the frame or box; place it on a level surface, such as the top of a work-bench, table, or floor. If the joints, *o o o o*, are to be glued, the stuff must be warmed before the glue is

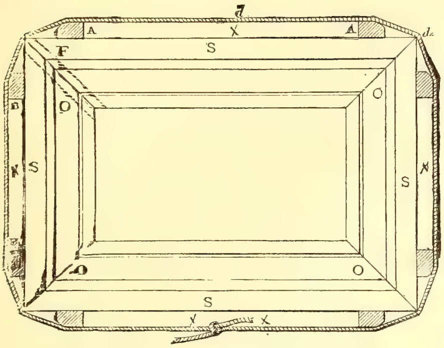

Fig. 1.

applied. Take a strong cord, *d d;* wind it round the frame, as shown, two or three times; prepare eight blocks of wood similar to those shown at A A, B B. If the work is a picture-frame, the blocks need not be longer than the frame is thick, but for a box or other work the blocks may be left any reasonable length. Of course, the cord and blocks must be prepared and tried before the glue is applied, and if any adjustment is required, it must be made at this stage; for when the tightening is once done after the corners are glued the work must not be meddled with until the glue is perfectly hard. Having got everything in readiness, apply the glue, just as hot as possible; slip on the cord as shown; then put in the blocks at *x x x x x*, and slide them along toward the corners, taking care not to slide any one of them too far at first. When the cord begins to tighten, go round the frame again, forcing the blocks nearer to the corners, and repeat the operation until the cord is stretched tight and the joints are closed up. If screws or nails are to be used in the corners, the work must be left until dry before they are driven in; and the driving should be done before the cord is loosened.

Fig. 2 shows the edge of a piece of work, with the cord and blocks, A B, in position. Sometimes the work may be from five to ten or twelve inches deep, and when this is the case, it is better to use two cords—one near the top edge and the other near the lower edge of the box—and

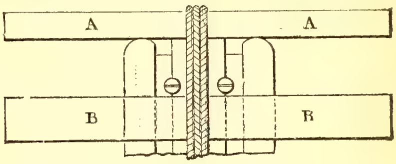

Fig. 2.

have the blocks long enough to pass under both cords; this will insure a pressure at all points on the joint, and will tend to prevent warping and twisting.

The dotted lines shown at F, Fig. 1, represent what joiners and cabinet-makers call a "feather." It is simply a strip of wood the thickness of the saw-kerf, made in the frame, where the "feather" is to go. Care must be used, when running the saw in the wood, to get the kerfs or saw-cuts directly opposite each other. The "feather' must be made with the fibres of the grain running across it. When put in properly and glued, the feather makes a strong, firm joint. Sometimes strips of metal are used for this purpose, but for fine work wood is preferable. This method need only be adopted when strength is a necessity in the joint.

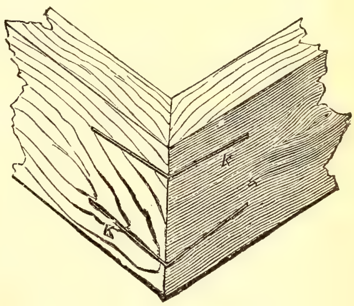

Fig. 3.

At Fig. 3 we show one corner of a box with saw-kerfs in at K K. Strips or feathers are glued in these kerfs, which help materially to hold the corner joint together. It will be noticed that these

kerfs are parallel with the edges of the box; this is the neatest way to put in the strips, and is as strong as any other when the work is neatly done, but sometimes workmen run in the kerfs on an angle, which, to say the least of it, is reprehensible, as the work, when varnished or polished, does not look so well, and is certainly not any stronger than when the strips are put in parallel with the edges.

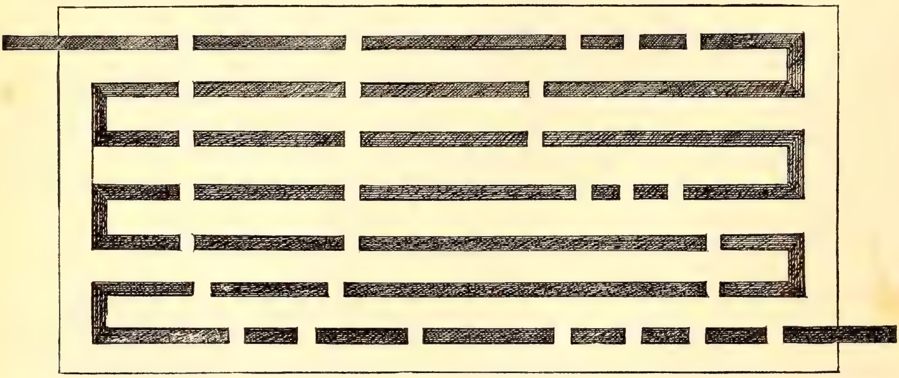
Easy Experiments in Electricity.

WHEN I first took an interest in the study of Natural Philosophy, I wanted to try some experiments illustrating the different phenomena of electricity, but I could find no simple directions for performing them without considerable expense. The object of these articles is to help others in like circumstances to get the same enjoyment and instruction, and save their money for other purposes.

On page 2, Vol. V, of the YOUNG SCIENTIST, are directions for obtaining a spark from a piece of brown paper and a bunch of keys, but you may get a longer spark with the following simple apparatus, which we call the "tea-tray electrophorus." This consists of an ordinary metallic tea-tray, supported by two glass goblets and a piece of brown paper, the same size as the inside of the tray, with a small strip of paper fastened to each end for handles. To obtain a spark, first heat the paper pretty hot, and rub it well with a clothes-brush; then lay it on the tray, hold your knuckle near it, and you will get a spark of negative electricity. Now lift the paper and hold your knuckle near the tray, and you will get another spark, but of positive electricity. I have obtained sparks in this way one and one half inches long, when the conditions were favorable.

To give a sensible shock we must have a condenser, either a Leyden jar or the following apparatus, which, though it costs almost nothing, is quite effective. Take two pieces of sheet tin, 8x10 inches, or larger, and set them on a glass goblet, with a piece of window-glass, a little larger than the tins, between them. Now take a piece of brown paper, warm it, and rub it, as in the electrophorus, lay it on the upper tin, and touch the latter; then raise the paper and touch the under tin, repeat the operation several times, and then, by touching the under tin with one hand and the upper tin with the other, you will receive quite a shock.

The explanation of this is, that when the paper is rubbed it is charged with negative electricity; laying it on the tin, the negative electricity in the paper attracts the positive in the tin, and the negative flows off through the hand to the ground. Then, when the paper is lifted, the positive electricity in the upper tin, being free, attracts the negative in the under tin. By touching it the positive flows off to the ground, leaving the under tin charged with negative and the upper



with positive electricity. By repeating this operation the charge is increased each time. As the paper does not lose its electricity, it may be used several times in succession, until the apparatus is fully charged.

A very pretty effect may be produced by pasting narrow strips of tinfoil on a pane of glass, as in the figure, and cutting across them so as to make the breaks in the form of letters or words. By connecting one end with the ground, and the other end with the electrophorus, by means of wires or chains, a spark will be produced at each break, thus forming the word in letters of light. To get good results from these experiments everything should be warm and dry. KENNETH HARTLEY.

A Home-Made Printing-Press.

BY ONE OF OUR "SUBS."

NEARLY two years ago I made a small printing-press from which I have had good service. The following is a description. A smaller one can be made by observing the proportions.

From the grocery-store I obtained two lemon boxes, having at each end and in the middle a thick piece of board, which were of hard, fine-grained wood. The boards I chose were well-seasoned and without knot or crack, and I planed them down smooth and true to $\frac{5}{8}$ in. thick $\times$ $8\frac{1}{2}$ long $\times$ $6\frac{5}{8}$ wide. I have two chases made of strips of this same wood. One is 6×4; the other $3\frac{1}{2}\times2\frac{1}{2}$. The strips are cut the desired length, $\frac{1}{2}$ in. deep $\times$ $\frac{1}{4}$ thick. The

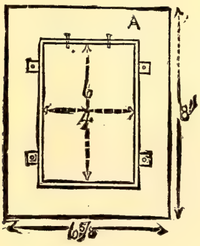


Fig. 1.

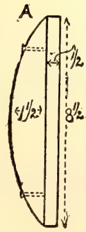

Fig. 2.

ends are dove-tailed, and, where practicable, put all around some brass to give strength. At the top insert two screws, to hold the type in place.

Now take one of the smooth boards (A), in the middle of which you screw on the chase by means of four small plates of brass, two on either side of chase, as in Fig. 1. At the back of this board (A) screw a piece of wood the same length and thickness as the board, and $1\frac{1}{2}$ in. wide at middle, as at Fig. 2.

Through the middle of this piece runs a round steel or iron pin $\frac{1}{8}$ diameter.

Make two uprights, 11 in. high, $\frac{5}{8}$ thick, $6\frac{1}{2}$ wide at base, 5 wide at top, shaped like Fig. 3. Put these uprights in a grooved board 19 in. long, $8\frac{1}{2}$ wide, 1 thick. Place uprights two inches apart (inside measurement) in the grooves, which are to be $\frac{1}{2}$ in. in depth, and so that the uprights will fit in them tightly, and screw them underneath the base board. Between the uprights, in the middle, put a piece of wood to keep them in position. This done, adjust the board (A) in such a way that the middle will rest on the top of the

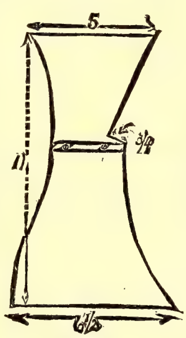

Fig. 3.

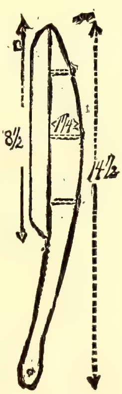

Fig. 4.

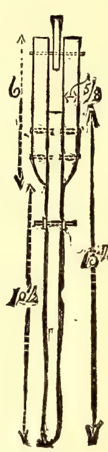

Fig. 5.

uprights, by means of the pin running through the piece of wood at the back. Hold the ends of pin in posi-

tion with staples, so that it will be as on hinges.

Now, with the other smooth board *(c)*, Fig. 4, adjust a similar piece of wood as on A, but wider in the middle, about $1\frac{3}{4}$ in. Make two pieces $14\frac{1}{2}$ long, $\frac{3}{4}$ thick, and $1\frac{1}{2}$ at widest part, Fig. 4. They are screwed

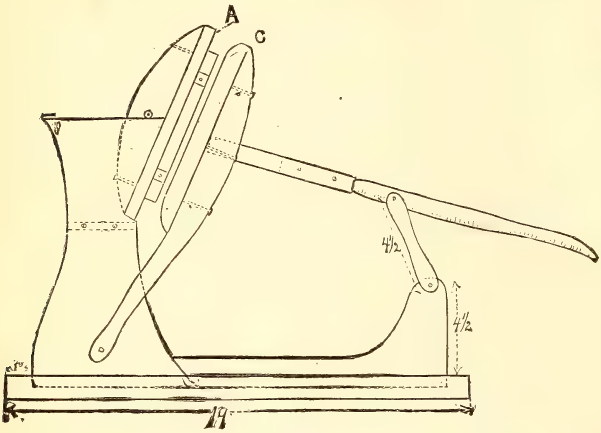

Fig. 6.

one on each side of the board, $\frac{1}{2}$ in. from edge, the top even with top of board.

Through the middle piece of board *(c)* a handle is adjusted. It is $16\frac{1}{2}$ long, $\frac{5}{8}$ thick, $1\frac{1}{2}$ wide. It fits the middle piece, and is held there by another steel pin running through handle and board.

The end of handle is held up by two pieces about $4\frac{1}{2}$ long, $\frac{5}{8}$ thick, 1 wide, one on each side of handle, and held there by a steel pin running through. Below, these pieces are held by a pin through them and through the two pieces of board which are above the base-board $4\frac{1}{2}$ in. All these joints must work easily. Fig. 6 represents a side view of press completed.

The adjustments depend not so much on the measurements as on the slope in the uprights. It is well to put the type in the chase first, and when board *c* is brought towards them, see whether they touch it equally and all over; if not, either make your slant slope more or less; and your long pieces on *c* advance more or less, as the case may be.

To put my type in the press, I turn up the chase and board (A) and insert type. To prevent this board from falling backwards, I screwed a small piece of wood across the top. On this the chase-board (A) rests, and a small hook prevents it from falling in its place.

C, Fig. 6, should be well padded with thick blotting-paper, as this makes a soft cushion for the type to press against. Paper and cards to be printed are held in various ways, pins, cord, elastic, etc. The figures are all drawn by a scale of $\frac{1}{8} = 1$ inch, and will make the explanations more clear.

Do not keep your press in too warm a place, nor wet it, as the wood may warp. Type, rollers, etc., may be had of the Young America Press Company, No. 19 Murray Street, New York City. A good surface to spread ink on can be made of a piece of sheet iron or zinc nailed to a board.

Something About Saws.—II.

BY "OUR NED."

HAND-SAWS for crosscutting require a great deal more skill to put and keep in order than the ordinary rip-saw; the latter, if intended for cutting soft wood, has all its teeth filed at right angles with the line of points, or, in other words, it is filed square across, the file being held in a horizontal or level position.

Fig. 1 shows a fair-sized rip-saw, the blade being about twenty-six inches long,

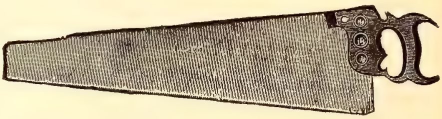

Fig. 1.

which is quite long enough for an amateur to use. A saw of this size should

have about three teeth to the inch. There should not be more than this number, but there may be less, as two and a half teeth to the inch will give very fair satisfaction, but it requires more force to drive a saw this coarse through the wood than if the teeth were finer.

The blade of a rip-saw should be a little stiffer than that of a crosscut, and should be perfectly straight, and ground thinner on the back than on the cutting edge; this will admit of the saw having less set than would otherwise be required. The shape of the teeth should be about as shown at Fig. 2. It will be noticed that the teeth are *underfiled*, or that the cutting face forms an acute angle with the line of teeth. If the cutting face of the teeth form right angles with the cutting edge the saw will not work free and with ease, as the teeth will not cut the wood, but rather pound out the sawdust. Each tooth should act on the end grain of the

Fig. 2.

wood, as a narrow chisel would; and to do this it is quite necessary that the teeth should be underfiled, or made hooked, as shown in the figure, but care must be taken not to give too much hook, for in that case the teeth would be made weaker at the base, and would be apt to break off under the operation of setting, or if the saw should run foul of a hard knot while in use, the same result might follow.

While it is necessary to warn the filer against making the teeth too much hooked, it is just as necessary to inform him that a limited amount of hook is required to give clearance to the sawdust. If the throats or gullets of the teeth are too small—which would be the case if the teeth were not filed under a little—the sawdust would fill up the spaces between the teeth, if the stuff being cut was more than a couple of inches thick, and therefore impede the progress of the saw, causing a loss of time and labor.

For amateur use the teeth shown at Fig. 2 are probably the best in shape, if for soft wood only. If, however, the saw is intended to cut hard wood, the teeth might have a trifle less hook and be filed a little beveling on the face, being careful not to file the back of the teeth beveling. Saws intended for ripping hard wood only may have more teeth to the inch than those intended for cutting soft wood. From four to five teeth to the inch will answer very well for amateur use on hard wood, though this is somewhat finer than the expert workman uses for the same purpose. The fewer the teeth in a saw within certain limits the faster it will cut, but as a matter of course will require more force to drive it through the material, and the work will not be so smoothly done as if performed with a saw having more teeth.

In using a rip-saw, the amount of work done in a given time depends somewhat on the angle at which the saw is held while in use. The position and inclination of the tool, as shown at Fig. 3, is the most convenient and at the same time the most efficient inclination for the saw to

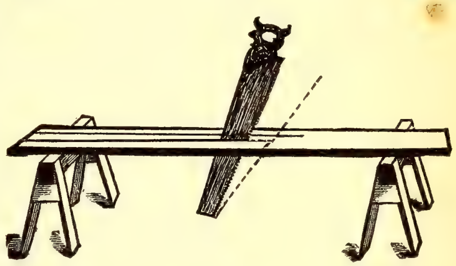

Fig. 3.

be held. If tipped over until the line of teeth is parallel with the dotted lines, it will scarcely cut at all, owing to the fact that the throats would be choked with the shavings scraped off the wood by the points of the teeth. If held perpendicular, the points of the teeth will strike the fibres square across their ends, which will make it severe on both saw and sawyer.

The clamps used for holding a crosscut saw while being filed will answer for the

rip-saw just as well. In some instances, where the amateur can afford it, it may be advisable to procure some one of the many metal saw-clamps that may be obtained for one dollar and upwards. Some of these devices are very handy, and may be attached to a bench or work-table on short notice. They are made to grip the saw-blade firmly for at least one-third the length of the blade. I would prefer, however, that the amateur make his own clamps, and use them until he becomes pretty well up in using tools, when, if he thinks fit, he may procure one of the iron clamps.

As I have before stated, a rip-saw intended for cutting hard wood should have its teeth filed a little beveling on the face edge, similar to the teeth shown in Fig. 4,

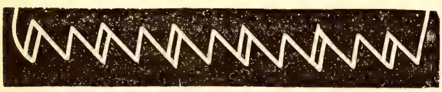

Fig. 4.

but with less bevel than there shown. There are also more teeth shown to the inch in the engraving than should be in the rip-saw.

A saw filed like that shown at Fig. 4 will rip hard wood pretty well, but it is more suitable for a saw intended for cutting soft wood in all directions, such as a bow-saw, a compass saw, or a key-hole saw, of which I will tell you more anon.

In choosing a file for sharpening a rip-saw, get one about six inches long from point to point. I always prefer a stub-pointed file for a rip-saw, and of course, I need hardly tell you that the file must be three-sided and parallel in this case. A taper three-sided file does very well for a crosscut saw, but I prefer in all cases a stub-ended file. When selecting a file, hold it to the light in a horizontal position, with the point toward you. The teeth of the file will now have their points facing you, and you can easily detect any flaw or imperfection, and if the teeth are irregular or uneven, or the color not uniform, do not take it. A file with a mottled or spotted appearance has not received an even temper. If, however, it presents a clean greyish color, even and regular, it denotes that the file is well and evenly tempered, and will no doubt give good satisfaction.

Indian Clubs, and the Way to Use Them.—II.

BY JAMES C. SQUIRES.

(Continued from page 8.)

FOR the second exercise (Fig 4), commence as before, and when both clubs are raised above the head, *reverse* the direction of the left one, and instead of describing the circle from right to left, swing it from left to right, the right club at the same time continuing its original course. A glance at Fig. 4 will show the exercise; the

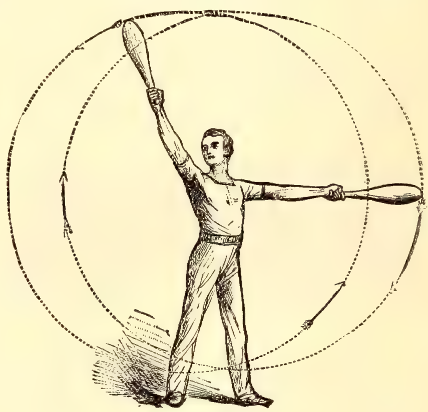

Fig. 4.

dotted lines and arrows indicate the direction in which each club travels. In this exercise (and in many others to follow) the clubs cross twice in each circle; care must therefore be taken not to allow them to come into collision (which catastrophe can be easily avoided by following the directions recently given—viz., to keep the base of each club in a straight line with each shoulder).

Exercise 3 (Fig. 5.)—This is the same as No. 2, with an additional movement—viz., that when each club is raised in its turn above the head to its highest point, the circle is checked and the club dropped behind the head, and made to describe a smaller circle in the rear of the shoulder, after completing which the larger circle

is resumed. The dotted line in the illustration shows the course of the *left* club

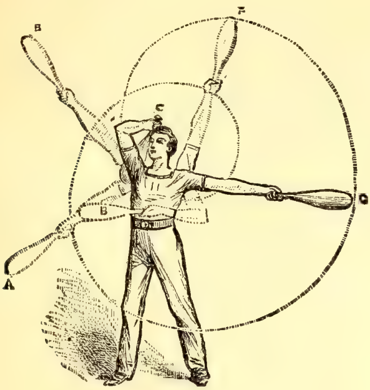

Fig. 5.

only, but the right club does the same thing in the opposite direction.

Exercise 4 (Fig. 6).—Commence with Exercise 1, and when the clubs are raised above the head allow them to drop and

Fig. 6.

make them describe a small circle behind the shoulders, then resume the larger circle on front of the body.

Exercise 5 (Fig. 7).—This is the first of the wrist "twists," and is a movement that will tax the power of the forearm rather severely. Start from the position shown in Fig. 2, and describe a circle with each club *from the wrist* in the direction shown by the dotted lines and arrows. In practicing this exercise, you will experience a tendency to drop the arms with the clubs, but you must endeavor to keep them in the position shown, *making each wrist the centre of each circle.*

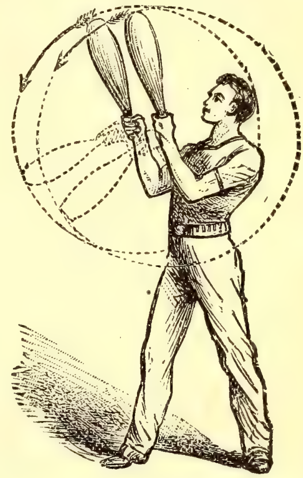

Fig. 7.

Exercise 6 (Fig. 8).—Now for a twist in which each club describes a circle in an opposite direction. Again be careful to

Fig. 8.

avoid a collision, and keep the wrists level and opposite each other.

Exercise 7 (Fig. 9).—This is rather difficult, but with a little perseverance you

will be able to accomplish the movement, and as it is very pretty it is well worth

Fig. 9.

the trouble. Carefully study the illustration, and follow the course of the dotted lines (which show the direction of the right club only; the left club takes a corresponding course in the opposite direction). Keep the hand close up to the chest, almost touching it in fact. You will observe that the club describes a *small* circle from the centre of the chest, and is then swung completely round at arm's length to make the *great* circle.

Something About Pets.

DOGS and other animals are very variously affected by musical sounds; some manifesting dislike, others enjoyment when within hearing of music. "I knew," writes a correspondent, "one dog that, when requested to sing, would stand on his hind legs and go on whining and howling for almost any length of time, and while the performance was attended to he manifested great enthusiasm. But he also enjoyed real music very much, and showed signs of pleasure when the piano was played, getting as near to it as possible. Occasionally, however, he would *take a part* without being invited, much to the discomforture of a singer, who would wonder where the extraordinary accompaniment came from. I have a lively recollection of his volunteering assistance when we were singing a hymn one Sunday evening, and of the way in which it was brought to an abrupt conclusion, by the sight of our doggie on his hind legs, and the sound of his whines ringing out above every human voice."

A pug dog, a great pet, has a favorite tune which he distinguishes from all others. Nugget is a musical animal, and has a way of putting in occasional notes of his own when his mistress plays the piano. But when she commences *his* tune, Nugget becomes greatly excited. He first capers up and down the room, and then, running to the side of the player, he stands on his hind legs and accompanies the music in a style peculiar to himself and most amusing in its effect on the listeners.

Nugget's mistress or any other performer may play the piano by the hour, and the dog manifests only an ordinary amount of interest. But no matter how suddenly *his tune* may be introduced, Nugget shows his appreciation of it by going though the performance already described.

The lady attributes the dog's fondness for the tune to the fact that when he was a puppy her little niece used to play it upon the piano, singing only the word "Nugget" again and again to the music. As, however, the pug recognizes the tune itself, when simply played, from all others, it is quite evident that he has a musical ear, and is not in any way guided by words.

The question is often asked, "Do dogs understand what is said?" and to this everyone will reply, "To a certain extent they do, as is shown by their obedience to their master's commands."

"He can do everything but talk," is a not uncommon remark of a dog-lover, as he pats the shaggy head of his four-footed friend and companion.

Still no one will assert that dogs understand an ordinary conversation, though they undoubtedly often listen attentively when they are fond of the speakers, and obtain bits of information from detached words.

More than this, they obey signs in a stealthy fashion, and move as if they were

treading on eggs, thus showing that they look upon a signal as an injunction to secrecy, and act accordingly.

In proof of this the following is told of the doings of an English terrier.

"Brisk has been unfortunate enough to offend her master. Being in want of something to do she gnawed the leg of a handsome chair, and was chased out of the dinning-room in consequence.

Having been accustomed to spend a good deal of her time on the hearthrug, she objects to this banishment, and as she is tolerated there when the master is absent, she is always on the look out for his departure in the morning.

She will peep in at the dining-room door and look at her mistress, as if to ask, "Is he gone yet?"

Without speaking, the lady will lift up her husband's hat or umbrella, or point to the outdoor boots by the fire-place; when Brisk slinks off again, knowing that if these articles are in sight, the master has not taken his departure yet. As soon as the hall-door closes, Brisk prances in, tail erect, and manifesting her delight in every possible way, she takes up her favorite position.

But, let her mistress rise and place her husband's slippers on the hearth, Brisk requires no other notice. The dog, so to speak, "has had her day," and she at once retires, knowing that the slipper-warming process always precedes, only a few minutes, the arrival of her master.

If the lady when conversing with a friend, introduces the words, "William (William is her husband's name), will soon be home," or, "I believe William is coming," Brisk immediately rises, walks to the door, and manifests great discomfort until it is opened and she can get out of the room.

Yet the lady merely introduces a remark about her husband's return in the course of conversation, and without looking towards the dog or varying her tone. Brisk may be stretched apparently asleep, but she never requires a second warning.

Again, if the lady makes any allusion to her intention of going out when in the dog's presence, Brisk follows her everywhere, dogging her footsteps and never losing sight of her for a moment, lest she should be left behind. But let her mistress say, "I shall take a bus or car," and Brisk gives it up as a bad job and retires to her own quarters sulky and digusted at being disappointed of her anticipated run.

Visitors to Brisk's mistress are often amused by seeing the effect produced on the little animal by these apparently casual allusions, and are convinced that this dog not only pays attention to the conversation, but understands certain portions of it in which she is indirectly concerned, though of the greater part she can comprehend nothing.

There is a very popular belief that some of the movements made by cats are influenced to some extent by "coming events" in the atmospheric world. Good weather, it is said, may generally be expected when cats wash themselves, and the reverse when she licks herself against the grain of her coat, or washes her face over her ear, or sits with her tail towards the fire.

In Germany if it rains when women have a large washing on hand, they say it is a sure sign of the cats having a spite against them, because they have not treated the animals as they ought to have done. This belief is rather a favorable one for the cats, and often, among the working classes, insures for them, better treatment than they might otherwise get.

An enemy to cats may depend upon being carried to her grave during a storm of wind and rain or freezing snow; and in Holland, if the weather is rainy on a wedding day, the saying is, that the bride has neglected to feed the cat. English sailors do not much like to see cats on board ship, least of all do they care to see them unusally frisky or playful, for then they say, "the cat has a gale of wind in her tail." A strange black cat making her appearance in the house is said to be a sure indication of heavy rains and floods. It appears that these cat indications and omens, have no effect unless a she cat is the chief actor. Tommy, it would seem,

is not at all affected by the coming changes in the weather, neither does it appear that pussy has any ill feeling against the sterner sex; for their spites and evil prognostications seem directed more particularly against the gentler half of humanity.

That cats are musical we all know, and though we may not appreciate their renderings, we are frequently forced to acknowledge the strength of their vocal powers. However cats may like their own renderings, it is a recognized fact, that, with but few exceptions, they do not like the musical renderings of human beings; in fact, music and harmony, seem to be sources of great annoyance to them. A writer on this subject, tells the following story which goes to prove that the cat mentioned was not only pained by hearing the music, but that also, she had intelligence enough to make her feelings on the subject known:

"A black cat belonging to a friend, in whose house I was a guest some years ago, had a strong dislike to music in every shape, but especially to singing. Having noticed this peculiarity, I am afraid I teased poor pussy a good deal by my endeavors to produce a manifestation of her feelings with regard to vocal music, and when she was stretched comfortably by the fire I used to begin to sing, taking care to shut the door first. Puss would jump up, rush to it, and finding the means of egress cut off, would run wildly round the room as if in distress until I ceased. Not to irritate the creature too much, I generally made my vocal performance a very short one.

On an exceptional occasion I thought I would try the cat's powers of endurance a little longer, and went on singing, when, after vainly trying to escape, the creature sprang at me, placed one paw across my mouth, and clung to my dress and neck with the rest of her claws in such a fashion that I was only too glad to cease my song and so pacify the desperate animal.

When pussy's claws were disengaged I was not a little relieved, and I need hardly say that this was the last time I ventured to experiment on the cat's patience. My friend was also much alarmed, and I have no doubt thought, as I too did, that I had escaped almost better than I deserved, under the circumstances, for I had only a few scratches.

Winter Rambles.

BY A. W. ROBERTS.

BEFORE I was fifteen years old I took my first lesson in skating. Oh! what a bitter day it was, so cold that I was the only boy on the pond.* I stood it for an hour, and as none of my schoolmates came to bear me company, and my feet had become very numb with the intense cold, I determined to take off my skates and go home. So, sitting down near a clump of elders, I was soon hard at work tugging away at the frozen straps, through which numerous wooden wedges had been driven for the purpose of tightening them up, for it must be known that the boys of those days did not have as much pocket-money as those of the present time—in fact, one pair of skates had to do duty for an entire family, and I was wearing, or trying to wear, my big brother's old-fashioned "turn-ups." The beautiful strapless American skate of the present time was not known then.

"Oh! bother these big, clumsy old skates, with heel straps, toe straps, and instep straps. Will I ever get them off before I am frozen stiff? If I could only find a stick and a stone, I'd drive those wedges out mighty quick!" I exclaimed. Turning to the clump of elders, I broke off a stick, after which I began searching in the dry grass for a stone. By this time my limbs were aching so severely with the intense cold that it was all that I could do to keep back the tears; yet, strange to relate, in the midst of all my pain and trouble I captured my first and most beautiful of all the fairies of the woods, hedges, and meadows, who was wrapped up in hundreds of yards of beautiful soft silk, into which and

* At the time referred to, this pond occupied the exact spot where is now situated the Union skating-pond of Brooklyn, E.D., in a large tract of woodland known as "Johnson's Woods."

through which were woven brown leaves of grass and daisy stalks, the whole being securely fastened to a thorny blackberry cane, that fairly bristled with savage and vicious-looking thorns, as if to afford her protection from harm. Of course I was too inexperienced to know how beautiful, exquisite, and wonderful a creature was enclosed within the warm and waterproof wrappings of silk, but sure I was that I had become the possessor of one of the secrets of the wonderland of the woods, the fairyland of Nature. In an instant my aching limbs were forgotten, quickly were my feet released from the skates, and, on my hands and knees, I was closely examining the elderberry and blackberry bushes for more of these strange objects. My search was not in vain, for when I returned home I carried with me nine of these mysterious creations.

After supper my strange "finds" of the day were spread out on the table, and the entire family were called to inspect them and decide what they might be. One thought they were the nests of some variety of giant spider, another that they might be the winter quarters of bats, or that they were the nests of hornets or some other equally undesirable insect. My big brother, who was studying surgery, suggested the propriety of dissecting one of them, and by this means find out what sort of an animal lived within. "What! cut one of them into pieces and destroy it? Kill it just out of idle curiosity? No, indeed!" I exclaimed, at the same time gathering them up hastily, fearing he might be tempted to put his suggestion into execution. One point they were all agreed on, viz., that I had better keep them in the hay-loft of the barn, and under no consideration in my bedroom. Now, you must know that I had not the slightest intention of hanging them up all winter in the cold hay-loft, for be it known I had kept in my bedroom for many weeks a box that contained a live garter-snake, with her ten baby garters; little beauties they were, too, ranging from three to four inches in length. Gracious! how they could eat grasshoppers and May beetles! Now, if Nora, our servant-girl, had known of this, it would be the last time she would enter my room, and I would be ordered to make up my own bed and take care of my room for all future time to come. In this room was a large closet, of the top compartment of which I was supposed to be the entire owner and occupier, it being so high up that no one cared to claim it. Secretly I determined that in this closet these silken mysteries should be kept. So here all winter long they were watched over and guarded with jealous care, but instead of nine of them, I had increased the number to twenty-four, having made several journeys to the woods in quest of them. The winter months had passed away, and the season of bursting buds and the return of Nature's sweet-voiced musicians had come; bunches of wild flowers stood on my window-sill. Going to bed early was no longer the order of the day. So it came to pass that on one moonlight night, after having retired, I remained awake for a time, planning out my Saturday's wood-ramble. Happening to cast my eyes towards the window, through which the moonlight was flooding the room, I was astonished at beholding what seemed to be hundreds of bats flying outside of the window. Was I frightened? Oh, no. I got up, determined to investigate and solve this curious phenomenon. Well, inside of the room were what appeared to be some ten or twelve bats endeavoring to make their escape out of the room through the window, and outside were some twenty or thirty of the same creatures dashing against the window-panes, as if determined to gain an entrance and rescue their imprisoned friends.

Exactly what to do I did not know. I was afraid to raise the sash, fearing that those inside would join their friends outside, and so I would lose all of them. With a scap-net, which fortunately I had hanging in my room, I captured one of the flying objects, which proved to be a variety of the largest and most beautifully-colored and marked of all butterflies that I had ever read of or expected

to possess. Long and silently I watched them as they constantly charged and dashed against the glass of the windows. Evidently they could see one another through the glass, or were possessed of some other means of communication.

It took me some time and much trouble to capture and confine in my closet the flying beauties that were in my room, after which I boldly lowered the upper sash of the window, when in flew all those that were outside. Quickly closing the window, they were safely imprisoned. Fearing that those confined in the closet might injure themselves, I released them. Well, it was a beautiful sight, this bedroom full of butterflies. I sat on my bed and watched them circle and float about in graceful curves, and when they passed through the bright moonlight, it was assuredly a fairy scene from the fairyland of Nature. For an hour I remained perfectly quiet, so absorbed was I in wonderment as to how this curious event had come to pass. At last I was aroused from my reverie by becoming conscious that the atmosphere of the room was being charged with a very peculiar and penetrating odor; it was not absolutely disagreeable, but was certainly very oppressive, and it seemed to me that as the mysterious odor increased, the butterflies seemed to divide into couples as they continued their merry moonlight dance. At last the odor becoming so oppressive, I remarked to myself, "A. W. R., don't it strike you this atmosphere is becoming a little too tropical? Hadn't you better lock your door on the inside, get out of the window, slide down the kitchen roof to the garden, and take a sleep with the cows to-night? Mark you, it will never do to go down the stairs, for there's two that squeak dreadfully when trod upon after ten o'clock at night." This being the true state of affairs, I turned to the window from out of which I intended to make my exit, and was astonished at beholding almost as many butterflies fluttering about the outside of the window as was contained in the first congregation that I let into the room only an hour before. "Oh! come in, come right in; don't be bashful, odorous fairies of the moonlight! Take full possession of my bedroom, and have a good time!" I exclaimed, at the same time pulling down the upper sash and letting them in. Then raising the lower sash, out I went. Early in the morning I was up and in my room again; not a soul knew or suspected that I had been "out all night." My room was a sight to behold! On the walls, on the bed-clothes, on bunches of autumn leaves, on rustic-work, were plastered strings and masses of small eggs of a dull yellow color, and in every direction hung the butterflies, listlessly, as if tired or weary, hardly moving a wing. Poor things! if they had not been confined in this room, but had had their freedom, they would have deposited these thousands of eggs on the young and tender leaves of the elder. When I took mother, father and brother to my room to see this wonderful assemblage, and related my adventure of the previous night, they could hardly credit it. I asked them what was best to be done with so many beautiful butterflies. They were unable to advise me, till my brother happened to remember a doctor and druggist who lived near by, and who was quite a naturalist, and suggested that I take a specimen to him and ask his advice on the subject. The result of this interview I will give in the next issue of the Young Scientist.

Casting in Plaster of Paris.

BY MARK MALLETT.

I. *The Material and its Preparation.—The Moulds and How to Make Them.*

SOME knowledge of the art of casting in plaster is essential to those who model, since without it they have no means of giving permanence to their work. There are also other purposes for which it may be both useful and interesting; for casts may be made from various objects, natural or otherwise, and applied, as I propose to show, to practical and decorative ends.

Plaster, commonly termed "plaster of Paris," from having in the first instance been brought to this country from the quarries and works of Montmartre, near that capital, is made from alabaster or gypsum. This mineral, more scientifically known as sulphate of lime, consists

of sulphuric acid, pure lime, and water, in the proportions of 46 of the first, 32 of the second, and 22 of the third.

That quality which renders plaster so valuable in the arts, is its power of setting into a solid body after being simply mixed with water. This, whilst the plaster is fresh from the kiln, it does in a few minutes; but with time and exposure to the air, it gradually loses this power. It sets less and less quickly, and when quite stale refuses to set altogether. Thus, bad plaster may involve total failure and disappointment, to guard against which it is well to buy of a dealer on whose word you can rely.

If you feel any doubt with regard to your plaster, try a little before you begin your work, and prove whether it sets properly or not. If you find it necessary to keep plaster for any length of time, put it in a dry place, and exclude the air from it as much as possible. I have kept superfine perfectly good for three or four years by shutting it in a closely-fitting tin, and then well wrapping it in paper. Fresh plaster is always to be desired; yet if very fresh, one difficulty attends it: it may set so quickly as scarcely to give you the necessary time to use it after you have mixed it. If so, you must bestir yourself accordingly.

There are various methods of making moulds for plaster casting. When a clay model has to be dealt with, the process called *waste moulding* is employed, because the mold is destroyed in the production of a single cast. This method I shall first describe.

Waste Moulding in Plaster.—Let us suppose that the amateur has made a model, such as a panel charged with rosettes or foliage. This will have been modelled on a board somewhat longer and wider than itself, the model being, say, a foot square and perhaps from two to three inches thick. Plaster of a medium quality will do for this work; and be sure and have enough of it. If the supply fails whilst the work is on hand, the moulder will be in an awkward position.

And here let me premise, that though plaster is among the most cleanly of substances, odorless in itself, and a neutralizer of all things that have bad smells, it has a tendency to get splashed about and trampled upon floors, in such a way as to make a mess, and to rouse the temper of good housewives; for which reason it is well to practice casting in some workshop or back-kitchen, rather than in an ordinary living room.

Having laid the model flat on a table, its surface must be damped. Sculptors use a syringe, pierced with minute holes, for throwing water in the form of fine spray over their models. Such an instrument the amateur will not possess; but he will have what, for small models, does still better—his mouth. Fill your mouth with water, and after two or three trials, you will find that you will be able to blow it out in a cloud of fine spray. Blow a mouthful of water in this way over your model. Nothing else will so well prepare it for the reception of the plaster mould. In no other way can you damp the whole surface so regularly, without over-damping it, and causing water to run and stand in deep cuttings and hollows, where, mixing with the plaster which is to form the mould, it would tend to soften and injure it.

For reasons which will appear by and by, it is desirable that the first or inner mould should be tinged with color. Various coloring matters are used, according to the whim or practice of the moulder. Many use yellow ochre; but this and similar pigments have a tendency to soften the plaster, which is objectionable. Nothing is really better than common ink, the tendency of which is rather to harden the mould than otherwise, and of this less will suffice than of anything lighter in hue.

Before you begin to mix plaster, it is advisable to tinge as much water as you will want for your inner mould—say a quart in the present instance. Remember that it is merely to be tinged—that it is to have so much color only as will enable you to distinguish readily the plaster mixed with it from that mixed with plain water. If you put more color than this, you will run the risk of staining and disfiguring the cast itself.

We are now ready for mixing the plaster. Two-thirds fill a basin with the colored water, and then begin to sprinkle in the plaster. Do this with the hand, that you may detect any lumps that it may contain; and should you meet with any lumps that do not crumble readily, throw them aside. As you sprinkle the plaster over the surface of the water, it will gradually become saturated and sink. This method of mixing is superior to any other, because the air contained in the plaster is thus driven out, and not imprisoned, and so does not form bubbles, which would injure your work. Go on sprinkling till you see that the plaster no longer sinks, but stands up in hills above the water; this is a proof that enough has been put in. The water takes the proper quantity, and no more.

The mixture must now be well beaten up with a spoon. For mixing superfine, and even fine, if the work is particular, use a silver spoon, as baser metal, particularly iron, may discolor the plaster. Beat quickly but carefully. Beware lest in doing this you beat air into the plaster, and so cause bubbles. There is a way of beating by which the spoon is kept at the

bottom of the basin, and by a quick motion, without bringing its bowl to the surface, the plaster is made to boil up. This is the proper motion to use. As soon as the mixture is of an even consistency, skim off the impurities and those bubbles which in spite of all your care will have formed, and throw them away. When mixed, the plaster will be of the consistency of thick cream. All these operations, which take some time to describe, must be done quickly. No moment must be lost whilst mixing the plaster, or you will have it set before you are ready to use it.

Now, with the spoon, throw the plaster all over the face of the model. See that it goes well into every nook and cranny, or you will have an imperfect mould. Beneath undercuttings you can dash plaster from the spoon. Have a pair of bellows at hand, and with them, by blowing the liquid plaster, you can force it in, and the air out of, the hollows. See that every hair's-breadth of the clay is covered. But whilst you are busy doing this, beware that you do not with spoon, hand, or otherwise touch the surface of the soft clay, or mischief will ensue.

Mix more colored plaster, if necessary, and go on till you have laid a coating a quarter of an inch thick over every part of the model; but do not trouble to leave an even surface: it is better that there should be some lumps and irregularities, which will serve to hold this inner mould to the outer one.

The inner mould is now made, and in making it you will have had to bestir yourself. You may now take breath, and pause for five minutes, at the end of which time you will probably find your mould firm enough for the next process. Mix some modelling clay and water as thick as cream, and with a small brush (a painter's tool) go over the mould. The object of this is to cause the outer and inner moulds to separate readily when required to do so.

The outer mould we have now to make. For this purpose coarse plaster is sufficient. Now and for future operations you will use not colored but plain water. But because you are using coarse plaster, do not mix it carelessly. It is of much importance that plaster should always be properly mixed; and after each mixing it is well to cleanse out the basin, and especially when on the more particular parts of the work, with fine plaster. With coarse plaster it is not necessary to be quite so particular.

A layer of coarse plaster having been thrown or poured all over the mould, and allowed slightly to harden, irons will have to be laid on to strengthen it. As plaster sets and dries it tends to warp, hence the necessity for thus strengthening the mould. Persons who are frequently in the practice of making waste moulds, such as sculptors, keep by them a quantity of thin iron bars of different lengths, and bent in different ways, to use as occasion may require. But any pieces or instruments of iron of suitable size that may first come to hand will do. When I was a student at South Kensington, twenty years ago, instead of the present stately buildings, the Art Schools were mere temporary sheds attached to an old suburban residence, and the kitchen of the former mansion formed our casting room. Whenever a bas-relief was cast, it was noticed that the poker and tongs invariably disappeared—had the gridiron and ladle of the old kitchen still hung in their places they would inevitably have gone into the mould also! In short, any pieces of iron which will stretch from side to side of the mould and prevent warping will suffice. More plaster will have to be poured on in order to imbed them, and the outer mould should thus be brought to a general thickness of not less than three-quarters of an inch.

After an interval of about half an hour the mould will be found to have thoroughly set, and we may now begin to separate it from the model. Where the plaster touches upon the board round the outsides, there will be no adhesion between it and the wood, and the slightest effort will open a chink between them. Into this chink water must be poured, and the mould gently worked up and down with the hand. This will cause the water gradually to work its way between plaster and clay, softening the latter, and if the model is not in very high relief, and there are no considerable undercuttings, with a little patience and frequent pourings in of water, the mould will presently come off. Still it will probably bring some projecting pieces of clay with it, which should be picked out with some of the wooden modelling tools, not with any iron instrument, for fear of injuring the mould. But if the ornament should be in high relief, and the undercuttings should be considerable, this plan will not answer. Instead of it, a string or wire should be passed into the before-mentioned chink, between wood and plaster, and with it the model, mould and all, cut from the board. The string will cut through the soft clay with little difficulty. The mould can now be laid on its back, and the clay dug and pulled out of it, wooden tools and fingers being best to use. Whilst doing this a little water should often be poured between clay and plaster, as it will much expedite their separation.

The clay being by one means or the other removed, the mould must be thoroughly washed with soap and water. A

sponge and a soft brush must be used—not a hard brush, which would scratch the mould. Every trace of the clay must be removed. It is better to clean and fill the mould at once; but if for any reason it should be necessary to lay it by for a day or two, or for a still longer period, during which it will have dried more or less, it must be thoroughly soaked before the plaster is poured in. Otherwise, cast and mould will adhere so closely together that it will be difficult to get the latter off. When the mould is freshly made there will be no danger of this. To hardened plaster, partially saturated with water, liquid plaster adheres firmly; to that which is dry, less firmly; to that which is completely saturated, it sticks so slightly as to be easily separated.

(To be continued.)

Our Girl's Department.

This department is intended exclusively for "Our Girls," and we hope to make it both interesting and instructive, and to this end we ask our young lady readers to assist by contributions, suggestions, or illustrations. There are thousands of little things that can be, and have been, made and done by young ladies, pertaining to decorative art, needle-work, etc., etc., that would be gladly followed but for a want of knowledge on the subject, and we know of no more pleasing task for a lady than that of teaching her younger sisters that which they are anxious to learn, and which may prove of real benefit to them in the future, as well as being useful and interesting for the present. We trust we will have no difficulty in persuading those who have something nice to show or speak of, to make use of this department. Remember, it is open to all, and if you have anything worth knowing suitable for this column, send it along, and we will give it our best attention. Do not be afraid to write because you may fancy your composition is not perfect, or have other scruples of a similar kind. Do the best you can, and leave the rest to the editor of this department, and we are sure you will be pleased with your work.

PRAISE not people to their faces to the end that they may pay thee in the same coin. This is so thin a cobweb that it may with little difficulty be seen through; 'tis rarely strong enough to catch flies of any considerable magnitude.—*Fuller.*

—A wise woman reflects before she speaks; a foolish one speaks, and then reflects on what she has uttered.

—It is a curious fact that children are the best judges of character at first sight in the world. There is a Scotch proverb, "They are never cannie that dogs and bairns dinna like," and there is not a more true one in the whole collection.

—We are ruined not by what we really want, but by what we think we do; therefore, never go abroad in search of your wants; if they be real wants they will come home in search of you, for she who buys what she does not want will soon want what she cannot buy.—*Colton.*

—The broad, low dressing-table with tiled top and swinging glass is now the desideratum in every lady's boudoir.

—The latest menu cards represent lily leaves or flowers, without a margin, and have the name inscribed in gilt letters.

—The ugly carpet ottomans have been superseded by the old-fashioned foot-stools, with square frames and embroidered cover.

—Table glass has become almost infinitely diversified in form and color, but the rose pink and pale yellow are preferred for decorative effects.

—Fashionable window shades are of cream-colored linen, with a bordering of drawn work, and are finished off by knotted fringe cord and tassels.

—A beautiful ornament for the centre table is a large crystal ball mounted upon a small spiral pedestal. It catches and reflects the light, and forms a wonderful radiator.

—Nobody buys white crockery now-a-days or the white China with the dreadful gilt band, which gradually wore off into the tea a few years ago. Why cannot the hotel and restaurants get rid of their "brutal" white stoneware?

—Painting on chamois leather in silver and gold is a novel style of decoration, especially suitable for handkerchief-cases, glove-boxes, or scent-satchels. The chamois cleans well and takes color beautifully.

—An umbrella and cane stand is formed with a frame work of wood, and a case attached, which is of pasteboard, covered with plush, handsomely embroidered, or with one tapered cylinder front and two small ones at the back for canes.

—The fashionable style for portieres is not to have them hung from rings from the pole, but thrown over it in such a way that one side shall turn back and fall

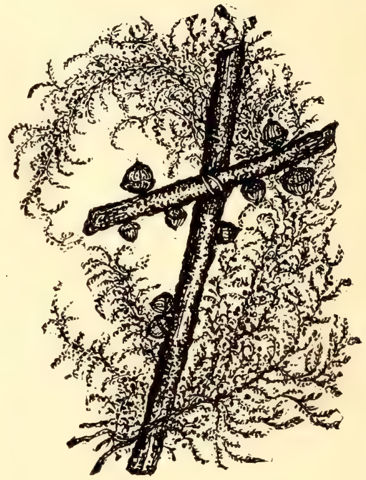
over in the shape of a valance. When well done, this fashion of hanging is graceful and effective.

— A lady now teaches the Metropolitan Museum, New York, day class in decoration for women, with the use of tempera or body-color in the artistic decoration of leather, silk, satin and glass, to which is added a course of drawing, and the use of color in preparing designs for industrial ornamentation.

— A novel decoration for the unsightly transom windows which disfigure so many rooms in city houses, is made by filling in the space with deep-colored damask paper, upon which handsome raised paper figures are laid. The figures, which are of every variety, can be bought singly for 25 cents at any of the leading wall-paper and decorators' establishments.

— Miss Ellen H., Brooklyn, sends us the following seasonable suggestions, which will doubtless be of service to many of our lady readers: "In decorating the church for Easter, arrange your flowers with regard to the effect from a distance. Choose characteristic flowers rather than those hothouse beauties which we can get all the year round. No flowers are more effective than the Easter lilies (L. candidum and longiflorum). The passion-flower comes next, and where smaller flowers can be used, hyacinths, crocuses, narcissi, primroses, violets, lilies-of-the-valley, and snowdrops supply both beauty of form and delicate coloring; the fresh pinks, lilacs, and primrose yellows of the true spring flowers are, I think, quite in place. For green, nothing is better than ferns, and for draping, English ivy and passion-vine; where *lightness* is needed, sprays of acacia will give the desired effect. Palms are good, but the list of pot-plants suitable to be used where elaborate decorations are intended is too long to enumerate here."

— As ornamental cards of all kinds are very fashionable just now, perhaps some of our young lady readers would like to make something novel and artistic in that line. The illustration shows how an ornamental card may be made by utilizing some of Nature's simple productions. Procure a neat white or gray pebble card of suitable size for a background; then take two slips or bits of twigs of any of our dwarf oaks, to which are attached a few of their small, but beautiful brown acorns. The twigs should be split down about one-half, which can readily be done



with a knife. This will leave the twigs half-round, with one side flattened, which will be the side to gum or glue to the card. Draw a cross or other suitable design, with a pencil, in very light lines. Cut the twigs to conform with the lines drawn; gum them fast to the card, being careful that the gum or glue does not spread on the paper. When fastened on and dry, surround the design with a nearly circular wreath of wood mosses or lichens, among which place here and there, as taste may suggest, a few heads of the bright crimson "sealing-wax moss" (lichen). The mosses, of course, must be fastened in place with the smallest amount of mucilage or glue possible, and they may be arranged to suit the taste of the maker. Such a combination of natural materials, when tastefully applied, exceeds in artistic beauty many of the fancy cards that are found in most of our stationers' shops; and to those who have a taste in this direction, the making of such cards is a gratifying and pleasing pastime.

Published by

THE INDUSTRIAL PUBLICATION CO., 49 Maiden Lane, New York.

Will those of our subscribers who receive two copies of the YOUNG SCIENTIST, kindly hand the duplicate to some friend interested in such matters, and thus perhaps aid us in securing a new subscriber? Remember that every additional name enables us to improve the Journal, so that all have an interest in adding to the number of our subscribers.

Contributors to the YOUNG SCIENTIST will help us along very materially by sending in their communications on or before the tenth of the month preceding the date of issue, as we go to press about that time. Wherever drawings or engravings accompany the communication, they should be sent in at least ten days earlier than the time mentioned above, as it takes from ten days to two weeks to get the cuts made from the drawings. We hope our young friends will make a note of this, and send in their always welcome contributions early enough to insure their publication on time. We have found it necessary to make the foregoing remarks from the fact that several excellent communications and drawings came in for this issue, but were too late, and they are of such a character as to be of no service next month.

Although we do not place much faith in the sayings of Wendell Phillips, when giving utterance to opinions of his own or propounding theories from his inner consciousness; but when he makes an assertion, and states it as a fact, he commands our attention at once; and when he states definitely, and without qualification, that ninety-nine per cent. of the graduates of our colleges are never heard from as successful business men, and backs his assertion with apparent facts and figures, we are astounded, and wonder if some mistake has not been made. Can it be possible that this assertion is true? If it is, what becomes of this ninety-nine per cent.? Are the hundreds of M.D.'s, A.B.'s, A.M.'s, LL.D.'s, etc., that are yearly turned out by the great colleges of this country, useless appendages or worse to society? If not, where do they all go to, and what do they do? These queries are worthy of consideration, particularly so to parents who have boys approaching man's estate; for if it is true—and there are some reasons for thinking it is—that only one boy out of every hundred sent to college becomes a successful business man, fathers should hesitate before sending their boys to colleges. If parents have plenty of means, and their children are likely to inherit them, then it may be well to give the young people the highest education attainable, and this, we think, can best be done through our colleges.

We have no hesitation in saying that our technical schools and institutes offer better facilities for acquiring knowledge of a practical kind, and which will prove of greater pecuniary value to the aspiring youth, than can be obtained from a purely classical training. This is a matter of considerable import to boys who will have to make their own way in the world. We do not wish it understood that we undervalue a college training; on the contrary, we wish it were possible for every boy in the country to obtain such training, but we must say that we are of the opinion that a thorough technical training in some school where the boy is brought face to face with the stern realities of life, will be of immeasurably greater value to

him—and to the State—than all the Greek and Latin lore of bygone ages would be. Most of the useful and successful men of the present and past ages received their training outside of college walls, and under circumstances that fitted them for the active lives they were destined to pursue. A thorough scientific course with relation to the arts must naturally conduct the mind into logical grooves and prepare it to grapple successfully with the hard facts and problems that are continually developing, and the parents of a boy who bends his energies to the acquisition of mechanical and scientific knowledge, need have no fears for their boy's future. Depend upon it, the mind that has grasped the various problems and their solutions that are connected with the mechanical sciences, will not only hold its own in life's battle, but it may safely be said of it that success and prosperity will rise at its bidding.

When you have a valuable pattern for scroll-sawing, and want to keep it good for future use, a good plan to preserve it is to prick it through with a needle or other fine-pointed instrument, as close together as possible. Then lay the pattern on the wood to be sawed and pound it over with a bag filled with fine charcoal dust. Upon lifting up the pattern you will find a perfect duplicate of it on the wood. The pattern may be transferred to white paper by this method, and the lines traced with a pencil, after which the paper with the made pattern may be fastened on to the wood, and the latter will then be ready for cutting. Transferring the pattern to white paper first is much the cleaner and better way.

Another and a better way to transfer a pattern is to take a plain sheet of writing or printing-paper; lay it on a table or other flat surface. On this place a sheet of good transfer paper (black is best), and then the design; fasten with tacks or drawing pins; then, with a fine pencil or other pointed tool, trace carefully around the design, and when finished a good plain copy will be found on the white paper, and the original design unhurt. In applying this design, a good way is to use a small quantity of ordinary mucilage. After the work has been cut and completed, the design may be removed by damping it with a moist cloth or sponge, and may be used again if desired. Should the wood become damp in taking off the pattern, it should be placed between boards weighted down, to keep it from warping. When dry, it may be taken out and used for what it was intended.

Scientific and mechanical amateurs are invited to send communications to this office with regard to the various problems they may be working out. Advice and assistance will be gladly given through our columns on any scientific or mechanical subject that may be within the range of amateur experiment, providing it is of such a character as will prove instructive or interesting to the majority of our readers. It will give us great pleasure to answer any question relative to the scientific, mechanical, industrial, and decorative arts in our column of "Notes and Queries," and we trust our readers will not be afraid to make use of this department. If you have any little mechanical or scientific difficulty, let us know of it; some fellow reader will probably be glad to relieve you and render great assistance to many others, by publishing such information as could not be otherwise secured, or we might help you amazingly by offering such advice and suggestions as our large experience might warrant. While we do not wish to make the department of "Notes and Queries" general, we have no objection to the admission of questions and answers that are not strictly scientific or mechanical, but which partake of a practical and useful nature. There are many things boys and girls want to know about birds, dogs, cats, rabbits, goats, white mice, guinea pigs, gold fish, and other pets that may safely be submitted to this column. It frequently happens, too, that girls may want to know something regarding their own special class of work, such as knitting, embroidered and other fancy needlework, or they may wish to know something of the treatment of window plants, flower-gardening, and many other things of a

like nature. Any questions of this kind, when requiring answers that will be generally interesting or instructive will be cheerfully replied to, either by ourselves or correspondents.

The parents who have wisdom enough to appreciate and cultivate the mechanical interests common to most children, go a long way towards insuring their success in after life, for fingers trained to works of skill are not likely to be afterwards found idle. The development of mechanical desires and tendencies in children should be encouraged by every one who wishes them well now and hereafter. From a worldly point of view, the cutting and whittling instinct in a boy or girl represents a money value of considerable magnitude, and the parent or guardian who neglects to aid the growth and development of this valuable trait, is, to say the least of it, grossly indifferent to the welfare of his charge—he owns a diamond in the rough, that would be doubled in value by polishing and setting. All our great constructors, inventors, successful civil and mechanical engineers, mechanical superintendents of our shops, factories, shipyards, and railways, are men who early evinced a disposition to cut, whittle, saw and tinker; and the hundreds of intelligent women in this country who direct the work of the thousands of their less gifted sisters in the various millinery, dress-making, and other establishments where female labor is employed, were ladies whose early tendencies to "scissor," cut, hem, patch, and whittle often caused their parents to wish the "mechanical instinct" had never shown itself. These men, these women, one and all, owe their positions, in a great measure, to their "mechanical instincts," and here is where the money value lies. The man who, by his superior knowledge and intelligence, commands from fifty to one hundred per cent. more for his services than his neighbor, owns a property of great value, and one that is not subject to many of those mutabilities which often, without warning, sweep away the gatherings of a lifetime. Give the children tools—boys and girls—mechanical toys, books, and simple scientific instruments, and, where possible, a workroom. Let them cut and whittle to their hearts' content. Give them the benefit of your knowledge of mechanical matters as you would of any other thing that you think would be of use or interest to them. Lead their efforts on to pleasing and useful results, and you will lay the foundation of future usefulness and competency. The YOUNG SCIENTIST has special claims on parents and guardians, and if introduced to their charges in a proper spirit, will assist in developing a taste for mechanical and scientific research that will not only possess a money value of great extent, but will tend to divert the minds of the little ones into grooves that will ever after prove their moral safeguards.

The Planets.

MARCH, 1883.

(All Computations are for the Latitude and Meridian of New York City.)

Mercury will be visible for the second time this year March 3-6, being at greatest elongation on the 3d, and brightest for three days thereafter. The elongation being western, Mercury will be a morning star, rising before the Sun, and at a point somewhat south of the sunrise point. This will not be as favorable a time to see him as at his next elongation, May 14. He rises on the 5th at 5h. 29m., just one hour before the Sun, and will therefore be visible for a few minutes.

Venus will be stationary on the 26th, and she will vary but very little in her time of rising throughout the month, being at 4.17 A.M. on the 10th, and 4.12 A.M. on the 25th. She will be 3° south of the Moon on the 5th, being near the cluster of stars marking the head of the Goat. She now presents a slightly gibbous phase, which will gradually approach a complete circle as the summer months pass.

Mars will continue to be a morning star until next November. He is still a very late riser, receding from the Sun very slowly, and rising about 6 o'clock in the morning.

Jupiter reaches his eastern quadrature on the 13th, still shining with great lustre. The great Crab Nebula is just to the right or west of him, and about 1° above the third magnitude star *Zeta Tauri*, which, with the third magnitude star *Beta Aurigæ*, marks the tips of the Bull's

horns. Jupiter is completely surrounded by interesting and beautiful objects. The Seven Stars, or Pleiades, Saturn, and the Hyades, are upon the west or right; Capella, the Kids, and the Segment of Perseus north of him; Castor and Pollux, and the other bright stars of the constellation Gemini, with Cancer and the faint little cluster of stars called Præsepe, are to the left. Near Præsepe is a very noted triple star, *Beta Cancri* or Tegmine by name. This star may be readily found by being pointed at by Castor and Pollux, and at double their distance apart from the latter. Two of the members of this system perform a binary revolution in about sixty years, and the other performs a grand orbital ellipse in five or six hundred years. This and many others go far to verify the theory that each star of the firmament is but the central member of a solar system similar to our own. Suppose an observer situated outside of our system, at a point sufficiently distant as to render all but the Sun invisible to the naked eye, and the Sun reduced in apparent size to the grade of a second or third magnitude star. Then, with a powerful telescope, he would see the two giant and partially self-luminous planets, Jupiter and Saturn, as attendants upon the star, making a triple star. Thus all star systems, binary, triple, quadruple, and septuple, would seem to be but visible portions of large systems having a common centre of gravity. Orion is between Jupiter and the southern horizon, Betelguese (pronounced Be-del-gæze ?) being nearly midway between Jupiter and the King or Belt of Orion.

Eclipses of Jupiter's satellites may be seen in the early evening hours, as follows: March 5th, 9.51 reap.; 13th, 9.10 reap.; 21st, 8.11 reap.; 28th, 10.7 reap.; 31st, 7.8 reap. It will be interesting to witness the *entire* eclipse of the fourth satellite on the 18th, beginning at 10h. 40m. 29s., and ending at 11h. 39m. 13s. The following Jovian events will also be visible in the evenings of March:

Occultations.

Sat.	*D.*	*H.*	*M.*	
III.	2	7	3	disap.
III.	2	9	48	reap.
I.	5	6	18	disap.
II.	27	9	6	disap.

Transits.

Sat.	*D.*	*H.*	*M.*	*Phase.*
I.	4	9	5	ingress.
II.	4	9	22	egress.
II.	11	9	13	ingress.
I.	13	7	43	egress.
I.	20	7	22	ingress.
III.	20	7	54	egress.
I.	20	9	38	egress.
IV.	26	7	55	ingress.
IV.	26	8	0	egress.
III.	27	9	11	ingress.
I.	27	9	20	ingress.

It will be seen that on the 26th, Sat. IV. makes a transit occupying only five minutes. These events are of rare occurrence, this being the only one visible until next September. The apparent semi-diameter of Jupiter at the time of this transit is about 18″, while the distance of the fourth satellite south of the major axis of the ellipse in which the satellite moves is 17″. It will thus be seen why the transit is of such short duration.

Saturn is in the eastern part of the constellation Aries, where a line from Sirius, through the Belt of Orion or the Kings, will touch him, when produced as far again. He will be 1° south of the Moon on the 13th, and sets on the 10th at 11h. 4m. eve.; 25th, 10h. 12m. eve.

Uranus arrives at opposition on the 12th, and will be brightest at that time, being readily picked up by good eyes. He presents no phenomena of interest to the telescopist, not even his four satellites being visible except with the very best telescopes. Every person, however, who knows anything at all of the heavenly bodies, should be able to say that they have seen all the planets visible to the naked eye.

Uranus passes the meridian as follows:

March	5	0	40	morn.	Dec. 4° 4′+
"	15	11	55	eve.	Dec. 4° 15′+
"	20	11	14	eve.	Dec. 4° 25′+
"	25	10	50	eve.	Dec. 4° 31′+

Look for him on a line between Regulus and Spica Virginis, and just about midway between them. The third magnitude star *Beta Leonis* is very close to him, being but one degree north.

EPHEMERIDES OF THE PRINCIPAL STARS AND CLUSTERS, MARCH 21, 1883.

		H.	*M.*
Alpha Andromeda (Alpheratz) sets		7	57 eve.
Omicron Ceti (Mira) variable	"	8	5 "
Beta Persei (Algol) variable	"	0	38 mor.
Eta Tauri (Alcyone or Light of Pleiades) sets		11	12 eve.
Alpha Tauri (Aldebaran) sets		11	30 "
Alpha Aurigæ (Capella) in merid.		5	12 "
Beta Orionis (Rigel)	"	5	13 "
Alpha Orionis (Betelguese)	"	5	53 "
Alpha Canis Majoris (Sirius or Dog Star) in merid.		6	44 "
Alpha Canis Minoris (Procyon) in meridian		7	37 "
Alpha Leonis (Regulus) in merid.		10	5 "
Alpha Virginis (Spica) rises		7	59 "
Alpha Bootis (Arcturus) "		7	2 "
Alpha Scorpionis (Antares) rises		0	9 mor.
Alpha Lyrae (Vega)	"	9	42 eve.
Alpha Aquillae (Altair)	"	1	22 mor.
Alpha Cygni (Deneb)	"	10	45 eve.
Alpha Pisces Australis (Fomalhaut) invisible.			

Penn Yan, Yates Co., N. Y.

How to Drive a Nail.

The following notes contain information that is familiar to all experienced workmen, but is probably new to many of the readers of the YOUNG SCIENTIST. We take it from the excellent catalogue of Bee-Hives and other Apiarian Supplies of A. I. Root, of Medina, Ohio:

"Much depends on having a hammer just right for the work that is to be done. I often see people (women especially, begging their pardon) try to drive a small, slender nail, into light work, with a very heavy hammer. The nail doubles up, the work splits, their fingers get pounded, and it is no wonder they conclude in disgust that carpentry is not their forte. Trying to drive a large nail with a light hammer is not so bad, but it is a great waste of time and strength. Every bee keeper should have at least three sizes of hammers. You can drive a common brass pin its whole length into a pine board with a hammer of the right weight; but should you try to do it with a hammer that is too heavy you would double it up the first clip. In watch work, we frequently require hammers weighing scarcely more than a quarter of an ounce."

Novelties for Amateurs.

We intend to reserve this department for the description and illustration of such tools, appliances, instruments, devices, and methods, as may be brought to our notice, and that we think will be of use or interest to our readers. Whatever may be brought under discussion in this column will only receive the views of ourselves, as we do not intend to be biased by interest or by the sayings or offers of manufacturers or inventors. In other words, we do not intend to be bribed by advertising or other patronage to praise or condemn an article, if, from our point of view, it does not deserve such.

If we think an article good, we shall not hesitate to say so. The same rule will obtain if the article is not such as represented. Indeed, we shall feel it incumbent upon us to keep the readers of the YOUNG SCIENTIST informed of all inventions, devices, etc., etc., that we may be advised of, and that may be of use to them, and to warn them against purchasing the "cheap John" and "catchpenny" stuff that is so freely advertised all over the country.

Of course, we shall be pleased to receive samples of tools, instruments, materials, or anything suitable for the young experimenter or amateur worker, for examination, and if they are such as we think will be appropriate for use to any of our young readers, we shall gladly give a notice thereof, and illustrate, where necessary, showing up their good features and pointing out their defects.

No doubt there will be cases where our obtaining a specimen will be out of the question, as the articles may be too large or too expensive. In such cases, "Mahomet will go to the mountain," but we shall see to it that our readers do not suffer in consequence. Now, in every notice that may be written of any article, be it what it may, it is our intention to give all the particulars we can obtain regarding it, fully and clearly, believing it to be in the interest of both buyer and seller that this should be done. That there are those who are averse to this method, we are fully aware, as they think that publishers or editors must derive some benefit or other by saying all about an article, its price, and where and of whom it is to be bought. Such a supposition is as absurd as it is groundless; the publicity that is accorded to any article is, after all, in the interest of those who may be inclined to buy, rather than that of the makers and sellers; and of those who would infer that the submittal of any manufactured article for notice inclines the person who has to weigh its merits to decide in its favor, we would ask if they would think for a moment that the sending of a book for review has anything to do with influencing the opinion of the reviewer? And as with book reviews, so is it with notices of articles composed of other materials than paper, cloth, and pasteboard.

Having thus defined our position, and endeavored to show that neither publishers nor editors do or can derive any benefit from the notices of articles, we may point out to inventors and makers that any article they may send to be examined and tested shall receive fair and impartial consideration. Examination and test are as necessary to the review, so to speak, of a plane or saw as of a book, or of a drilling-machine as of a periodical; taking this view of the matter, we trust that manufacturers and makers who desire to have their specialties mentioned in the YOUNG SCIENTIST will send their articles at an early date, so that we may have ample time to do justice to the subject.

Visitors to the American Institute Fair, New York City, last fall, no doubt saw, in the entrance leading to the Art Gallery, several specimens of the Gate's Folding-Table. These tables are certainly very ingenious contrivances, being so small that they may be used for a writing-desk, as they can be tipped to any angle to suit the writer. They may also be made to answer as a book-rest, as the top is provided with a movable ledge, which may be attached near the lower edge of the table top when it is tilted.

and which prevents the book from sliding off. The adjustment for regulating the height of the table is very complete and effective. The central post is formed of two parts, and is made of metal nickel-plated; the upper half drops into the lower part, and which contains a strong spiral spring, which forces the top to the required height, where it is firmly held by a screw-clip. A little pressure on the top of the table will force the top down, when it may be securely fastened. When the table is not in use, it may be folded up, legs and all, and laid away in any place, with the face of the top against the wall.

The dimensions of the top are 30x23 inches, just the size required for a small drawing-table or for a game-table. Perhaps the amateur or scientific student who is hemmed-in by narrow limits, and who has not time or inclination to make a table suitable for his purposes, might find this to answer quite well.

The Challenge Scroll-saw, manufactured by the Seneca Manufacturing Co , Seneca Falls, N. Y., has recently been improved to such an extent that it is now one of the best saws available for

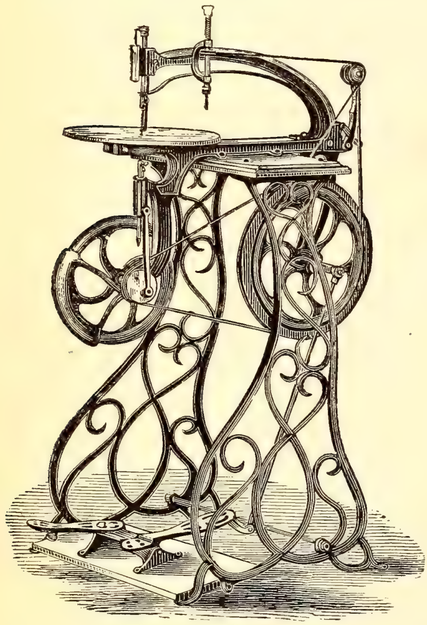

Fig. 1.

executing the finer kinds of work. The engraving, Fig. 1, shows the saw in working trim, with boring attachment, blower and all complete. An excellent feature in this saw is the method in which the table is connected to the saw, which is accomplished by a ball and socket joint. The ball is hollow, and the saw passes clean through it, there being ample room left for the saw to work without interference. The main object of the ball and socket joint is to enable the sawyer to tilt the table to any desired position for sawing inlaid work or cutting material on a rake. The table is held in position

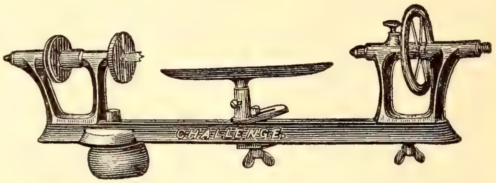

Fig. 2.

by means of a clamp, which is attached to the joint, and which may be tightened or loosened at will by simply turning a nut which forms part of the clamp.

As a rule, the most unsatisfactory part about a scroll-saw is the device for holding the saw in place. This difficulty has, in a measure, been removed in this machine, as it is provided with an excellent device for holding the saw in a firm grip. A slot is made in the spindle, terminating in a small hole drilled through; a small bolt passes through the spindle below the hole; on the end of the bolt is attached a thumb-screw, which can be tightened or loosened at will. The spindles are made from the best of Hobson steel, and are spring-tempered, so that the saw cannot slip when properly held, or tear or disfigure the spindle in any way.

The slots in the spindles are directly in line with the line of centre of spindles, which insures the true working of the saw, which is a very important matter in scroll-sawing.

The workmanship on these machines is of the best kind, every part of it seemingly as perfect as hands and tools can make, and any part can be duplicated by sending to the manufactory. The capacity of the saw is to cut wood up to one inch thick, and it will take in from fourteen to fifteen inches between the saw and the frame; it is not liable to get out of order with fair usage, and is suited admirably to the wants of amateurs, shell, bone, and ivory workers. Metal may also be cut on this machine, if the plates are not too thick. The saw complete, without lathe attachment, weighs sixty-five pounds.

Fig. 2 shows the lathe attachment for the Challenge saw. It is made of iron and steel; length of bed, 18 inches; distance between

centres, 11 inches, and swings 4 inches; rests, 4 and 8 inches. It has a solid emery wheel for grinding and polishing tools, metals, etc. The head has a spindle of steel, nicely fitted, with face plate, spur centre, etc. The tail stock has a screw spindle of steel, with wheel, etc. It is fastened to the saw frame with the ball and socket joint, the same as used for the tilting-table. The saw and lathe are sold separate.

Our Book Table.

The Empire City Philatelist. A. M. Crouter, Editor and Publisher, 155 West Broadway, New York. Published monthly; 50 cents per year.

This publication is devoted to the interests of stamp and coin collectors. To those of our readers who are making collections of either stamps or coins, this journal would prove of great interest, as it describes the various stamps as they are issued, and contains considerable gossip regarding collections and collectors, sales of stamps, coins, and medals, and newsy chats of doings in the post-office department. Each number also contains contributions and correspondence from foreign countries concerning post-offices, postage-stamps, and old coins. The journal has many other pleasing features, and on the whole is a paper that will well repay its cost to all who are interested in the collection of postage-stamps, numismatics or coin collecting.

Scientific News.

—It has been popularly supposed that the rings of a tree furnished a reliable record of its age in years. But Dr. A. L. Child writes to the *Popular Science Monthly* that this idea is erroneous. His experiments go to show that the formation and thickness of the rings depend upon the changes in the atmosphere, and the more frequent these changes the greater the number of rings. Trees which he knew to be only twelve years old proved, upon being cut, to have thirty-five to forty rings.

—On the authority of Mr. Woodbury, of Boston, it is stated that 40-light Brush dynamos in use at Adams, Mass., require 36 and a fraction horse-power each. The cost of running arc lights in various steam mills, running, when lighted, 400 hours per year, is estimated by him at 6½ cents per hour, of which 1½ cents are for carbon, and 5 cents for coal, attendance, depreciation and interest. When a mill runs nights the hourly cost is considerably diminished. Where arc lights are substituted for kerosene lamps the ratio between the two was, in one case mentioned, one arc light for eight kerosene lamps. These facts are of great importance to manufacturers.

—A late report of a patented method of making artificial wood comes from Germany, where Herr B. Harrass has invented and put into practical operation a process which consists of the manipulation of a mass consisting chiefly of cellulose and starch. Common cellulose, sold in the form of paper, is reduced to pulp in water. To this is added, after being drained through a sieve, three parts by weight of starch and two parts by weight of wheat or maize meal. The compound, thoroughly mixed, is put into tubes of thin metal and boiled over a water bath. When done the allotted time, and turned out after cooling, the mass resembles glue, which is then mixed with the same quantity of sawdust. This mass is rolled and left to dry in a hot room, and is then ready for use. For pressing into the desired shape iron or steel moulds are used, heated to 120 degrees, and the mass is subjected to enormous pressure. After cooling, the article is said to resemble wood, and can be treated in every respect as such, becoming with age bone-hard. It can be worked with the saw or file, can be colored, polished, and, when desired, covered with veneer.

—The cultivation of the singular parasitic shrub mistletoe for ornamental purposes is recommended in foreign papers, and young trees with mistletoe growing on them are offered for sale in English nurseries. It is generally found on the branches of apple-trees, but is not very particular in this respect, and takes its habitation also on different other trees. It may be raised from seed placed in the crevices of the bark of young, healthy branches; or it may be propagated by grafting, in which case, a piece with a portion of the bark of the tree from which it is taken has to be cut with it, and firmly secured to the new position. The European species is larger and rather more ornamental than our native kind, for which reason the latter might not prove a success for exclusively ornamental purposes; but if some enterprising florist should succeed in raising mistletoe in neat hanging-baskets, which might be hung ingeniously over doors and archways under which young people of both sexes have to pass—and older ones, too, for that matter—there might spring up quite a demand for the "novelty" about Christmas-time.

Practical Hints

Holes in Glass.—It is said that a round hole of any desired size may be cut in a pane of glass without injury to the pane by taking a copper tube of the size of the hole required and causing it to revolve in contact with the glass, keeping the surface where the cut is to be made well supplied with emery and water. Of course, care must be taken to hold the glass firmly down and to prevent the tube from moving away from the spot where the hole is to be cut.

Polishes.—The following is said to be a very effective polish:—Dissolve four ounces of orange shellac in one quart of ninety-five per cent. alcohol, and when the shellac is dissolved add one quart of linseed oil and one pint of turpentine. Mix the ingredients, and when thoroughly incorporated add four ounces of sulphuric ether and the same quantity of liquor ammonia. Stir well before using, and apply with a cloth or sponge, rubbing the surface to which it is applied till the polish appears.

Glue-Pot.—There are a great many times when a glue-pot in the house is a "well-spring of pleasure," and is an economical investment, especially when one of the kind here described: Buy at a tin-shop one small tin cup, costing five cents, and a larger one, costing about ten, in which the smaller one can be set; five or six cents' worth of glue will mend a great many broken articles, or will fasten the things that have become unglued. Put the glue in the small cup with a little water; put boiling water in the larger one, and set the glue-pot in it; in a short time the glue will melt and be ready for use.

To Remove Rusted Bolts.—The most effectual means for the removal of bolts that have rusted in, without breaking them, is the liberal application of petroleum. Care must be taken that the petroleum shall reach the rusted parts, and some time must be allowed to give it a chance to penetrate beneath and soften the layer of rust before the attempt to remove the bolt is made. Bolts and studs on which the nuts are fixed with rust are broken off through impatience. In most cases a small funnel built round a stud or bolt end on the nut with a little clay, and partly filled with any of the searching petroleum oils, and left for a few hours, will enable the bolt or nut to be moved.

Distempering Ceilings.—Give the ceilings a coat composed of soft soap, lime, putty, and size. The quantities to be used of each ingredient entirely depend on the finish of the ceiling; some are much more absorbent than others. The soft soap prevents the dry plaster absorbing the color too quickly, so that a clean, even surface may be obtained with the finishing coat. If the workman is not a practiced hand, he may be successful in laying an even coat of distemper; and even if he should succeed, if his ceiling is gray-finished, the sand will probably spoil the distemper. A remedy for this would be to cover the ceiling with lining paper and distemper on the paper, but experience is here also required in hanging the paper. Very little size is required for distemper—just sufficient to cause the color to adhere firmly.

Frosting Leaves.—Alum frosting for leaves is both simple and harmless. Dissolve alum in boiling water, in proportion of a pound to a quart. Pour it into a deep vessel, and as the solution cools, the alum will be precipitated. Choose light sprays, and hang them with the stems upwards on cords stretched across the top of the vessel, so that they do not touch the bottom; the stalks will attract the alum in the process of crystallization like the threads of sugar-candy. The warmer the solution when the sprays are put in, the smaller will be the crystals attached to them, but care must be taken that it be not hot enough to destroy the leaves or fronds; and if there be berries, like holly, it must be hardly lukewarm. The same solution warmed again will do two or three times. If the sprays are frosted some days before being required, they must be kept in a warm, dry atmosphere.

Notes and Queries.

In continuing this department, which has been found of so much value, we would remind our readers who wish for information on any of the arts and sciences, that they are cordially invited to make their wants known through this column, and those of them who can furnish accurate answers to questions asked are requested to send in replies. Doubtless many of our subscribers may know of methods, processes, or devices that may be better or more suitable for the particular case in question than anything generally known, and it is this reason that induces us to keep this department open for a medium, where an interchange of ideas and practices may be made to the advantage of all our readers. Correspondents will please send their full address when forwarding their communications—either questions or answers—not for publication, unless expressly so stated, but so that we may know where to find the writer if desirable. Communications should be sent in on or before the first of each month previous to publication, to insure insertion in next issue.

Answers.

26. MATILDA, Newark, N. J.—There were many curious myths and superstitions believed in by the ancients regarding trees, flowers and shrubs, and it is not surprising that many of the heathen gods were honored by having some of the finer trees dedicated to them. The following is an incomplete list of such dedications:

FLOWERS AND TREES.

I. Dedicated to heathen gods—

The Cornel Cherry Tree	to Apollo.
" Cypress	" Pluto.
" Laurel	" Apollo.
" Myrtle	" Venus.
" Oak	" Jupiter.
" Olive	" Minerva.
" Pine Cone	" Assyrian Temples.
" Vine	" Bacchus.

II. Dedicated to saints—

The Rose	to Mary Magdalene.

III. National emblems—

The Linden (Lime)	to Prussia.
" Rose	" England.
" Shamrock	" Ireland.

IV. Symbols—

The Box, Holly, and Ivy, the	Resurrection.
" Cedar	Faithful.
" Olive	Peace.
" Orange Blossom	Virginity.
" Palm	Victory.
" Vine	Christ our life.
" Yew Tree	Death.

V. Funeral Plants.—The laurel, oak, olive, myrtle, rosemary, cypress, and amaranth.

The juice of the fir tree (turpentine) used to be mixed by the Greeks with new wine to make it keep; hence fixed on the Thyrsus (a pole wreathed with ivy) as one of the symbols of the god Bacchus.

A modern Greek legend invests the holm oak with a very bad reputation. When the crucifixion was about to take place, all the trees met to-

gether and determined not to lend their wood to the construction of the cross. They all kept their word except the holm oak. The other trees broke in pieces when an attempt was made to utilize them for cross-making. The holm oak alone allowed itself to be made use of; wherefore it is looked upon as accursed. Wild chicory has been made the subject of many legends, especially in Germany, where it is known by several names, one of them being *wegewarte*, or road-guardian. The popular explanation of the term is as follows: A young princess whom her beloved spouse had abandoned, declared that she would like to die, but yet she longed to see the loved one again; and the maidens who bore her company expressed a similar desire. Their wishes were realized. They were turned into flowers, white and blue, and stationed along the sides of roads, so as to be able to see the loved and lost prince whenever he rode by. And since that time the plant has been called the guardian of roads.

27. Tom H., Providence, R. I.—The divining rod, or, as it is called in this country, the "Witch-Hazel," is a forked branch of hazel, suspended by two prongs between the balls of the thumbs. The inclination of the rod indicates the presence of water-springs, precious metals, and anything else that simpletons will pay for. This is a very ancient belief which pertains to the yet lingering practice of witchcraft. There are many people in this country who believe in the efficacy of this method for determining the whereabouts of water-springs, etc.; and in Continental Europe, even amongst the educated classes, there are many persons who would not think for a moment of sinking a well without first consulting an expert diviner, and, indeed, many of these diviners may be found among the ecclesiastics, who make it a source of income. The action of the "Witch-Hazel" in the hands of some people has never yet been satisfactorily explained, but is supposed to be the result of unconscious effort on the part of the holder. It may be safely stated, however, that the presence of water or precious metals has nothing to do with the movements of the twig.

28. Monograms, J. H. P., Brooklyn, N. Y.—I enclose three monograms of the initials J. H. P., T. W. T., and S. N. B., and hope they will suit your querists. If these are satisfactory, I shall be pleased to send others for publication, if your subscribers will make known their wants in this line. I am very much pleased with the Young Scientist, and expect to send you a big club from this city before long, as I am going to make an effort to capture that gold watch you offer as a premium for the largest number of subscriptions sent to you during the present year.—X., Cincinnati, O.

Note.—We shall be pleased to award the watch to friend X., and hope he will have the success he expects and deserves in obtaining names for the Young Scientist. We hope all of our young readers will take an interest in this extra premium scheme. We invite all our readers—boys and girls—to carefully read the second page of front cover, and see the fine chances we are offering them for obtaining something useful, and at the same time making money on the commissions offered. We shall be pleased to give any further information on this matter to such of our readers as may require it, if they will communicate with us on the subject.

29. Nina, Toledo, O.—If Nina will adhere to the following instructions, she will obtain excellent results:

Cut from the lithograph or engraving you wish to transfer, all the margin, then lay it in a pan of tepid water until it sinks, after which remove it and place it between dry papers to dry. This done, clean a square or oval piece of glass and wipe dry; cover it with Damar varnish, spreading it on evenly with a flat varnish brush. This done, lay away until nearly dry, so it will not stick to your fingers when touched, but snap when your finger is removed; then lay your picture upon any smooth surface, with the right side up, and hold your varnished glass on it with the varnished side down in the position you want the picture on the glass. Lay the glass down carefully; this will unite the glass and the face of the picture.

Next take a piece of dry paper and lay on the back of the picture. Where air bubbles or blisters are seen, press them lightly with your fingers from the centre of the picture outwards. Do not let a single one remain, and always keep a dry paper between your fingers and the picture, or you will roll up the paper and spoil the picture.

When the blisters are all removed, set away until the varnish is dry, which will take about twelve hours. Wet the paper with water, and rub it with your fingers until all the paper is removed but a light film; then set away for twenty minutes; varnish again with Damar varnish, and that will make it clear and transparent. When the picture is well dried, paint it on the wrong side, following the boundary and covering the surface and form of every figure and portion of your design as designated by your picture, using artists' colors and brushes. Lay your colors on heavily; mix them with Damar varnish before using. No shading is required, as that is given by the engraving. In painting the figure of a person, first paint the eyes and hair, let them dry; then the flesh color; then the draperies and backgrounds. Paint very carefully, and do not let the colors run into each other. In painting the eyes, first paint the white of the eye with silver white; for the pupil, ivory black; for blue eyes, Prussian blue and silver white mixed; for hazel, yellow ochre, Vandyke brown and a little raw sienna mixed. For flesh tints mix Naples yellow, scarlet lake, and silver white to the desired tint.

S N B.

T W T.

J H P.

Colors for drapery are: Buff, Naples yellow; orange, chrome yellow and a little scarlet lake mixed; white, silver white; blue, white and Persian blue mixed; green, chrome yellow and Persian blue mixed; purple, scarlet lake and Prussian blue.

For jewelry use yellow ochre; for silver and pearls, silver white.

For trunks and branches of trees, Vandyke brown, raw sienna and silver white mixed; foliage, mix chrome yellow and Prussian blue, and vary with the browns; for earth, raw sienna and white mixed; rocks, Vandyke brown, white and raw sienna mixed; water, Prussian blue, white and a small quantity of green; distant hills, make it a little deeper blue; the sky, Prussian blue and white, applied as follows: First paint the portion next to the tops of the hills, trees, etc., with entire white; then mix a very small quantity of Prussian blue as you go upwards on the picture. If you wish a warm appearance on the horizon, mix a small quantity of scarlet lake to give it a red tinge. Colors generally used for backgrounds are Vandyke brown, raw sienna and white, varied light or dark with more or less white mixed with it; or backgrounds can be painted after the rest is done by mixing all the different sorts together that are left.

If you make a false stroke you can remove the paint with a rag dipped in turpentine. The brushes may also be cleaned in the same way.

To make a transparency for hanging in the window after you have made the picture transparent according to the directions given above, place a second glass on the back, bind the edges with a thin paper, and when dry paste over this strips of bookbinders' cloth. When you put this on, paste along the sides a piece of narrow ribbon or tape, allowing it to project out over the two upper corners in the form of two short loops through which a cord can be passed to hang it up by. Pictures for transparencies cannot be painted, but a colored engraving can be used.—A. B.

30. H.,N. Y., sends the following: "Is the answer to R. G. (2), February number, concerning 'The Swiss Family Robinson,' wherein it was stated that the book was written by J. H. Kampe, correct? Now, in a French edition in my possession the author is said to be John Rudolph Wyss, born at Berne, March 13, 1781; died at Berne, March 31, 1830. His father had planned the work, but John Rudolph Wyss wrote it. Who is correct, S. K. or I?"

NOTE.—Formerly there was some doubt as to the authorship of this fascinating work, and it was ascribed to a number of sources; it has been ascertained latterly, however, beyond doubt, that the book is the work of Kampe, Humboldt's tutor. Miss Yonge, who is an excellent authority on the subject, says: "No one but a German could have thought it practicable to land a whole family in a row of washing-tubs nailed together between planks, on a desert island." The work was doubtless suggested by De Foe's "Robinson Crusoe." The two monograms you send us in reply to J. H. P. and T. W. T. (query 23), arrived too late to get the cuts made early enough for the present issue. They will appear in our April number.

Queries.

31. J. S., Somerville, N. J.—If you drop a postal-card to Peck & Snyder, 126–130 Nassau St., New York City, they will send you a catalogue containing all the information you ask for concerning ice and roller-skates.

32. MONOGRAMS.—G. F. M., A. B., and G. S., ask for monograms of those initials, and request some of our competent readers to forward designs to this office for publication.

33. INLAID MONOGRAM.—E. B. desires a monogram of his initials for inlay, to be cut with an ordinary Challenge scroll-saw. The work is intended for the top of a glove-box, and the design would be preferred on an oblong or oval background. "Please state, also, the kinds of wood that would be the most suitable for designs sent."—E. B., Atlanta, Ga.

34. OVERLAY DESIGNS.—If not asking too much of you, I should feel under obligations if you would publish a few designs for overlay fret-work, suitable for the panels of a wardrobe or chiffoniere. Perhaps some brother subscriber would kindly contribute such designs as I require.—ROBERT H., Erie, Pa.

35. KATY V. desires to know (1st) What is meant by the language of colors? (2d) When did type-writing machines first come into vogue, and what they are like?—Louisville, Ky.

36. PAINTING ON SATIN.—Will you kindly inform me how this kind of work is done, and name the materials employed?—A COUNTRY GIRL.

37. REVENUE MARINE SERVICE.—What requirements and qualifications are necessary to obtain an appointment in this service?—HARRY S., Phila, Pa.

38. M. H., Homestead, Ia.—Will you please inform me where I can purchase the shells for ornamental shell-work quoted in your market reports?

NOTE.—Several inquiries of this kind have reached us of late, and we have been obliged to give the answers by mail. Hereafter we hope to be able to give our readers much of this sort of information through our advertising columns. It will always give us pleasure to reply by mail or otherwise to all inquiries of this kind, and we hope our readers will note this fact and write us freely for any information we may be able to afford.

39. J. A., Colela, Ia.—Will some reader inform me how many bones there are in the human body? There appears to be a difference on the subject among reputed authorities. One says there are 204, another 246, and still another 260, and in a recent newspaper article I notice the number is placed at 202. Now which is right, or are any of the foregoing figures right?

40. QUINER.—As myself and others are interested in the art of pottery, a few practical hints on glazing, preparing clay, etc., in the YOUNG SCIENTIST, would be duly appreciated.

Market Report.

Retail Prices.

IMPORTED CAGE BIRDS.

Canaries, *Belgian*, per pair	$6.00 to 15.00
" *French*, each	6.00 to 15.00
" *German, Hartz Mts.*, each	2.50 to 10.00
Gold Finches, each	1.50
Gold Finch (mules), each	2.50 to 5.00
Bull Finches, each	2.50
Bull Finches (tuned), each	10.00 to 40.00
African Finches, per pair	2.50 to 5.00
Chaf Finches, each	1.50
Linnets, each	1.50 to 2.00
Linnets (mules), each	2.50 to 5.00
Green Linnets, each	1.50
Java Sparrows (blue), each	1.50
Java Sparrows (white), per pair	4.00 to 6.00
English Sparrows, per pair	1.00

Siskins, each	$1.00
Gray Cardinal, each	4.00 to 5.00
Nightingales, each	8.00 to 25.00
Japanese Nightingales, each	5.00 to 10.00
Thrushes, each	5.00
Skylarks, each	5.00
Troopials, each	7.00 to 12.00
European blackbirds, each	5 00
Black-caps, each	4.00
Starlings, each	4.00 to 6.00
Ring Doves, each	2.50 to 3.00

AMERICAN CAGE BIRDS.

Canaries, each	2.50
Mocking Birds, females, each	1.00
" " singers	12.00
Robins	2.50 to 5.00
Blue Birds ("Blue Robins") each	1.50 to 2.00
Indigo Birds, each	1.00
Nonpariel, each	1.50 to 2.00
Virginia Cardinal, each	3.00
Bobolinks, each	1.50 to 2.00
Yellow Birds, each	1.50 to 2.00

QUADRUPEDS.

Terriers, *black and tan*, each	5.00 to 30.00
Terriers, *Scotch and Skye*, each	5.00 to 30.00
Newfoundland Pups, each	10.00 to 15.00
Pomeranian or Spitz "	5.00 to 15.00
Greyhounds, *English*, "	10.00 to 25.00
Greyounds, *Italian*, "	10.00 to 30.00
Guinea-Pigs, *common*, per pair	1.50
" " " " large	1.50 to 3.00
Guinea-Pigs, *all white*, "	2.00 to 4.00
Squirrels, *gray*, "	5.00
Squirrels, *all white* "	15.00 to 25.00
Squirrels, *flying* "	3.00 to 4.00
Squirrels, *small red* "	2.00
Rabbits, *common*, per pair	1.00 to 2.50
Rabbits, *fancy breed*, according to age and purity of breed, per pair	3.00 to 15.00
Ferrets, *English*, "	15.00
Raccoons, each	4.00 to 5.00
Cats, *Maltese* (males), each	5.00
" " (females), each	3.00
Cats, *Albinos, pink or blue eyes*, each	3.00 to 5.00
Rats, *white China, pink eyes*, per pair	1.50
Rats, *piebald*, per pair	1.50
Mice, *white, pink eyes*, per pair	0.50
Mice, *piebald*, per pair	0.50

Prices Paid for Pet Stock by Dealers.

At this season of the year the prices paid for pet stock of all kinds are very low; this is on account of the demand for said stock falling off greatly after the holidays. Rabbits (common) are now ranging from 50 to 75 cents per pair, according to age and color.

Guinea-Pigs, per pair	$0.40 to 0 75
Squirrels, *gray*, each	0.50 to 1.00
Squirrels, *flying*, per pair	0.25 to 0.50
White mice, per pair	0.15 to 0 20

MARINE AQUARIA STOCK.

Fringed Sea Anemone, Medium-sized specimens	1.50
White-Armed Anemone	0.50
Small Orange "	0.10
Buccinum Snails, per dozen	0.25
Small Crabs, each	0.25
Silver Shrimp, each	0.10
Small Hermit Crabs, each	0.15
Small Spider " "	0.25
Barnacles, each	0.15
Lebia Fish, each	0.25
Killie " "	0 10
Eels, "	0.10
Serpulæ, per mass	0.75
Edible Mussels, per mass	0.25

ALGÆ "SEA-WEEDS."

Ulva, per mass	0.25 to 0.50
Solaria, "	0.25 to 0.50

FRESH WATER AQUARIA STOCK.

FRESH-WATER STOCK.

Stickle Backs, Nest-building, per pair........ 0.30

Plants, per bunch	0.15	Small Turtles, per pair.	0.25
Shells, per quart	0.50	Snails, per dozen	0.20
Small Dip-Nets	0.50	Frogs, each	0.25
Aquaria Cement 1 lb. box	0.30	Fresh-Water Mussels	0.10

Valisneria Spiralis, per bunch	0.25	For the Microscope and Fresh Water Aquarium.
Nitella-Flexilis, "	0.25	
Anacharis, "	0 25	

Small Rock-Fish, Sun-Fish, Dace, Cat-Fish, Tadpoles, Eels, Lizards, each 0.10

Gold-Fish		These are all varieties of the golden carp or gold-fish.
Pearl-Fish		
Silver-Fish		
Japanese King-gio	2.00	

Prices Paid by Dealers.

At this season of the year all stock for aquaria brings a high price.

Aquarium fish (*now scarce*) per hundred	1.50 to 2.00
Gold Fish (*now scarce*) per hundred	8.00 to 10.00
Aquarium Plants (*now scarce*) per hundred bunches	5.00

SHELLS.

Collections of small "cabinet" shells for schools, private cabinets, range from $5.00 to $50 00.

Mother-of-pearl shells, for painting, 75 cts. to $1.50.

Single specimens of cabinet shells range from 25 cts. each to $3.00.

Masses of corals, 50 cts. to $3.00.

Green snail and cowry, with the Lord's Prayer engraved on them, 50 cts. to $2.50 each.

Conch shells, for mantels or hearthstone ornaments: West India Conch, 25 cts.; East India Yellow Helmet, $1.00 to $2.50; Bahama Black Helmet, 50 cts. to $1 50; Bahama Hatchet Helmet, 50 cts. to $1.25. These shells are also for cameo engraving. Zanzibar Cameo, 25 cts. to $1.00.

Ground and polished shells: New Zealand Green Ear, 50 to 75 cts.; New Zealand White Ear, 50 to 75 cts.; Japan Black Ear, 50 cts. to $1.00; California Red Ear, 75 cts. to $1.25.

Fine shells for fancy work, according to colors and variety, per quart, $1.00 and up.

Fancy Wood for Scroll Sawing.

The prices given for the various woods used in this work are for the best of qualities of seasoned material, planed on both sides, ready for immediate use. They can be furnished in quantities to suit purchasers. Prices are by the square foot, and vary according to thickness of material.

For all information on this subject, as to reliable dealers, etc., etc., send postal card to YOUNG SCIENTIST. When desired, the goods can be sent through this office, but in all cases remittances must accompany the order.

EXCHANGES.

Only those who are *yearly* subscribers, and whose names are entered on our books have the privilege of inserting exchanges.

Exchanges must be on separate slips of paper or postal cards. If mixed with business matter in letters or cards they are filed away and never reach the printer.

Exchanges must not exceed thirty words.

Buying and selling belong to the advertising department.

We reserve the right to omit the exchange column, when we have not room for it, and the amount of space at our disposal will regulate the number of insertions given to each *exchange*, the preference being always given to those who have not previously used our columns.

Silver watch, key-winder and Home Works, for good microscope or offers. Wm. Hodgson, 128 Mangin St., New York City.

A small collection of coleoptera, comprising 100 species and 300 specimens, all correctly named, in exchange for bird-skins, insects, books, or eggs. Emil Laurent, 621 Marshall St., Phila., Pa.

A small magic lantern, Ruby pattern, with twelve slides, for a good book on Entomology, with illustrations. Willie R. Hotchkiss, Morrisdale Mines, Clearfield Co., Pa.

Wanted, Thompson's "Witchery of Archery." Must be in good condition. Write before you send. J. Anthony, Jr., Coleta, Whiteside Co., Illinois.

A telescope worth $3.50, for a self-inking printing-press and outfit; chase not less than 2½ by 3½ in. Eddie Judd, 260 Connecticut St., Buffalo, N.Y.

To exchange for offers: $20 scroll-saw, Seneca Falls make, $4 Bailey circular plane, set of Auburn metallic planes, brass-bound four-foot rule, fourfold, Traut's patent combined plow, dado, etc., cost $7. F. A. Rappleye, P.O. Box 12, Farmer Village, Seneca Co., N.Y.

Bee Hive wanted; one of the old-fashioned straw "skeps"; say what you would like in exchange. Apis, care of Young Scientist, 49 Maiden Lane, N. Y.

A first-class type writer, in excellent condition, cost $125.00, to exchange for good microscope, telescope, or valuable scientific books; send full particulars. A. B., Box 114, Lewiston, Maine.

A $30 stencil outfit (Spencer's) for a self-inking printing press in good condition, chase about 6 x 9; rich ores and minerals of Idaho for scientific and instructive books, printing press, type, etc. J. P. Clough, Junction, Lemhi Co., Idaho.

Wanted pyrites of iron from Colorado gold mines in exchange for sea shells and other gems; send list of what you have to exchange. S. Ferguson, Eureka Springs, Arkansas.

Scientific specimens of various kinds for same. Geo. E. Frazier, Caldwell, Ohio.

A banjo in good condition, two pairs of rosewood bones, three splendid games, and a fine set of drawing instruments, for a good cornet, viola, violincello or double bass. L. B. Hill, Kalamazoo, Mich.

A good telescope, also foot-lathe and saw combined, each worth $10.00, for shells, fossils or relics. Independent, Conneautville, Crawford Co., Pa.

Birds' eggs to exchange for others; send list of what you have to exchange. Emil Laurent, 621 Marshall St., Philadelphia, Pa.

Lester W. Mann, Randolph, Mass., Box 162, has Demas scroll saw, lathe and tools, emery wheel; $20 worth patterns; Smithograph; large harmonica, cost $1.75; novelties in seeds; for large self-inking press or offers.

10 volumes Chambers' Encyclopædia, American Book Exchange edition (cloth); Bonanza printing press, chase 3 x 5, card type, ink roller; spyglass, power 10 times; for French triplet, 1-5 in., or offers. H. P. Nichols, P. O. Address, Bridgeport, Conn.

Twelve or fifteen volumes of the American Agriculturist to exchange for scientific books or offers. W. H. Osborne, Chardon, Ohio.

J. D. Rice, P. O. Box 473, Trenton, N. J., would be pleased to correspond with mineralogists for the purpose of exchanging specimens and ideas.

To exchange, my collection of nearly half a thousand rare postage stamps with catalogue, for second-hand Flobert rifle; must be in good condition. H. E. Whitman, Station M, New York.

I have a large assortment of foreign stamps to exchange, also Confederate money. Collectors send sheet and I will return it with mine. Box No. 2, Coeymans, N. Y.

Electric bell engine, cost $15; pair of analytical scales, cost $10; pair of Bell Telephones to exchange for a printing press, watch or offers. Geo. N. Bigelow, Box 754, Palmyra, N. Y.

Any person wishing to trade bird's eggs may apply to me and I will send them my list of bird's eggs. I have only a few at present, but am receiving a number every month. A. G. G., Box 26, Summit, New Jersey.

Minerals of Idaho for Standard Works on the Horse—Wallace's Registers and turf journals. Wanted, also other useful books, bound and in good condition. Many varieties named in my list. J. P. Clough, Junction Lemhi Co., Idaho.

To exchange for offers first four (fifth when completed) bound volumes of YOUNG SCIENTIST. J. N. Brooks, P.O. 1468, N. Y. City.

Wanted engraver's tools with book of instructions, for a Victor Press, with cabinet, 2 type cases, type, ink roller and furniture complete; perfectly new. L. Warren, 72 Cumberland St., Brooklyn, N. Y.

A Fletcher Foot-Blower, cost $5, as good as new; will exchange for a Cushman, 2 in. or up scroll chuck, or other make; will give a satisfactory trade on the difference in price, if any. Louis Lutz, St. Clair Street, Toledo, O.

I have a lot of "Galaxy" (magazines) which I would like to exchange for an air rifle in good condition, a collection of birds' eggs, or offers. W. B. Greenleaf, 480 La Salle Ave., Chicago, Ill.

I have a Mechanical Telegraph with book of instructions, books, etc., which I wish to exchange for good microscopical objects, mounted on 3 x 1 slips. Address, with list, J. H. Frey, Millersburg, Ohio.

To exchange, "How to Use Microscope," Wells' "Natural Philosophy," and many other books, chemical apparatus, etc., for good photographic camera, and lenses. W. H. Weed, 254 Putnam Ave., Brooklyn, N. Y.

Wanted "Quimby's New Bee Keeping," for "Our Own Birds of the United States," by W. S. Baily; new. Joseph Anthony, Jr., Colota, Whiteside Co., Ill.

Wanted a good book in anatomy, in exchange for a book on chemistry, or for story books. A. G. G., Box 26, Summit, New Jersey.

A German-silver trimmed, patent lined, cocoa flute, cost $4, in good order, for good spy-glass, photo-material, or offers. Ewing McLean, Greencastle, Ind.

I have some fossil shells from the west bank of the Mississippi, to exchange for Indian relics. A. W. S., 187 E. 71st St., N. Y.

I have a magic lantern, Ruby pattern, nearly new, and 5 views; also "Our First Century," bound in leather, cost $7; state what is wanted in exchange. I. N. Spencer, Box. 217, So. Manchester, Conn.

First-class telegraph instrument and attachments, and "Wood's Botany," for bound volumes of periodicals, books, or offers. H. P. Albert, Anderson, Iowa.

Wanted a book on treatment and care of canary, also breeding of same; will give in exchange book named "Market Garden, Flower Garden and Bees," or 40 "Scientific Americans" or "Seaside Libraries;" want also old books. M. J. Mulvihill, Norwalk, Conn.

Coins, minerals, stamps, books, type, fishing tackle (very complete) and fish pole, bronze inkstand, etc., for coins, medals, stamps, war envelopes, old newspapers, and Continental, Colonial and Confederate currency. F. F. Fletcher, 103 Main St., St. Johnsburg, Vt.

Blow-pipe set (cost $10), large illustrated family Bible (cost $7.50), for Wood's Botany, Dana's Geology, or printing press and type. H. W. Noble, Box 134, South Dansville, N. Y.

I have a number of birds' eggs I should like to trade for other birds' eggs; send for list of trading eggs. A. G. G., Box 26, Summit, New Jersey.

HOME ARTS.

VOL. VI. NEW YORK, APRIL, 1883. No. 4.

Something About Saws.—III.

BY "OUR NED."

HAVING fairly discussed the methods of filing hand-ripping and cross-cutting saws from an amateur's standpoint, I will now take up the smaller saws. The back-saw, Fig. 1, may be of various lengths and sizes, but in some one of its forms it is indispensible to the amateur wood-worker. The tenon saw, which is about twelve inches in length, is, perhaps, the most useful for the amateur who can only afford one back-saw, but where two saws of this kind can be obtained, one should be fourteen or sixteen inches long, and the other a thin-bladed, dove-tail saw, about eight inches long in the blade and having about eighteen or twenty teeth to the inch. This latter saw should be kept for cutting the shoulders or small tenons, dove-tail work, and making fine joints. As the blade is very thin, it does not require much "set," but care must be taken not to force it through the wood if there is a tendency towards sticking, as a twist or false movement of the hand may spoil the saw, as the blades are very easily buckled, or "kinked."

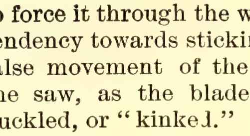

Fig. 1.

Fig. 2 shows the style of teeth required in saws of this kind. The backs of the teeth are left square and the cutting edges filed more or less beveling, according to the hardness of the materials to be cut. If the wood is of a soft kind, such as pine, cedar, poplar or butternut, a little more bevel than is shown in the engraving may be used, but if the wood is hard, such as oak, ash, hickory, walnut or mahogany, then less bevel will answer; but for general purposes, that is, where the saw is intended for cutting all kinds of wood,

soft, medium and hard, the shape of teeth should be as near to those shown as possible.

The larger back-saws are often used for sawing tenons, and therefore have to perform the services of a rip-saw. In hardwood work the ordinary back-saw tooth

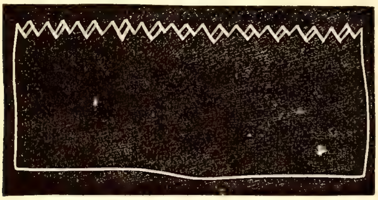

Fig. 2.

will rip pretty fairly, but it does not work so satisfactorily in soft wood; still, in amateur work it will be found better to employ the back-saw for ripping tenons than a rip-saw, as the inexperienced workman will find it so much easier to follow the lines with the former, and, though he may not do the work so rapidly, it will be better done.

If the blade of a back-saw should get slightly "buckled" or crooked, it may be straightened—in a great many cases—by tapping the back gently with a hammer, but care must be taken not to overdo it. A little practice in this matter will soon teach the operator how to obtain the best results.

In the common hand-saw it is necessary that the line of teeth should be continuous or straight to insure the efficient working of the instrument, and this becomes more necessary in a back-saw, for if the teeth are not in line or straight, both on their line of points and on their sides, the saw will make terrible work on fine shoulders, dove-tails, or mitres, the raggedness and tearing of the fibres showing more plainly on fine work than on work done with the coarser saws. Another thing: when the saw is used in a mitre-box, if the teeth are not jointed on the sides with an oil-stone, the projecting points will soon destroy the truth of the mitre cuts, and render it almost impossible to cut a nice clean mitre joint, thus causing a great deal of unnecessary trouble in fitting the joint with a block-plane.

Joints cut with these saws should be good without any repairing; if they do not fit, something is wrong—the saw is out of order or the workmanship is clumsy and careless. In cutting shoulders for tenons, it is always better, when practicable, to rip down the tenons first, leaving the shoulders uncut until the last thing. This saves the shoulders from getting bruised or damaged in any way by falls or with having other stuff thrown against them. A little oil or grease should occasionally be applied to the blades and backs of these saws, to keep them from rusting or getting covered with a sticky film, which is sure to occur if they are only used once in awhile, and then used in pine. Of course, very little oil or grease must be used on the blade, for too much would scrape off in sawing joints and spoil the stuff for gluing, besides discoloring the joint and unfitting that part for taking varnish or polish.

If my amateur friends will again read the papers in the February and March numbers of the YOUNG SCIENTIST on this subject, and connect them with the present paper, I think they will have no difficulty in thoroughly understanding the methods necessary for filing and caring for the three classes of hand-saws discussed, namely—cross-cutting saws, ripping-saws, and back-saws for general purposes; and feeling that this is the case, I leave them now, and will in my next take up a few of the other sorts of saws that amateurs are sometimes obliged to use.

Cheap, Swift and Safe Canoes.

BY W. L. D. O'GRADY.

A WISE man may pick up some things worth knowing almost anywhere. Many of our most wonderful inventions sprang from very humble beginnings. Perhaps I can give a hint or two picked up in India which may add to the enjoyments of the readers of the YOUNG SCIENTIST.

Many boys love sailing, rowing and paddling, all of them manly and healthful exercises, yet cannot afford boats

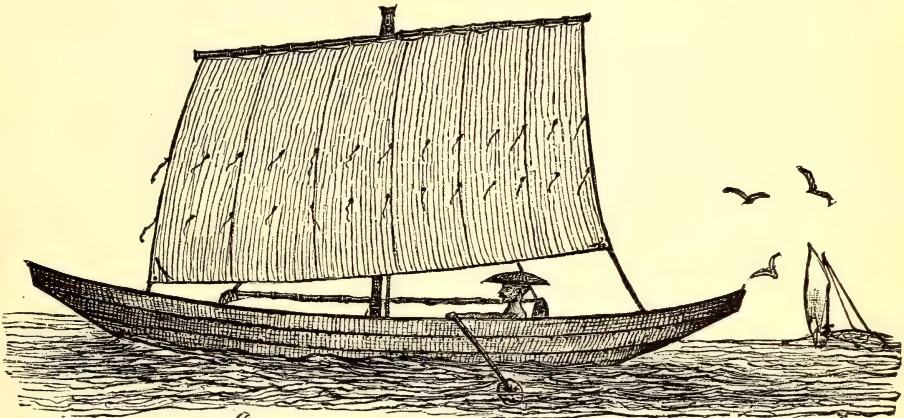
of their own, and do not like to trespass too often on the good-nature of their friends. Others are kept from the water by their parents or guardians, because boating is often dangerous—always so with ignorance, carelessness or unsuitable vessels.

The boat here illustrated (Fig. 1) is of very rude construction, but swift and safe. It can be copied and improved upon as to its appearance very cheaply with the materials at our command. It is not very roomy, but ships less water in the heaviest seaway than a craft of any other model. It is so buoyant that it is impossible to sink it, and, so long as it holds together, cannot be upset. It is easily managed, and will carry thirty grown-up people at a pinch, well squeezed together. It looks something like a spider, but were it not that it takes up so much room on a ship's deck, and when out of water is so practically no better, if as good. (These double canoes, by the way, have no sort of resemblance to the genuine Madras catamaran [or "tied tree" in the Tamil

"Katta" *tied.* "Maram" *tree.*

language], which is made of three logs tied together, the longest in the middle, turned up at the fore-end, with a crew of one, dressed in an extinguisher-shaped cap, in which he carries letters to ships across the terrible surf of the Coromandel coast and any little trifle of tobacco or betel which he wants to keep dry, and not much besides. His paddle is always a piece of broken plank.)

The materials of this Cingalese yacht are wood, bamboo, coir yarn and coir



Cingalese Canoe

Fig. 1.

awkward to handle, could not be equalled as a lifeboat. It is the favorite fishing-boat of Ceylon, the Malabar or western coast of India, the Maldive and Laccadive Islands. It is not unlike, in many respects, the famous flying *phahus* of the Ladrone Islands, first described by Commodore Anson, the circumnavigator, and the latest of our very expensive so-called "catamarans" are indebted to these for their most important feature, and are rope, made from the fibrous husk of cocoanuts. There is not a nail about it. We should probably use cedar for the hull and outrigger, ash for the outrigger poles, and nails instead of coir yarn, and also a little paint or varnish. For the rigging (Fig. 2), coir rope would do as well as any substitute, and can easily be got here. Our sail would be of cotton, nicely made, instead of matting or patched gunnybags sewn together.

The Cingalese yachtsman wears a bamboo ring on his head, which supports a small palmleaf umbrella. We should prefer a hat or cap, and also some more clothing than he usually gets along with.

The keel is a log, pointed at both ends, somewhere about twenty feet long. A trench is cut in this along all its length, except at the ends, to receive the planking of the sides, which are built up, or rather tied together, three or four feet high, with a good shear or rise at stem or stern (which are both alike and sharp); but while one side is built straight, or nearly so, the other has the lines of an

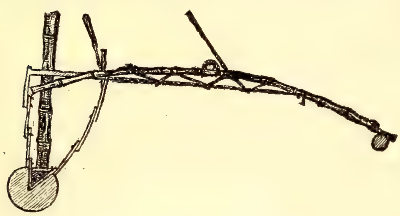


Fig. 2.

ordinary boat, leaving an opening in the middle of hardly more than two feet. From the latter or weather side is extended, at a distance of eight to twelve feet, by bamboo poles, curved so as to keep them out of the water as much as possible, a pole three or four inches in diameter and about ten feet long, pointed at both ends, the whole being loosely but securely fastened together with a multitude of coir yarn and rope lashings, guys and stays. The flat side keeps the boat from drifting to leeward, and the weight of the outrigger keeps it from being capsized, while the displacement is so small and the model is so sharp that it is very speedy. The mast is of bamboo, in the middle, and the single halliard, fastened amidships at the weather gunwale, often does duty as a single shroud. The square sail has two ropes at the lower corners, one fast as a tack and the other flowing as a sheet, and is usually kept on the flat side of the boat, tacking being dispensed with in beating to windward, letting go the one rope used as a tack and hauling in the one used as a sheet, answering the same purpose. Reefing is never thought of in any sort of weather much short of a cyclone, as, if the pressure of wind is

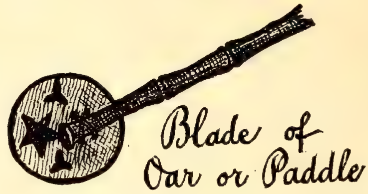

Fig. 3.

heavy, scrambling out on the outrigger gives a tremendous leverage to counteract it. The boat is steered with a paddle or oar (Fig. 3) from either end. The blades are circular, about the size of a dinner-

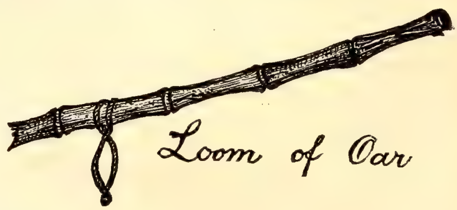

Fig. 4.

plate, and are often adorned with paint. They are fastened to bamboos (Fig. 4) by coir yarn, passed through holes drilled in them. The paddles have a cross handle, (Fig. 5), while the oars, which are rarely over eight feet long, are supplied with a loop of coir rope, which is passed over a single thowl pin (Fig. 6), much resembling that used on the gondolas of Venice, which is usually shipped and unshipped with the oar. They are simply let go whenever the oarsman wants to pull in a fish or fill his pipe without any danger of being lost, and are pulled noise-

Fig. 5.

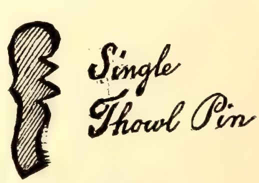

Fig. 6.

lessly, which is sometimes an advantage.

A good imitation of this Asiatic craft could be made, costing not more than twenty dollars anywhere in the United States, and in many places would cost much less. All boys, and girls, too, should be able to swim. Those who can, if reasonably careful, might be trusted by the most timid of relatives in such a canoe, and they would find plenty of fun in holding out a towrope in any weather to most of the high-priced yachts they may fall in with.

Sea Anemones.—II.

BY A. W. ROBERTS.

SOME years ago, becoming greatly interested in the 'dandy' or decorating spider crabs, which are given to ornamenting themselves with bright colored bits of sea-weeds, etc., the idea suggested itself to me to cut up into reasonably small pieces a purple Bermuda anemone, and to slice off from the expanded bases of the brightest colored of the fringed anemones, enough material to supply a small decorating spider-crab that had been hunting in vain for sea-weeds with which to adorn himself. Placing the crab in a sand bottom tank, I confined him in one corner by means of a pane of window glass. In less than an hour's time, after the hashed up anemones had been placed in his compartment, he was hard at work deliberately (and with that peculiarly solemn and grave expression, that all the spider-crabs possess) fastening piece after piece of anemone to his upper shell. As he grasped each piece in his claw he then conveyed it to his mouth where he covered it with a marine glue peculiar to spider-crabs; then slowly but surely he raised it to his back and with a slight downward pressure of the claw he placed it in position. And, so he continued till his entire back was covered with particles of anemones. In the course of three to four weeks he was carrying about with him a vigorous colony of young anemones—and wasn't he a beauty!

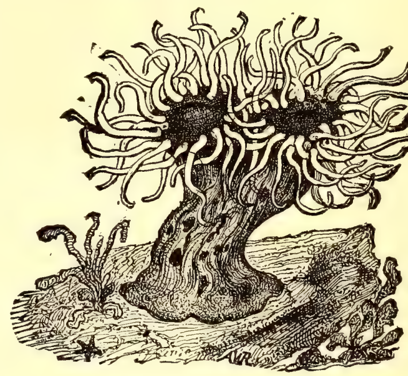

Fig. 1.—Showing anemone with double disk, and food passing into stomach.

On another occasion having an anemone that was very uniquely mottled with brown and pure white, and of which I was very anxious to obtain more specimens of the same kind, I determined to resort to a vigorous system of division from the base of said anemone, by means of a razor, and thus multiply this variety

Fig. 2.—Double-bodied anemone, showing the action of the lasso cells, which are invisible, except under the microscope.

almost to an unlimited number of specimens. In the first place I took the precaution to feed the parent anemone liberally with the fattest of silver shrimps, for

which he had a great liking, so as to always have him in the most robust health. Every morning I applied the keen razor to the extreme outer edge of his base, and so secured from four to five fragments. Did it pain him? No; not in the least. Did he close up suddenly? No. Did he stop taking the gentle shrimp? No. He just went right on attending to his own private, every-day affairs. And as fast as his base grew out again, I relieved him of it; and thus it came to pass that in course of time I had gathered about him a proud family of anemone youngsters just like their papa and mamma, for anemones are both in one.

Fig. 3 represents a section of anemone, showing the inner tube or stomach, and its division by numerous radiating partitions.

To again illustrate the wonderful tenacity of life that these animals possess, I will relate a remarkable example of endurance. When collecting at Cape Cod, Mass., I left by accident some forty or fifty small-sized anemones on one of the long docks. After the expiration of several days, I had occasion to visit this same dock; the anemones were still there, but were very much dried up and parched, so much so that they presented hardly more than what appeared to be a circular stain on the stringpiece of the dock. Still, it occurred to me to peel them off carefully and place them in water, just to ascertain if they still possessed any vitality. Having done so, I forgot all about them for a week's time, and, upon examining them, was greatly surprised to find that fully one-half of the number had survived the ordeal through which they had passed. With all varieties of anemones many interesting freaks of form occur, as for instance, I have had anemones with double and treble disks (Fig. 1), and others with two bodies (Fig. 2) starting from a common base.

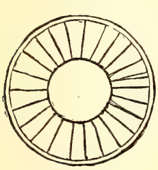

Fig. 3.

In collecting the smaller varieties of anemones great care must be taken, when detaching them from the timbers or rocks on which they have fastened, not to injure or tear through the base, so that any part of the outer wall of the anemone becomes lacerated, or otherwise they will die. The best method is to slowly insert the nail of the thumb under the outer portion or rim of the foot of the anemone, and then, by a persistent and slow pressure, peel the foot away from its attachment.

Fig. 4 shows the "scraper," mentioned in the February issue of the YOUNG SCIENTIST, intended for capturing anemones.

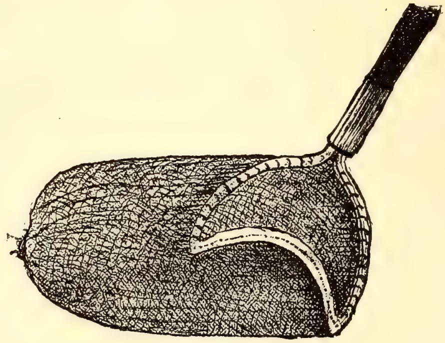

Fig. 4.

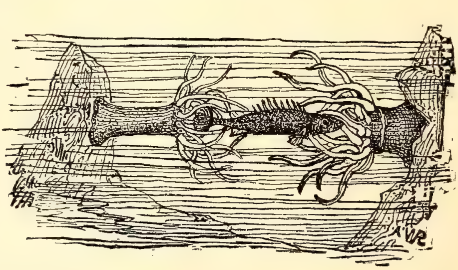
It is well for our younger readers to bear in mind that anemones can be sent a great distance by express when packed in what is known as "dry packing." By dry packing is meant placing the anemones between layers of damp rock-weed *(Fucus nodosus)*, from one to two inches in depth. The box in which the anemones are packed should be thoroughly soaked both inside and outside for a few days. This will cause all the joints to swell, and thus make the box air-tight. Some very careful collectors place an inner lining in the box consisting of oiled or rubber-coated paper, which can be obtained of all florists, at little cost.

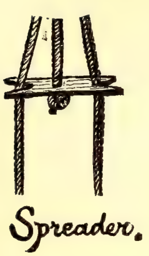


The Mud-Bows of India.

BY W. L. D. O'GRADY.

ARCHERY is a pleasant pastime, but if carried out in all the completeness considered necessary nowadays, is a very expensive one. Much fun can be obtained very cheaply by using a bow and dried balls of clay, instead of arrows. The mud-bow (as it is called) is popular in India. It has two strings, with a patch of cloth connecting them in the middle. With

Fig. 1.



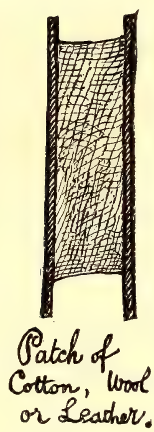


Fig. 3. Fig. 2.

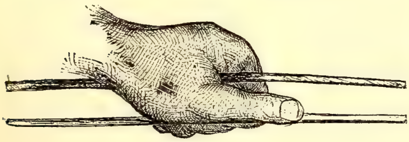

Fig. 4.

Fig. 1. Mud-bow with two strings.

Fig. 2. A patch in the middle, between them.

Fig. 3. Spreaders near each end, to keep the patch from "buckling" or wrinkling up.

Fig. 4. Position of bow when drawn, slightly turned, so as to let the ball pass the thumb. The thumb-nail should be exactly opposite to the centre of the patch.

practice great accuracy may be attained and the missiles can be propelled with force enough to kill small game as far off as a shotgun would reach. Beginners have to be careful, as otherwise they are apt to strike their left thumbs with considerable severity. Idle young officers in India often exercise their skill on peddlers and tramps, and drive them off howling dismally; but this is not a commendable sport. They also use crows as targets, but there is no record of any crow ever having been hit. The Indian crows are wary birds.

A very effective bow could be made here at the cost of ten cents. In India, the regular price of the best manufactured article is half a rupee, about eleven cents. It is not quite as handsome as a lancewood or yew bow, with all its appurtenances. It may be noted that clay balls are cheaper than arrows, and will not stick in people's eyes. They will, however, break glass and kill chickens, if misdirected. They are held between the finger and thumb, at the forepart of the patch, between the strings, and discharged when the bow is bent sufficiently, just like an arrow, on the right side, unless with a left-handed person, the bow being twisted just far enough to the left to allow the ball to pass it. If twisted too far, the ball will go very wide of the mark. With patience and practice the knack is easily learnt. A convenient size for the ball is that of an ordinary marble.

Overlay Work.

ONE of our correspondents asks through our query department for designs of overlay work for small door panels. We herewith publish six different designs intended for the purpose asked.

No. 1 is a very plain pattern, but effective withal, and if cut in light-colored wood—ash, maple or satinwood—and planted in a dark background of mahogany, walnut or teak, it would be very pleasing. No. 2 is a little more elaborate, but would give good results if treated as No. 1.

No. 3 is still more elaborate, and offers opportunities to the amateur carver, as the centre pieces and portions here and there may be carved more or less, according to the skill and taste of the worker.

No. 6.

PANELS FOR OVERLAY WORK.

Nos. 4 and 5 are neat and not over-elaborate, and are within the range of most scroll-sawyers. The shield in No. 4 is composed of two thicknesses of stuff. The top piece may be carved and picked in with gold and color, or painted to suit taste. No. 6 is a very graceful piece of fretwork, and is well adapted for the panels or doors of an old-time sideboard. The shield might be a carving—in low relief—of suggestive design—fruit, fish or fowl, or the designs may be painted in low-tone colors.

We have seen fretwork of this kind used on dining-room doors, where the original panels were flat and unrelieved. In this case the fretwork was surrounded by a band of stuff from one-half to one inch in width, and the same thickness as the fretwork or overlay. The work was then fitted in snugly between this frame, and either glued, cemented or bradded on to the panel. The whole was then painted over with suitable color, and, when dry, the fretwork was painted again in a much darker or lighter tint of the same color. The effect is pleasing and comfortable to the eye.

In preparing these designs for special purposes several things must be taken into consideration to produce satisfactory results. First, the sweep of the saw. Some saws will not take in more than sixteen inches in length or width. This would limit the stuff to be cut to something less than two feet in length, if the stuff is twelve or more inches in width. When this is the case, and more length of overlay is wanted than the saw will take in, the design must be made so that it will cut in parts in places where the least number of junctions occur, as *x x x x x*, Nos. 1, 2 and 3. When the designs are sawn out in sections after this manner, the parts may be nicely fitted together before they are fastened in place.

When the panels are long, the designs might be doubled—that is, two pieces of the same design might be used, butt to butt, to fill the panel.

Six pieces of any one of these designs may be cut at once with one of Barnes's $20 velocipede saws, if the stuff is not more than one-quarter of an inch thick.

Overlay work is easily executed, and when judiciously and neatly done, gives good satisfaction for the labor expended.

Amateur Wood-Carving.

BY LEO PARSLEY.

HAVING, in a measure, explained in previous papers the uses of the various tools and appliances required by the amateur wood-carver, I will now proceed to give such directions for their use as will enable the reader to commence operations. It may be readily understood that it is almost impossible to give written instructions for every detail of the wood-carver's art that would be clearly intelligible to every one; I shall therefore give general directions only as to the treatment of the designs, leaving the treatment of small details, such as the number of petals in a rose, or the curl or twist to be given to a leaf, for instance, to the individual taste and skill of the amateur.

The grand secret of success in wood-carving is to obtain a complete command over the tools, so as to make them obey the will of the operator, irrespective of difficulties in the shape of the grain of the wood, etc. To obtain this mastery over the tools, practice is the only remedy, and no matter how simple the design may be, it will be found that continued practice is the only thing to accustom oneself to the use of the tools.

The proper way to hold a carving-tool is to grasp it firmly with the left hand, so that the lower part of the hand comes to within an inch of the edge of the tool, and acts as a guide to it, the right hand grasping the tool by the top of the handle, acts, so to speak, as the motive power.

It will be found that with this method of holding the tool, more power can be exercised, and at the same time there will be less chance of those unlucky slips of the tool which so frequently mar the effect of a piece of work.

There are various methods adopted in carving; some workmen will only slightly "block out" the design in the wood, and

leave the greater part of the work to be done in the finishing. Of course, every piece of wood intended to be carved is subjected to at least two processes, viz., the roughing, or blocking out, and the finishing process. The first thing, then, to be done, after the design has been carefully marked or traced on the wood to be carved, is to cut away all waste or superfluous wood, such as sinking the groundwork of a panel, for instance. When this is done, the outlines and shapes of the leaves, etc., of the design should be roughly shown, and after the design has been thus blocked out, it is advisable to thoroughly sharpen the tools required, and then to carefully finish off every detail. I have, in Fig. 1, given a simple design of ivy-leaves, which may easily be utilized as a panel. We will suppose that the piece of wood intended for the panel has been smoothly planed and squared, and is either oak or walnut and not exceeding half an inch in thickness, and that the design has been drawn on the wood, as at Fig. 1. The work should be firmly fastened down to the work-bench by a carver's bench-screw or other efficient device. A good holder can be made by taking a piece of pine about one and a half inches wide and one inch thick and six inches long; saw out a piece from one end a little less than the thickness of the stuff to be carved, running down the stuff about a half an inch and across the widest way; this will leave a jog or shoulder on the piece; run this shoulder against the edge stuff, letting the upper part overlap. Then screw the piece tight down to the work-bench, and it will hold the work solid. Sometimes it may be necessary to use two or even three of these holders to make the work firm and solid.

Having secured the work firmly to the work-bench, take a parting tool and work it carefully around the *outside* of the outlines of the leaves and stems and *inside* of the panel mouldings, and then with tools of the proper shape and the mallet, set in the lines made with the parting tool. Cut away all the sunken portions of the design (Fig. 1) with hollow tools. The groundwork of the design should be about ¼ or ⅜ of an inch deep, and when this depth is reached the "router" will be found to be the most convenient instrument for regulating the depth. The cutter of the "router" should be set to the depth required, and then by pressing it firmly, and working it sharply backwards and forwards, a level ground will be obtained.

In setting out the outlines of the leaves,

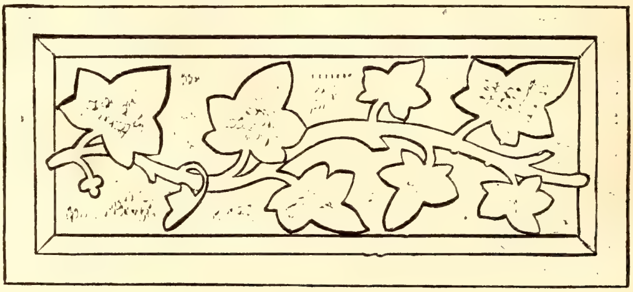

Fig. 1.

etc., it will be better to cut outside the lines, and care should be taken to cut down perpendicular; otherwise, if the leaves are undercut, the shape will be spoiled when they come to be finished. Bent flat tools are used for clearing away the wood when making the groundwork, and for clearing out the wood that cannot be taken out with the "router."

When the groundwork has been so far finished, a commencement should be made in forming the mouldings, and roughly shaping and giving the required turns to the leaves and stem, but no finishing touches should be put on until the whole design has been gone over in this manner.

It is better in doing this to use hollow tools only, leaving the flat tools to finish off the work with. Of course, in setting in the outlines, the tools that are the proper sweep to fit the lines should be used.

When all the design has been carefully gone over, as above described, there re-

mains only the last process to go through, and we begin this by first of all carefully finishing the moulding, which in this case is simply a flat hollow, and then proceed to carefully finish off the leaves and stem, and rectify any little irregularities of the groundwork.

In doing this we shall find the advantage of the frequent use of the hard brush to brush out the small chips and cuttings. When this is done, we commence to use a punch for the groundwork, until it has all been gone over, and then the veins of the

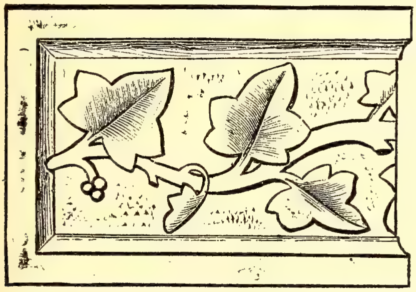

Fig. 2.

leaves require to be put in with a veiner, and the stems require to be roughed, so as to give a natural appearance to the work. The various tools have been previously described, and it will be found

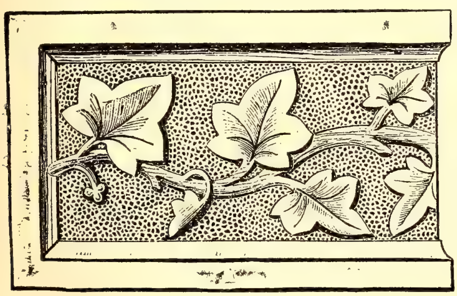

Fig. 3.

that about eighteen will be necessary to work this design. When the work is finished, it may be either brushed over with boiled linseed oil or left plain, as may be desired, but sand-paper, on no account, should be used. Fig. 1 shows the design drawn on the surface, Fig. 2 a part of the design blocked out, and Fig. 3 a portion of the panel completed.

It will be an easy matter, in this design, to continue it to any length. I would advise the amateur to procure a natural leaf of the ivy, and study it closely during his operation on this example.

A School-Boy's "Handy Case."

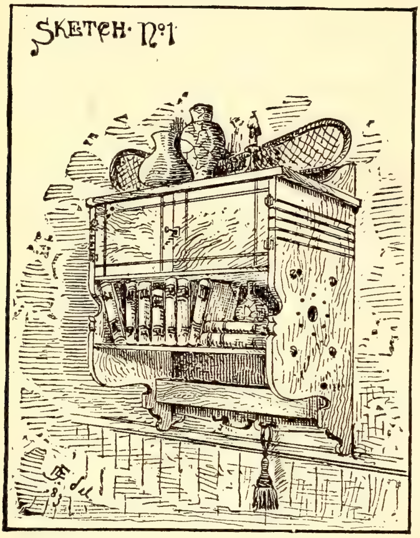
BY EDWARD DEWSON.

THIS simple and useful little case may be put together almost entirely with screws, so as to be readily taken apart if desired, a mode of construction which is termed "knock-down," and is oftentimes very convenient, but requires a little more care in getting out the various parts than does the more common method of "gluing-up."

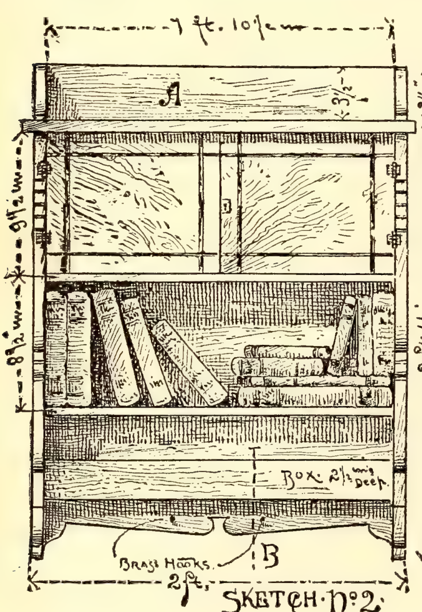
The top space is filled by two doors, lapping one over the other, on a ¼ inch rebate, shutting against the centre partition, and hung with simple brass hinges, allowing the doors to swing entirely clear, for reasons that will be shown shortly. The cupboard partition should be made separately in box form, as shown by Sketch No. 4, of ¼ inch white wood, planed and smoothed down to an even 3-16 inch; follow the measurements, and let them be housed or set into the sides, as shown, and finished with one coat of white shellac, rubbed smooth. This method will be found handy, as the box may be readily removed when the space is wanted for books or larger objects, and be put carefully by for further use. The doors are allowed to swing clear, that this box may slip readily into place.

Below this cupboard is a shelf, allowing an inch clear space for the school-books in constant use, where they may be placed every night, to be readily found in the morning, and so obviate the necessity of hunting the house over at the last moment for a missing book, as is very often the case with school-boys. Below the shelf is a little box 2½ inches deep on the inside, to hold the pencils, tops, marbles and numerous other odds and ends pertaining to boyhood. Make of any good wood, ash or cherry preferred, as being

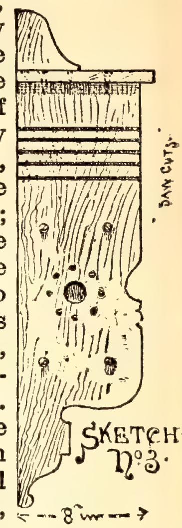
more suitable for this style of work; although if made of good clear pine—avoiding any tool marks—filled and finished

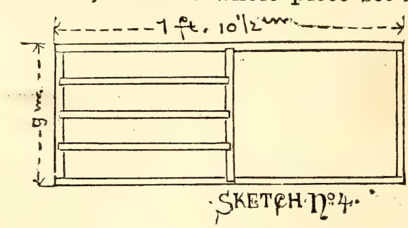


with two good coats of clear white shellac, well rubbed down with fine emery paper,

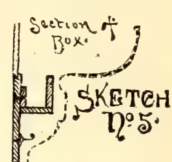


a very neat and pretty case will result. The sides and top shelf are made from ¾ inch stock, each side piece being 8 inches wide; cut outline according to pattern given in Sketch No. 3, which should be carefully enlarged to the full size required. Between the top shelf and bottom of cupboard run five sharply cut saw lines, as shown, and below this cut the simple pattern indicated; this last feature may be cut clean through the stock, if desired. The top shelf is 2 ft. 1½ inches long, and 8¾ inches wide, which allows a ¾ inch projection on front and sides. Shelf is fastened to the side pieces by four 1¼ inch flat top screws; the wall piece, A, on Sketch No. 2, is ¾ inch stock, 1 ft. 10½ in. long and 3½ inches wide, glued between the two small side brackets of same thickness, and the whole piece set into





top shelf with dowels; the bottom bracket, B, on Sketch No. 2, extends up behind the little box, as shown by the section, Sketch No. 5; the back fastens on to this by small screws, and on to bottom of top shelf; this back is ¼ in. white wood, glued up in strips the size required, and should be stained on the inside in imitation of the wood used. If that wood be dark, or simply filled and shellacked, light wood is used.



The ½ inch shelves are rounded on the front edges, and are fastened in place with 1¼ inch silver-headed screws, as shown in sketches. Should grained wood be used, select the prettiest pieces for the

doors; cut the cross lines on surface neatly, finish with a simple brass key-plate over the lock, and be neat and careful in putting the lock in place.

After putting together the case, fill with a good "wood-filler." I would suggest Wheeler's as being good, having used it, although others may be as good or even better. Follow this with a heavy coat of white shellac, which should be allowed to thoroughly harden. Then rub down smooth with emery cloth or good fine sand-paper; repeat this with a thinner coat, and rub lightly till a soft, even finish is obtained.

Sketch No. 1 shows the completed case. As will be seen, two neat brass hooks are suggested at the bottom, the use of which is obvious.

By observing and following carefully directions and drawings as given here, any boy at all handy with tools should be able to put together this little case, which I feel sure he will find useful when completed and put in place in his room.

How to Make a Combination "Shooting" Board for Amateur Work.

THE common shooting board for making square joints, and extremely handy for use in fitting drawer fronts to their respective places, is too well known to need any description whatever. In like manner, it is needless to say anything about the common mitre shooting board, as this is about as familiar as the other. The advantage claimed to be derived from the use of the tool about to be described is, that it combines the usefulness of both square and mitre shooting board in one, and is almost as simply and as easily made as either. A very crude form of this tool is shown by Fig. 1, and consists of two fixed blocks, one at right angles to the long edge of the board on which they are fixed, and the other at an angle of 45 degrees. This simple contrivance is very useful for mitres on small mouldings; but if a piece of wood of any considerable width is required to be shot, the mitre block would be in the way; the width of the board which might be worked on this tool depending altogether upon the distance between the two fixed blocks. What is wanted, then, is a shooting board with a single block that will work both square and mitre joints, and perform either duty equally as well as a separate tool would do. The block must therefore of necessity be a movable one, and there are several methods whereby this desired end may be attained. The best of these

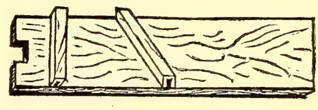


Fig. 1.

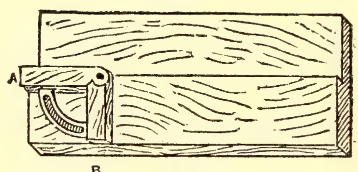

Fig. 2.

methods is, in our estimation, the one indicated by Fig. 2, and which is the tool at present under notice. It is one which, while simple and inexpensive in construction, and quite capable of performing the work both of a mitre and an ordinary shooting board, is yet very easily adjusted, and is one which cannot get out of order. Without any further preface, we will proceed to describe the best method of manufacturing this tool.

Procure a piece of wood about 2 ft. long, 8 in. wide, and 1 in. thick. Plane this up, and upon it glue another piece, 24 in. by 4 in., and ¾ in. thick, so as to form a rebate along one face. If the thicker wood can be obtained, cut a piece 24 in. by 8 in. and 1¾ in. thick, and take the rebate, 4 in. by ¾ in., out of the solid wood. A section of this board is shown by Fig. 3.

Fig. 3.

Fig. 4.

Next cut out two pieces of wood, each 4 in. long by 1¼ in. square. These are to be blocks, one of which is fixed as a guide to the other, which latter is movable. Clean

and cut them to the shape as shown by Fig. 4. The ends of these blocks are mortised and tenoned together somewhat after the same style as a common 2-foot rule is hinged. When this joint has been made, fix one of the blocks on the face of the board which forms the "bed" or foundation of the tool. This block is marked A on Fig. 2. Before putting on the other block, a piece of wood must be cut out, shaped something like a quadrant of a circle. This should be about $\frac{3}{8}$ in. thick, and must be let into and screwed on the under side of the movable arm (Fig. 5). The latter may now be fixed on to the end of the fast block in the manner shown on Fig. 2. This is done by boring a $\frac{1}{4}$ in. hole through the tenons of each block, and then fitting in a plug, so as to allow the block to be moved from side to side. Now put a screw through the slot in the quadrant-shaped piece of wood into the bed of the shooting board, in such a manner as will just allow the arm to be pulled round to an angle of 45 degrees to the long edge of the tool, and will there stop it from going any further by catching the end of the slot in the curved piece. This same screw will also catch the arm when it is put back at a right angle to the board, and prevent it going any further in that direction. Fig. 2, which shows the block placed to allow a square joint being made, and Fig. 6, which shows the arm pulled back in order that a mitre may be shot, will help to make clear any indistinct portions of the preceding description of this tool.

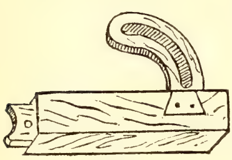

Fig. 5.

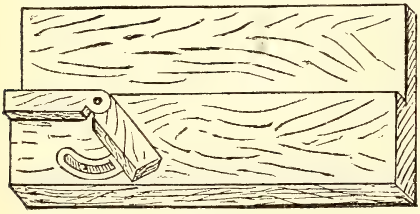

Fig. 6.

Almost any sort of wood will do for the making of this tool, provided it be sound. We have even seen ordinary pine used, but in our opinion this is rather too soft for constant usage, and very soon gets knocked to pieces. However, any sort of hard wood will do, and if made out of mahogany throughout, a really handsome tool is the result.

The total cost of manufacturing such a tool as the one described need not be more than the price of the wood. This will cost about seventy-five cents if made in Spanish mahogany, and about fifteen cents less if made in Honduras.

The Manufacture of Baseball Bats.

BUT few people outside of baseball players have any idea of the great number of bats used in a year. It is estimated that between 4,000,000 and 5,000,000 of these implements were sold during the year 1882. To manufacture these bats nearly 30,000 cords of wood must have been consumed. These are, seemingly, startling figures, but the facts appear to support them. Michigan manufactures more baseball bats than any other State, for in that State the best wood is found. Bats used by professional clubs are now almost invariably made from ash, and even this wood, strong and elastic as it is, must be of the best quality and perfectly seasoned in order to stand the strain put upon it by the baseball players of to-day.

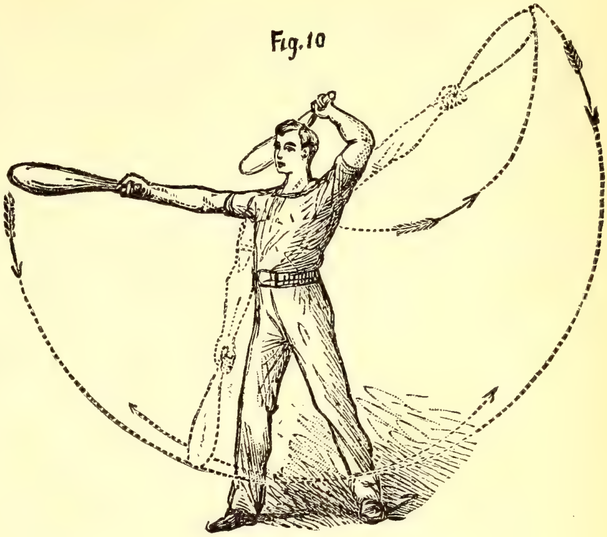
The majority of bats made, however, are intended for amateur players, and are manufactured from American willow.

The willow bats are much lighter than those made from ash, and consequently are much more popular with young players. There are bat manufactories in almost every State of the Union, but the largest and most noted, besides those in Michigan, are in Massachusetts, New York, Rhode Island, Illinois and West Virginia. The bats are turned out by machinery, and, as they are of uniform size and pattern, a lathe and the right kind of timber are the only requirements for a manufactory. Recently orders for bats have been received from European

countries, Australia, and Japan, indicating that the superiority of these goods is becoming known all over the world. Many of the firms manufacturing base-ball bats also produce the wooden implements, balls, and other goods used in the games of cricket, croquet, etc., and it is stated that the demand for the manufacture is much greater than for many years past. As the season for out-door games approaches, the call for all goods made will materially increase, and the producers are preparing to meet the anticipated large volume of trade.

M. C. GRAY.

Fig. 10



Indian Clubs, and the Way to Use Them.—III.

BY JAMES A. SQUIRES.

EXERCISE 8 (Fig. 10).—This is a simple swing backwards and forwards, each club being swung alternately in front of the body and behind the head. When the right club is extended at arm's length, almost straight from the shoulder, the left club is passing behind the head, and *vice versa.*

Exercise 9 (Fig. 11). This is exactly the reverse of Fig. 5. The illustration will show the movement.

Fig. 11

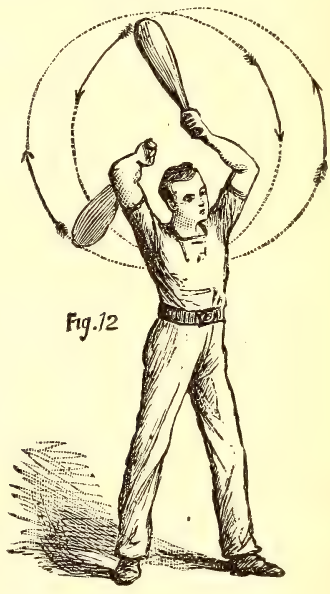


Fig. 12

Exercise 10 (Fig. 12). This is very effective, and if performed rapidly and

neatly is sure to elicit applause from an audience. It consists of circles behind the head with each club, in the direction shown by the arrows, one club passing in a downward direction while the other is swinging up.

Exercise 11 (Fig. 13). This is not very

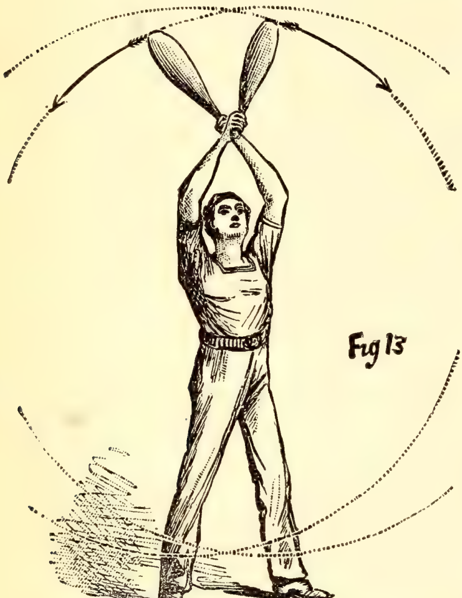

Fig 13

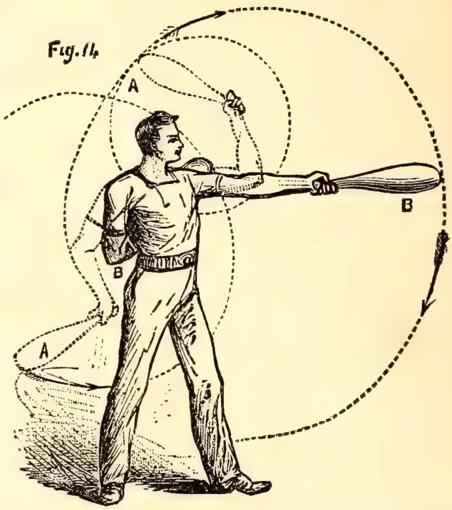
difficult to perform. Keep the arms straight, and beware of a collision. The clubs are swung in a circle across and in front of the body, passing one another twice in their course—once when above the head (as in the figure) and again in front of the legs.

Exercise 12 (Fig. 14).—Now this *is* difficult, and will take a long time to learn. It is a complication of Exercise 3. Commence with that, and, having got the clubs into a good swing, check the course of the right arm, slightly decrease the pace of the left arm, and throw the right club sharply behind the body, until the base rises a little above the left shoulder (see Fig.); then swing it back to A and B, and continue the original circle, all this time keeping the other club (the left) traveling in a circle, until it becomes its turn to effect the movement that the right one has just completed, and so on, first with the right club behind the body, and then with the left in front, and *vice versa*. This is one of the best and prettiest exercises yet described, and will entail long and patient practice; but when

Fig. 14



thoroughly acquired it will well repay the perseverance expended upon it.

Our Birds.

BY C. W.

SPARE moments may be very pleasantly spent in watching the birds. It may be thought that nothing new can be learned about our more common birds, such as the robin or chipping sparrow, but I think that many interesting facts will be noted by any one who gives a little time to their study.

But I hear some one say, "Well, that is all right, but those of us that live in the city don't have much of a chance to watch birds." Now here is just where I disagree with you, for I live in a city and yet in the course of a year I generally fill a good-sized note-book. Among the species that I have noted during the past year, here in the city, are the night-hawk, bluebird, catbird, Baltimore oriole, English sparrow, purple grakle, cow-bunting, brown creeper, crow, kingbird, chipping sparrow, song sparrow, house wren, humming-bird, Phœbe bird, white-bellied not-

hatch, robin, black snowbird, chimney swallow, and yellowbird or goldfinch. Many more have been noted within the city limits (Syracuse, N. Y.) I mention these simply to give some idea of how many birds are to be found in the parks and yards of our cities.

While birds have specific characteristics or habits (i.e., habits common to all the individuals of a species), they also have individual peculiarities. These latter are often the more interesting, and often show something *very much like reasoning power.* To trace the relations of cause and effect in the actions of a bird is both interesting and instructive. Another branch, and one that may be very profitably pursued in connection with the study of their habits, is the study of the general anatomy (if I may so use the word). See how perfectly each part is adapted to its own particular use, and how all are modified in accordance with the food and habits of the species under consideration. Examine the plumage of a chickadee; how fluffy the feathers are, and how well adapted to resist cold. Do you wonder now that the little fellow does not mind the weather? Look at his feet and compare them with those of a vireo; what broad soles both have, and how well adapted for perching.

But do not think that only the habits and formation are to be studied. When you have a good collection of notes at your disposal, you are just ready to take up a new branch of the study—that of collecting and examining the various evidences of reasoning power which you have noted. Begin with some fact and ask yourself the question "Why?" and answer it. Collate all the parallel instances and form your theory. Then, after it is formed, be ever on the watch for facts to support or disprove it. But there is no need of my mentioning the different branches of the study; a few weeks' experience will furnish more suggestions than could be easily enumerated.

Let us next examine the means of study. A gun is indispensable for general field work or for an "ornithologist," but is usually out of the question in the city. The best substitute, and one that is better in many respects, is a field-glass. An ordinary telescope or an opera-glass will do. The use of the field-glass has been minutely discussed recently by a writer in "The Ornithologist and Oologist." Perhaps I can do no better than to quote some of his remarks:—"A bird thoroughly shot with the glass is forever alive and fixed in the mind, and a hundred little ways and habits have been noted, which would have been entirely lost if shot in the usual manner. To know a bird thoroughly it must be watched very closely, and it is often the case that many habits and queer ways are noted before enough of the descriptive points are obtained to determine the species. * * * Having obtained all the points as to size, color, particular markings, etc., with the aid of any good text-book, the species may soon be determined. There are some difficulties in the way, and at first some errors may be made. With the novice the female purple finch might be taken for a sparrow, and the hairy and downy woodpeckers would, perhaps, cause a little trouble, but in a short time nearly all birds will be recognized at first sight. A bird should be studied for color against a dark background; if seen in the face of strong sunlight everything becomes black. * * * Measurements obtained at glass range may be quite easily determined by comparison with the dimensions given in the text-books of some familiar bird like the robin or bluebird. For small birds the chickadee or some familiar sparrow can be taken." I will only add that the note will often be of great help in determining a species. Many use bird-lime and snares, but I have had no experience with the former, and little luck with the latter.

A study closely connected with that of our birds, or rather embraced in their study, is that of birds' eggs. Many, myself among the number, take a peculiar interest in these, but I will leave that subject for another time.

In conclusion I will make a few general suggestions. Always keep a record of the notes you take from day to day; write it out fully and minutely. If you notice a

bird doing something that you have previously noted, don't omit it and say to yourself, "I've put that down," but make a note of it. This is the only way in which you can decide whether you have noted an oddity or not; habits are simply actions repeated. Among the aids to identification I will mention the "local list," and access to a good library. A "local list" is a list of the birds that occur in a given locality, and is generally based on several years' observation in that locality: it helps by narrowing down your circle of search. In nearly every city or village is a public library, where you can find works on ornithology.

The rising generation will furnish our future ornithologists; but my greatest desire is to do what I can to make the study more universal, for none but good results can follow.

Casting in Plaster of Paris.—II.

BY MARK MALLETT.

IT will be well to make some arrangement by which our cast can be hung up. We may bore two holes through the middle of the top rim of the mould, and put a loop of copper wire through them, bending its ends so as to give them a firm hold, and so arranging it that it will be well imbedded when the mould is filled with plaster. We use copper and not iron wire, because the latter would certainly rust, and sooner or later cause the plaster to become discolored and split. The mould is now ready to be filled, that is, we may now proceed to make the actual cast. Had our work been of a more particular nature we should now have used superfine, but we have decided that fine plaster will serve our purpose. Still, whichever it may be, we must be particular to mix it with the greatest care, by the rules already laid down. Clean water must be used. When ready the plaster must be poured into the mould, and the latter gently shaken and moved from side to side, so as to cause the fluid to run into every cranny, and to leave no air bubbles between mould and cast. The bellows may again be used to advantage to blow the plaster well into the under-cuttings. Lose no time till a covering has been given to the whole mould, for the liquid plaster will quickly thicken and begin to set, and it will not then flow into corners and cuttings; go on till you have laid a coating of fine plaster, a quarter of an inch or more in thickness, over every part of the mould, and then back up with coarse till your cast is thick enough. An unpracticed caster should not venture to leave his casts too thin; it is false economy. They must be strong enough to resist the blow of the mallet used in chipping off the mould. The thickness must to a great extent be regulated by the size and nature of the model; for such a one as the present, three-quarters of an inch, in the weakest parts, will suffice.

Almost directly after the mould is filled, you can begin to smooth and trim off the back of the cast, for this you will do most easily whilst the plaster is still soft. By the time that this is done the cast will be hard enough for you to begin chipping away the mould. The cast should be laid on its back on a table or other sufficient support: if it can be placed in a sloping position it will be easier to work at, and the chips will fall away more readily. Your tools must be a mallet and a blunt chisel. The edge of the latter should be ground off round.

The outer mould and its irons will be easily and quickly removed. By a few bold strokes they can be fetched off in a few pieces, for the clay which has been daubed between them and the inner mould will cause the two to part readily. The outer mould being cleared away, we next have to remove the inner mould.

We have now come to the most interesting part of the whole process. No small pleasure can be promised to the operator whilst with the removal of the inner mould he sees his model gradually reappear in a new, solid, and beautifully white material. The inner mould must be chipped off in small pieces, and with great care, lest injury be done to the cast beneath. It is safer to keep the chisel, whilst working, almost at a right angle to the surface. And now the value of the tinted mould will become apparent. The difference of color will enable the operator at once to distinguish between the mould and the surface of the cast, when the latter is reached, and thus all danger of cutting into the latter by mistake will be avoided. If the directions given are followed with care, the inner mould and cast will separate with sufficient ease, though not so freely as the outer and inner moulds had parted.

A clean soft brush may be used to remove chips from the surface, and the bellows will again be found useful to clear out hollows and under-cuttings.

When the mould has been entirely removed, notwithstanding all our care, we can scarcely hope to find the cast wholly free from imperfections. Some projecting part may have been chipped off, there may be holes caused by air bubbles, or others made by chance slips of the chisel.

In the case of a small breakage, the professed moulder sticks on the piece with a little shellac dissolved in spirit, which he keeps by him in a bottle. This is the quickest way of mending. But it may be done quite as effectively and more neatly with a little liquid plaster, mixed thin

For stopping holes of any kind, plaster must be mixed in the ordinary manner, and then "killed;" that is to say, you must allow it partially to set, and then beat it up with a little more water. Without this precaution it would set harder than the surrounding parts of the cast, and be easily distinguished from them in appearance.

In the next paper I shall speak of the few simple tools used in casting, and give a brief description of wax moulding and piece moulding, and the methods to be followed in making elastic moulds, and taking castings from natural objects.

Painting on Silk or Satin.

IT is more prudent to begin painting on satin, as its smooth surface presents fewer difficulties than the texture of silk. The objection to painting on satin is this: the gloss of the surface is exceedingly trying to the eyes; so much so that, during the past two years several professional painters have been compelled to give up decorating any materials except canvas or paper. Therefore, do not face the light while painting; wear a shade—such shades as wood engravers use. You must test the kind of satin to paint on yourself, by trying a sable brush thick with Chinese white on a small sample. If the satin surface is easily moved by your brush, then give that piece up, and paint on a firmer woven kind. It is poor economy to paint on cheap satin. Keep the satin firmly and smoothly stretched on a drawing board or pasteboard with artist thumb tacks, because these tacks make very tiny holes, and have large flat heads. If you are accustomed to the use of oil paints, then begin by squeezing out the tube colors on blotting-paper, because the paper will quickly absorb the oil with which the paint is mixed, and therefore prevent an ugly, greasy stain on the satin. The paint, not the material, is prepared. It may take your painting one week or more before the satin is perfectly dry. This is one objection to painting in oil. The chief advantage is that as dampness will not affect it, rain does not ruin the costume painted with colors. To prepare the silk or satin for painting, simply lay on ox-gall with a brush over the place which your design is to cover. The ox-gall is used to overcome the oily, greasy nature of paint mixed with oil. Use plenty of paint. Choose a bold design. Avoid the embarrassments of Nature's wealth of leaves. Selection, not servile imitation of Nature, is the only broad, enduring, and therefore safe rule, in design. In selecting a design, remember the flowers and leaves must not hide each other. The leaves should not be represented in a mass, because, from the nature of the material on which they are painting, it is impossible to give all those wonderful gradations of color with which a ray of sunlight illuminates the weeds in a country road. Decorative art does not attempt the impossible; its rules simply save you from the blunders committed during the infancy of the human race. Black satin is the easiest to begin on, as far as your design is concerned, because this black background brings out your slightest effort. Black harmonizes colors. At first, aim at only three distinct hues in a leaf: 1st, for general color; 2d, for the shade; 3d, for highest light. By hue is meant such a combination of cinnibar, green and burnt sienna as you would blend with a palette-knife, to represent the leaf of the trailing arbutus, for example. Blend only with your palette-knife on your palette; to make the painting effective, no blending must be attempted on the satin. The same rule applies to silk. Black is the easiest for a beginner. If possible, arrange your design so that the stroke of your brush, in painting will pass parallel to the rib of the silk, and not across the woof of either silk or satin. Silk or satin is most easily painted with water colors, if you have not long experience in painting in oil. As to durability, a dress painted for the wedding garment of a Revolutionary beauty was in a good state of preservation at the Centennial celebration of 1876 at New Haven. The dress was white silk; the design was painted in several shades of blue. There was no minute work; large, bold curves cut the white silk not covered by the blue arabesques, into graceful white forms. Paint, therefore, is a preservative. Silk or satin dresses, if painted properly, may be bequeathed from one generation to another. It will then "pay" to take some trouble to paint a good design. TRACING.—If you are timid about painting at once on the silk, use tracing paper, because lead-pencil marks cannot be rubbed out easily. Go over the paint line left by the tracing paper with thick colors, or paint, mixed with Chinese white. Transparent colors, laid on silk, will run into irregularly ugly shapes. The preparations used on silk to stiffen it and fill up the texture are various. The danger to be avoided is changing the shade of the silk or satin; therefore prepare the paint, not the silk. It is less of

a risk to use no preparation on the silk or satin. When no preparation is used, the first pigment laid on the satin should be a body color, i.e., the paint should completely hide the hue and texture of the satin. For example: vermilion is unchanging red, perhaps the best example of natural body color, and is seen to great advantage in the better class of Japanese and Chinese painting. Use a white sable brush, and charge it with as much color as possible. When dry, you find a smooth, brilliant red, no matter on what shade of satin you have painted. Try the same proceeeding with rose madder, and though the color looked bright when wet from your brush, it dries a dull, nondescript hue. You are not successful, because rose madder (though a beautiful permanent red) is not a body color; therefore give it a body by mixing it with Chinese white. Do not be dismayed when you see that it is impossible to keep the beautiful red color after adding Chinese white. Go on—add more white. Remember that this mixture should be laid on as thickly as the vermilion, in order to produce a perfectly smooth surface on which you may paint. When perfectly dry, pure rose madder, painted over this surface will give you the delicate red you need. Mixing Chinese white with greens causes them to assume a bluish hue. Counteract this by adding yellow, gamboge, yellow ochre, or Indian yellow. White, mixed with any color or hue, is called a tint. It is important you should use Chinese white only, because that is permanent, and white is the foundation of all tints. Use a bone stiletto, ivory paper-knife, horn palette-knife, or wooden brush handle in mixed colors, as many colors are injured by contact with steel. The exception to the general rule of laying on the color as thickly as possible is this: When you wish to give the effect of white flowers in shadow, as the semi-transparent appearance which is the characteristic of many flowers, add water to the Chinese white till it is almost liquid, and by painting this quickly over the satin, the color of the material, showing partly through the thin white, produces a grayish effect of exceeding delicacy and beauty. Colors bought in powder are better adapted than moist or cake water colors for painting on silk and satin, or, indeed, any textile fabric. Powder colors, such as used for wax flowers, are fine enough for you to mix with Chinese white and gum-arabic. Mix by grinding all at once with small glass muller or the bottom of a small glass bottle. The reason that powder colors are used by the French painters of fans is, because there is more body than when the paint is mixed by the machinery of the professional color maker. Vehicles.—No matter how finely you grind powder paints with water, something more must be added to keep the colors from rubbing off as soon as the water has evaporated. Whatever may be successfully used to fix paints is technically termed a vehicle. The difficulty to be looked out for is this: If the satin be neither white nor black, some color has already been used on the texture, which may be affected by some of the vehicles which are easily used on white paper; therefore try a small piece of satin before deciding which vehicle is to be used. Among the vehicles that have been most used in painting on silk are gum-arabic, gum ammoniac, gum tragacanth (so often found in a grandmother's paint-box), starch—domestic—but possessing valuable properties in the preparation of paper, as well as textile fabrics—rice water, flour paste, the white of an egg (the chief size used in mediæval monasteries) and white castile soap. The most useful, with the least deficiencies, is gum-arabic. It should be bought in lump, and not in powder. Dissolve in cold water, strain through a white muslin, and keep in a wide-mouthed bottle (with a cover) by your side while painting. Mix your paints with this, instead of simply water, if you are using moist or cake colors. Gum-arabic is best dissolved fresh each day, because this, like all other gums, contains an acid which acts against the preservative qualities of this gum in a liquid state. If it is inconvenient for you to mix fresh every day, then add a little alcohol to the gum-arabic, or counteract the action of the acid by an alkaline substance, take one scruple of carbonate of ammonia to an ounce of gum, dissolved in three ounces of water; shake the mixture well. The carbonate will purify the gum-arabic, preserve it for long use, and cause the paints to work more smoothly. Gum ammoniac, dissolved in water, forms a milky fluid that dries transparent. No fly or insect of any kind will approach the satin if this gum is used in mixing the paints. And in this respect ammoniac has a great advantage over colors mixed with honey or sugar-water. It also gives a gloss to the colors, and acts somewhat like a varnish over the water colors. Gum tragacanth, dissolved in hot water, is useful when the paint is not to appear glossy. Starch, made as if for household use, and used only when made fresh each day, is a good working vehicle. Rice water is used by the Chinese to mix their colors. It must be remembered that their brilliant imitations are painted on rice-paper. Flour paste, made without lumps, makes a cheap and convenient vehicle for the mixture of colors. The white of an egg is perhaps the most venerable vehicle for paints; the yolk has been used

with yellow and brown paints. White Castile Soap.—Keep a piece by you, and constantly pass your moistened brush over the soap, so as to mix its white body with your cake or moist paints. In conclusion, remember that the paints you have—whether cake or moist colors—may be used on silk or satin; but if you intend painting a dress, or contemplate using very much paint, it is cheaper and quicker to use powder paints. Use only the best paints. Thus far, the English water colors are the best. The Tyrian colors, which are made by a New York firm, are better than many French and German paints for painting in body color. They are superior to other cheap paints. —*Art Interchange.*

Our Girl's Department.

This department is intended exclusively for "Our Girls," and we hope to make it both interesting and instructive, and to this end we ask our young lady readers to assist by contributions, suggestions, or illustrations. There are thousands of little things that can be, and have been, made and done by young ladies, pertaining to decorative art, needle-work, etc., etc., that would be gladly followed but for a want of knowledge on the subject, and we know of no more pleasing task for a lady than that of teaching her younger sisters that which they are anxious to learn, and which may prove of real benefit to them in the future, as well as being useful and interesting for the present. We trust we will have no difficulty in persuading those who have something nice to show or speak of, to make use of this department. Remember, it is open to all, and if you have anything worth knowing suitable for this column, send it along, and we will give it our best attention. Do not be afraid to write because you may fancy your composition is not perfect, or have other scruples of a similar kind. Do the best you can, and leave the rest to the editor of this department, and we are sure you will be pleased with your work.

FIVE great enemies to peace inhabit with us, viz., avarice, ambition, envy, anger, and pride, and if these enemies were to be banished we should infallibly enjoy perpetual peace.—*Petrarch.*

—No cord or cable can draw so forcibly or bind so fast as love can do with a single thread.—*Burton.*

—You remember the fairy who was so good-natured that any weapon aimed at her changed its quality: stones became balls of silk, and arrows became flowers. The moral of the fable is evident. Be but liked and you will not be censured for your failings (if you have any), nor envied for your good fortune.—*Sharp.*

—When the poet Carpani inquired of his friend Haydn how it happened that his church music was always so cheerful, the great composer made a most beautiful reply. "I cannot," he said, "make it otherwise. I write according to the thoughts I feel. When I think upon God my heart is so full of joy that the notes dance and leap, as it were, from my pen, and since God has given me a cheerful heart, it will be pardoned me that I serve Him with a cheerful spirit."

—Yellow silk tapestry is combined very effectively in upholstery with capucine shades in plush.

—Plush is no longer dependent for decoration upon oil paint or embroidery. The latest style is to carry out an unconventional design in bronze paints, the result appearing like work inwrought in relief.

—A fancy is shown for trimming the ends of plush table scarfs with cone-shaped pendants in plush, no two adjacent ones being of the same color, while all repeat or harmonize with the color of the embroidery.

FLORICULTURE FOR GIRLS.

"Roses musky-breathed and drooping daffodilly and silver-leaved lily!"

Who would not court such sweet companionship? I wonder if girls realize half they miss by neglecting to spare a little of their time for the cultivation of flowers? It is the Eve work in the world. No work in itself more delightful, none more healthful, none that gives greater results for the labor expended; yet as a rule, while a maiden will spend hours over fancywork, or some counterfeit presentment of a flower, the few minutes given to plant-tending are thought much of, and the plants dubbed "ungrateful" if they don't flourish tremendously in gratitude for having a little water poured over them and a dead leaf or so picked off.

It may happen, in the autumn, that the house daughter thinks, "I will have a few house-plants this winter," and she thereupon devotes a morning to potting some of the garden plants, gets quite enthusiastic over it, looks with triumph at the end of the day upon her work, and

expects wonderful returns for her trouble. Three weeks later what is the cry? Why, that "these, though fed with careful dirt, are neither green nor sappy." Zeal without knowledge will not go far. What more dreary sight than a sickly plant? It affects me as does the sight of a sickly child: I cannot help feeling that it suffers—that its existence is no pleasure to it. Though I have not made it part of my creed, my instinct is, as was Wordsworth's, "that every flower enjoys the air it breathes," and if it is deprived of air, or its lungs obstructed, must it not suffer accordingly?

Plants call for scientific treatment. What is science but knowledge—you must know your plants before you can manage them—and the fascination of learning the nature and needs of growing things is, that you can learn and learn, and there still be more to know beyond. You learn the rules for treatment of classes, and then for families of plants—but lo! they turn out to be like families of children—(plant nature is much like human-nature)—unthought-of characteristics crop up in unexpected places: some unnoticed difference in its surroundings, some small variation in its conditions, and the plant develops peculiarities for which you have no precedent, and you are forced to study its peculiar needs and minister to its particular tendencies. But, if you learn to love your plants, you will delight in their vagaries, and keenly enjoy every fresh demand they make upon your intelligence.

The distinctive characteristics of different classes of plants—as widely distinct as different nationalities of people—render them the most charming of all aids in house decoration; if you have caught the æsthetic craze, stop to consider this point. Cut flowers are lovely, and their beauties and uses are appreciated, but the individual plant, its marked individuality setting it apart for special places, uses, and occasions, has not been enough considered.

But I would rather you *grow* plants and help create their beauty, than merely enjoy the effect produced by another's efforts. This is not beyond your ability, but success in this is no more an accident than in any other department of science. The more knowledge you bring to your task, the more satisfactory will be the result of your labors. Apply your knowledge with patience. Let occasional failure stimulate, not discourage you. So will you gain a florist's best capital—*experience*. Experimental philosophy for me!

The beginnings of this science are so much more interesting than the beginnings of most. No endless practice of straight lines before you can produce a thing of beauty; no wearisome crawling up countless scales before you can produce sweet harmonies; no tedious technicalities to wade through, no dry dates to master, before you can get at the heart of your subject! Take your botany and some good work on gardening, if you are creditably anxious for exact information, but you will find it all delightful; your living illustrations will put life into every word and phrase in your text-books, and be a constant commentary on the subject-matter of your learned treatises.

Your imagination and reasoning powers as well as patience and perseverance, will be cultivated in your search after knowledge in this direction. Until you have tried, bright-minded girls, you do not know how far this fascinating quest will take you, nor in how many directions it will invite your eager steps. It has been said "A beautiful woman is a liberal educator." Beautiful flowers might almost be called her rivals. Did not the great poet say, as he took a little flower, "root and all," in his hand, "Little flower, but if I could understand what you are, root and all, all in all, I should know what God and man is!"

Suppose some one of you spends your leisure in studying the laws of plant-life (at least, so far as Mother Nature will let you into the beautiful secret); see if you will not soon say, "For me the humblest flower that blows, holds thoughts that lie too deep for tears!" and see if, when the happy Easter season returns, you are not able to express such thoughts in harmonies of form and color as you never could before!

EDITORS.

JOHN PHIN. FRED. T. HODGSON.

Published by

THE INDUSTRIAL PUBLICATION CO.,
49 Maiden Lane, New York.

The extraordinary demand which has been made for the "Amateur's Handbook," during the past few weeks, has entirely exhausted the second edition. We will go to press with a new edition in a few days.

Will those of our subscribers who receive two copies of the YOUNG SCIENTIST, kindly hand the duplicate to some friend interested in such matters, and thus perhaps aid us in securing a new subscriber? Remember that every additional name enables us to improve the Journal, so that all have an interest in adding to the number of our subscribers.

It is not uncommon to hear boys and girls complain that they have no time to do this, that, or the other or to play. The very name of play or pleasure has a magical power. That name makes the most toilsome and laborious pastime a delight; while, if it was called work, it would become irksome and oppressive. Boys and girls should have play and enough of it; there is wisdom in proper recreation and diversion—they harden the muscles, expand the chest, and give that rosy hue to the face that betokens cheerfulness, strength, and a freedom from disease that the inactive youth can never enjoy. After a period of study, the young mind should rest, and a period of diversion and play should succeed. One of the drawbacks of our advanced civilization is the continual strain the youthful minds are put to, to fit them for positions they may never fill. To distort the mind by cramming at the expense of the body is unnatural, and can only end in exhanstion sooner or later. Give the boys and girls a sufficiency of good healthy play; let them romp in innocent gaiety. Give them healthy bodies, and true nobleness will surely follow.

We call the attention of our readers to the articles on amateur wood-carving now being published in the YOUNG SCIENTIST, and trust that many of them will be able to follow the instructions given, and profit by them. There is no reason why many of our young readers—boys and girls —may not be able to acquire sufficient expertness in wood-carving to make many things that would have a commercial value of considerable magnitude. In Cincinnati, Philadelphia, and other cities, many young people are engaged in carving ornamental match-stands, cigar-holders, watch-stands, ink-stands, pen-holders, and a hundred other similar articles that readily find a market, if they possess any artistic merit. In Switzerland, thousands of young people find constant and lucrative employment at this work the whole year round, and hundreds of thousands of dollars' worth of the finished work is yearly exported to this country, England, and France, and is known in the "notion trade" as "Swiss carvings." The workmen, or artists, as they should be styled, are allowed to follow their inclination as to the character of subjects they treat; some cut groups of animals, others ornamental caskets, work-boxes, paper-cutters, salad spoons and forks, while others cut the pieces from which still others build the chalets so commonly seen even in this country as parlor ornaments. The tools required for this work are not very expensive; and as a pleasing and useful amusement, the art of wood-carving stands at the head of the list, with

the bare exception, perhaps, of ornamental turning.

We are sure our readers will fully appreciate our efforts this month in placing into their hands so large an amount of new and excellent matter. We have endeavored to cover a wide field of amateur work with sound practical articles, contributed by actual working amateurs, who know of what they speak. The articles on "Saw-filing," "Boys' Book-Case," "Wood-Carving," "Overlay Work," "Amateur's Shooting Board," and "Painting on Silk and Satin," are all reliable articles from reliable sources; and the papers on "Cheap Boats," "Mud-Bows," and "Indian Clubs," are interesting, useful, and, in a measure, practical, while the article on "Casting in Plaster" will be appreciated by many who wish to possess a knowledge of this useful art. Students of natural history will find something new and suggestive in the papers on "Birds" and "Anemones," both of which are written by contributors who speak from observation. Doubtless many of our boy readers will feel interested in the article on "Baseball Bats," as it will give them an idea of how many bats are annually made, where they come from, and where they go to. The Girls' Department is also well filled this month with excellent material, and we particularly direct attention to the article on "Floriculture," which is contributed by a young lady who has had considerable successful experience in this beautiful art. The paper on astronomy for the month of April, prepared by Prof. Berlin H. Wright, cannot fail to interest the greater number of our readers. Prof. Wright possesses the happy knack of being able to make very difficult matters quite clear to youthful capacities, as is shown by the article in the present number, which, though dealing with a rather complicated subject, is made so plain that any ordinary mind may comprehend it. Our illustrations, also, this month, are deserving of more than a passing notice, as the most of them possess a lasting value. Those on Wood-Carving, Overlay, Boys' Book-Case, etc., etc., are purely practical cuts, that may be brought into profitable use at any time, and almost in any place. Taking it altogether, our readers and ourselves have no need to feel ashamed of the present number, and we do not think we are asking too much of our subscribers when we ask them to use their influence in extending our circulation. All have friends, and there can be no more friendly act than that of placing in the hands of another the means whereby he may add to his happiness, knowledge, and future welfare, events which must follow from a continuous reading of the Young Scientist. Every new name added to our list secures for the future a useful member of society, and increases our ability to make the paper still better.

In several offices in New York where architectural and engineering drafting is done, part of the working staff consists of young ladies, who, it seems, acquit themselves to the satisfaction of their employers. There are many cases, it seems to us, where young ladies might be profitably employed in this kind of work, and it does not require much previous experience or knowledge of the use of mathematical instruments to be able to copy drawings or take tracings, and a few months' practice at this work by an intelligent girl fits her for better efforts. In England and Scotland quite a number of girls are employed as draftswomen, and in nearly every case they have given satisfaction. In speaking of this subject a short time since, the London *Engineer* says "that some months ago Messrs. Chapman & Gurney, at Gateshead, determined to make the experiment of making use of female skill in their drafting department, and went to the expense of erecting a special building, so as to give the ladies accommodation quite separate and apart from that of the ordinary draftsmen. The new office is roomy, well ventilated, and decorated with flowers during the summer months, and is approached by a door so placed that the draftswomen need never meet or see the other employees of the firm. Up to the present time five ladies have had occupation, chiefly in tracing plans of steam

winches, boilers, etc., for the shops, and in finishing off drawings of machinery prepared by the draftsmen. The office hours are from 8.45 to 11.45 in the morning, and from 1.15 to 4.45 in the afternoon. So satisfied has the firm been with the result of the experiment that they are now making arrangements for the introduction of more ladies into their various departments." Young ladies are peculiarly adapted for this class of skilled labor, and we have seen excellent original work turned out by a young lady who had devoted several months to the practice and study of drafting.

The Heavens.

BY BERLIN H. WRIGHT.

THE PLANETS.—APRIL, 1883.

Venus and *Mars* are becoming closer companions in their lonely march through desolate regions, where but few stars are visible to the naked eye, and the objects visible with moderate telescopes are quite as rarely met with. Venus, at the beginning of the month, is directly below the λ in Aquarius—see the figure at the upper right-hand corner of the illustration, Fig. 1, which also shows the relative positions of Mars, Venus, the Moon, and principal stars of this region.

All of the stars down to the fifth magnitude, which are in that portion of the ecliptic allotted to the constellation Aquarius, are here charted, from which it will be seen that the λ in the northwest corner of the constellation is the only figure by which it may be readily identified. The region upon the east of the Equinoctial Colure or for a much greater distance eastward is still more barren of prominent stars or figures. It would be very convenient sometimes if a fine star existed at the point where the earth's path intersects the Equinoctial Colure or First Meridian of the Heavens (corresponding to the meridians of Washington or Greenwich upon the earth), and the equator of the heavens. But the best way of locating this point is by aid of the λ and the two second magnitude stars which form the E. side of the Great Square of Pegasus, which lie almost exactly on the Equinoctial Colure, at about the width of the Ecliptic (16°) above the point of intersection.

The bright star Fomalhaut lies directly in a line with Venus and the λ, at about three times their distance apart below.

Venus rises on the 10th at 4h. 3m. morn.; 20th, 3.51 morn., and 30th, 3.40 morn. Mars rises on the 10th at 4h. 34m. morn.; 20th, 4.13 morn., and 30th, 3.52 morn.

The Moon passes Venus on the 4th, being nearly 6° north, and she reaches Mars the next day, passing about the same distance north of him (see cut). Venus passes within less than one-half of a degree of the fourth magnitude star *Lambda Aquarii* on the morning of the 10th, being south of the star.

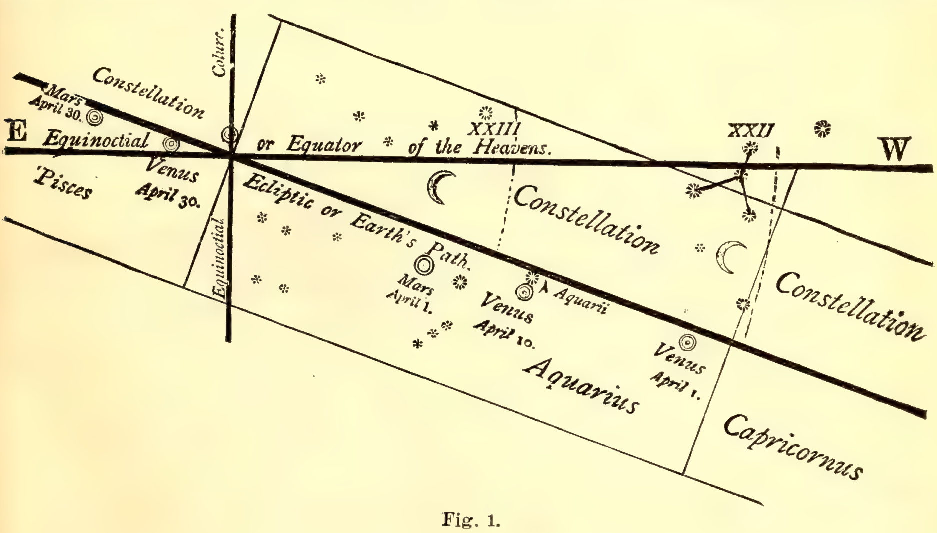

Fig. 1.

Jupiter sets on the 10th at 11.55 eve.; 20th, 11.23 eve.; 30th, 10.52 eve. He will be 4° north of the Moon on the 11th.

Saturn sets on the 10th at 9.18 eve.; 20th, 8.45 eve.; 30th, 8.11 eve. He will be less than 1° south of the Moon on the 9th.

Uranus passes the meridian on the 10th at 10.8 eve.; 20th, 9.28 eve., and 30th at 8.48 eve.

ECLIPSE OF THE MOON, APRIL 22.

The moon will be partially eclipsed on the morning of the 22d. This will be a very small eclipse, as only one-twelfth of the Moon's diameter enters the earth's shadow. The eclipse will not be visible east of the Mississippi Valley, the Moon setting before the eclipse begins. If the full moon should occur at the time the Moon is at her node, then a total eclipse of the Moon must occur, and the further from the node the Moon is at the time of full, provided it is not over 12° from the node, the smaller will be the eclipse.

As the Moon will be approaching her ascending node at the time of the eclipse, it will be apparent from the above diagram that the eclipse will be upon her upper or northern limb. At the next New Moon, or when the Moon is near

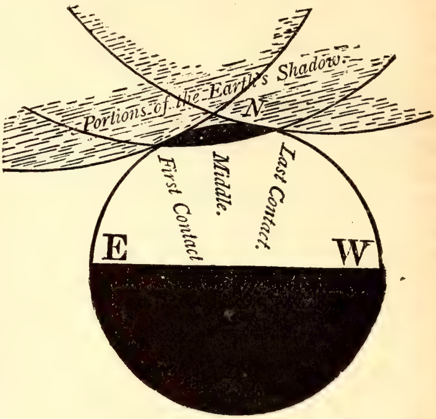

Fig. 3.

DIAGRAM OF THE ECLIPSE OF APRIL 22, 1883.

the descending node at *d* two weeks later, an eclipse of the Sun will occur, of which an account will be given in the YOUNG SCIENTIST.

The earth's shadow first touches the Moon at a point 33° from the north point towards the east, and the last contact occurs 4° from the north point towards the west.

As the Moon passes from west to east through the earth's shadow, the eclipse must begin upon the east side of the Moon.

The Moon will enter the earth's penumbra

Penn Yan, Yates Co., N. Y.

Current Notes.

—The much-ridiculed sunflower is thus praised by a writer in an English journal: "There would, indeed, appear to be but few purposes to which the sunflower cannot be turned with advantage to mankind. Scientifically dealt with, it will supply us alike with our morning roll and our evening cigar. It is equally susceptible of conversion into a cake of soap, surpassingly emollient, or into a rich and lustrous silk dress. As oil it may be consumed no less freely in the salad-bowl than in the table-lamp. Cattle will fatten sooner on sunflower-cake than upon linseed-cake. The little busy bee improves each shining hour more profitably in connection with the girasol than with any other opening flower. In fact, so numerous are its excellences and so beneficial its virtues that the sunflower may with great propriety be designated the friend of man."

—Pernicious stories of the "dime novel" class continue to do their mischievous work. The latest recorded victim was a New London boy, aged fourteen, who shot himself during a period of mental aberration caused by reading dime novels. Parents who hear of such cases and fear for their own boys usually wish that some one would kill the writers and publishers of the vile trash that most boys read when they can get it; but such wishes do not mend matters in the least, for there is no one to do the killing. The only antidote to the dime novel is good reading matter that is not prosy; there is plenty of it in the market, and fathers who do not see that their boys are well furnished with it have only themselves to blame if the youngsters are compelled to find their own literature for want of a paternal supply.—*N. Y. Herald.*

—The Mirage, or *Fata Morgana*, is a very curious but sufficiently common phenomenon, and in the Asiatic and African plains it is frequently observed. When the weather is calm and the ground hot, the Egyptian landscape appears like a lake, and the houses look like islands in the midst of a widely-spread expanse of water. This causes the *mirage*, which is the result of evaporation, while the different temperatures of the air-strata cause an unequal reflection and refraction of light, which give rise to the mirage. Travellers are frequently deceived, but the camels will not quicken their usual speed until they scent water. The Fata Morgana and the inverted images of ships seen at sea are not uncommon on European coasts. Between Sicily and Italy this effect is seen at the Sea of Reggio with fine effect. Palaces, towers, fertile plains, with cattle grazing on them, are seen, with many other terrestrial objects, upon the sea—the palaces of the Fairy Morgana. The inverted images of ships are frequently perceived, and many most extraordinary but perfectly authentic tales have been related concerning the reflection and refraction of persons and objects in the sky and on land, when no human beings nor any of the actual objects were within the range of vision.

Practical Hints.

Violet Stain for Wood.—The wood is treated in a bath made up with 4¼ ounces of olive oil, the same weight of soda ash, and 2½ pints of boiling water. It is then dyed with magenta, to which a corresponding quantity of tin crystals have been added.

Varnishing Paperhangings.—Give two coats of size, 1 lb. of pale glue in 1 gallon of water, should be used for oak and dark color, and when dry varnish with hard oak varnish. For varnishing marble, tiles, and other light papers, use gelatine size and white paper varnish.—*Furniture Gazette.*

Loose Screws.—It is a common thing, when a screw or staple becomes loose, to draw it out, plug up the hole or holes with wood, and then reinsert it. But screws and staples so secured soon come out again. It has been found that a much better way is to fill up the holes tightly with cork. Screws and iron so secured will remain perfectly tight, just as long as when put into new wood.—*Y. S.*

Blackboards.—For imparting a uniform black surface to boards that are to be used as blackboards take of shellac six ounces and of alcohol a pint and a half; warm the alcohol and digest the shellac in it until the latter is dissolved; strain the liquid through a cloth, filter it, and then introduce about five ounces of a mixture of boneblack and emery powder combined in equal parts, stirring the whole together until the ingredients are thoroughly incorporated; the mixture should have the consistency of very thin syrup. Thin, if necessary, with more alcohol, and apply two coats, using a soft, smooth-edged brush.

Metallic Designs on Glass.—An ingenious method of obtaining mirror-like designs on glass has been devised by Leclerc. The glass having been silvered by the chemical process, is coated with a thin and uniform layer of sensitive bitumen, and this is exposed under a transparency, the next step being to wash away the unaltered bitumen with oil of turpentine, so as to leave the bituminous design on the silvered glass. The application of moderately strong nitric acid removes the silver, excepting where it has been protected by the bitumen, so that the metallic design shows like a mirror from the reverse side of the glass. The plate may be backed by paint or any other suitable material.

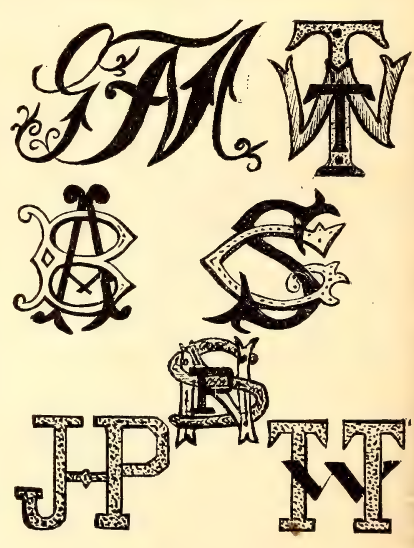
Black Oak.—To turn oak black, so as to cause it to resemble ebony, the wood should be immersed for forty-eight hours in a hot saturated solution of alum, and then brushed over several times with a logwood decoction, prepared as follows: Boil one part of best logwood with ten parts of water; filter through linen, and evaporate at a gentle heat until the volume is reduced one-half. To every quart of this add from ten to fifteen drops of a saturated solution of indigo, completely neutral. After applying this dye to the wood, rub the latter with a saturated and filtered solution of verdigris in hot concentrated acetic acid, and repeat the operation until a black of the desired intensity is obtained. To imitate rosewood, a concentrated solution of hypermanganate of potassa is spread on the surface of the wood and allowed to act until the desired shade is obtained. Five minutes suffice ordinarily to give a deep color. A few trials will indicate the proper proportions. The hypermanganate of potassa is decomposed by the vegetable fibres with the precipitation of brown peroxide of manganese, which the influence of the potassa, at the same time set free, fixes in a durable manner on the fibres. When the action is terminated, the wood is carefully washed with water, dried, and then oiled and polished in the usual manner. The effect produced by this process on several woods is remarkable. On the cherry, especially, it gives a beautiful red color.

Notes and Queries.

In continuing this department, which has been found of so much value, we would remind our readers who wish for information on any of the arts and sciences, that they are cordially invited to make their wants known through this column, and those of them who can furnish accurate answers to questions asked are requested to send in replies. Doubtless many of our subscribers may know of methods, processes, or devices that may be better or more suitable for the particular case in question than anything generally known, and it is this reason that induces us to keep this department open for a medium, where an interchange of ideas and practices may be made to the advantage of all our readers. Correspondents will please send their full address when forwarding their communications—either questions or answers—not for publication, unless expressly so stated, but so that we may know where to find the writer if desirable. Communications should be sent in on or before the first of each month previous to publication, to insure insertion in next issue.

Answers.

41. MONOGRAMS, G. F. M., A. B., and G. S.—We have received monograms of these initials from several sources. A number of them came too



late for this issue, and others did not possess sufficient merit for publication. We are pleased to find so many young people take an interest in

this matter who have ability to place on paper their ideas of what combinations of letters ought to be. It is impossible to publish everything sent to us, but we hope our young readers will not feel aggrieved if they do not see the result of their efforts appear. It is not because we do not appreciate their efforts that they do not appear in print, but simply because we have not space at our command to accommodate all that is sent us. This, however, should not discourage our young people from sending in their contributions, as everything sent us is a clear gain to them in practice and experience, and by continually "pegging" away, they will be sure to accomplish something before a great while that will compel us to recognize their efforts. The illustration shows the monograms sent.

The monograms J. H. P., T. W. T., and N. S. P., were sent us too late for the March number, and are in compliance to requests made in February YOUNG SCIENTIST.

42. INLAID MONOGRAM.—I herewith send you a design for an inlaid monogram, for E. B.'s consideration. I think it fully complies with the conditions of his request. It may be cut with either a Challenge, Dexter, or a Barnes scroll-saw. I would suggest that the background of the inlay or body of the box be made of walnut, and the inlay of rock-maple; or the box might be made of rock-maple, and the inlay of amaranth or mahogany. If ebony is used for the body of the box, the inlay should be of ivory, which may

be very easily cut, if care is taken while sawing to not feed too rapidly. A mahogany background would look very well with brass inlay, which is almost as easily cut as ivory. If E. B. can afford it, however, I would advise him to get fine rosewood for the body of his box, and inlay it with silver. The rosewood may be veneer, glued on a pine or whitewood base; then the silver need be no thicker than the veneering. I shall be pleased to give E. B. any further information I possess on this subject, if he desires it.—BOSTONIAN.

43. OVERLAY DESIGNS.—"Bostonian" sends us six designs for overlay work for panels, etc., which we publish on page 108 of the present issue, along with description and instructions for making.

44. COLOR LANGUAGE.—(1) Properly speaking, there is no color language. Colors are simply considered as expressions of sentiment when used for that purpose, and are defined as follows: Blue means love: Violet, friendship; a bouquet of violets, therefore, if received from a lady, means that no love is to be expected, but friendship only. Red means ambition; Indigo Blue, the spirit of rivalry; Green, the love of change—fickleness; receiving a love-letter on pale green paper, or sealed with a green wafer or sealing-wax, means that the love-match is to be broken off. Yellow is the color of paternity and maternity, under the pretext that it is the yellow ray of the spectrum which causes germs to develop. So much for the colors of the spectrum. In regard to other colors, black means favoritism; White, unity—universality; Gray, power; Silver Gray or Bluish Gray, feeble love; Lilac or Lavender, feeble friendship; Brown, prudery; Pink, modesty; Pale Pink, false shame. (2) The type-writer is a machine for printing with movable type. The first patent in the United States for a practical machine of the kind was issued in 1868. The types were arranged in parallel rows, and the impression given by the striker or plunger, the operator having but to depress keys arranged with reference to rapidity of motion in the necessary order. In other type-writers the printing types are placed on the periphery of a wheel, and brought to the printing point by revolution. In most varieties the types are at the end of levers, so arranged as to strike at a common printing point, and the paper is passed under that point by ordinary clockwork machinery.

45. PAINTING ON SATIN.—We refer you to an article on this subject in the present number, on page 119. We are indebted to the *Art Interchange* for this paper, which we think is almost exhaustive on this question.

46. REVENUE MARINE SERVICE.—To obtain an appointment as a cadet in the Revenue Marine Service candidates are obliged to undergo a severe examination. The candidate's age must be between eighteen and twenty-five years, and no person will be appointed under any circumstances whose age is not within these limits. He must furnish satisfactory evidence that he is of good moral character, and of sober and correct habits. He is then required to pass an examination as to his physical qualifications, which is made by a board of medical officers from the Marine Hospital Service, who are designated by the Secretary of the Treasury. If the candidate is found to be of vigorous constitution, physically sound, and not less than five feet in stature, he is subjected to a written examination in reading, writing, spelling, arithmetic, algebra, geography, history and grammar, before a board of officers also designated by the Secretary of the Treasury. A standard of proficiency is fixed by this board, and if the candidate falls below this standard, he will be rejected. He will be allowed, however, a second examination at the next annual convening of the Board of Examiners, and if he fails in this examination also, his rejection will be final. Candidates who attain the required standard in both the physical and mental examinations will be eligible for appointment, and will be placed upon a list in the order of proficiency exhibited in their examination. From this list names will be taken in regular order for appointments to fill existing vacancies, such as may occur before the class for the year is made up. Passing the required examination does not guarantee a candidate's appointment, however, as the list is not likely to be exhausted in making up the class. In the physical examination special attention is given to the visual powers of the candidate, and more particularly to color-blindness and the defects in acuteness of vision. The academical examination is in arithmetic, in notation and numeration, compound numbers, properties of numbers, fractions, ratio and proportion, percentage, interest, discount, mensuration and evolution; in algebra, to equations of the second degree; the whole English grammar; the history of the United States; a theme upon given subjects as a test of penmanship and composition; a written exercise in spelling, and a general acquaintance with the geography of the world.

47. HUMAN BONES.—According to Brande there are 260 distinct bones in the human skeleton, counting everything. An excellent authority—Willard Parker—in Johnson's Cyclopedia, says: "The entire skeleton of the adult consists of 204 distinct bones; if the teeth and certain accessory bones, termed sessamoid, are included, the number is 246." The difference in these statements rests in the fact that what some persons term bones, others do not. It is generally understood,

however, that there are 246 distinct bones in the human body.

48. POTTERY.—In reply to "Quiner," we may say that it is impossible to do this subject justice in this department, and the best we can do is to give a few hints and recipes here, and a promise that the subject shall receive our attention at length in future numbers. Should the following be found useful to "Quiner," we may return to the subject again here:

In enamelling articles of pottery and glass, the colors are prepared principally from the oxides of different metals melted with a vitreous flux, well ground for use in an essential oil, and in enamel painting laid on with a camel-hair pencil, the fire of the enamel kiln fusing the colors so that they adhere to the glaze. The principal colors are oxides of lead, platinum, chromium, uranium, etc., etc. Oxides of tin and antimony give opacity.

Manuscript books of recipes are very imperfect. Managers of works having had no scientific education, are not to be trusted when dealing with this branch of pottery.

Of "dips," something useful may be found in the following:

Purple Dip.—40 quarts of blue clay slip, 1 oz. calx blue, well ground, 2 ozs. manganese.

Blue Dip.—50 quarts blue clay slip. 1 oz. calx blue.

Red Sponge Dip.—4 quarts red slip, 2 quarts white slip, 1 lb. steel filings, 1 lb. lead ore.

Green Dip.—5 quarts cane slip, 5 ozs. ground zaffre, 1 oz. copper scales.

Another.—1 quart blue clay slip, 1½ oz. ground nickel.

White Dip.—6 quarts blue clay slip, 1 lb. steel filings, 1 lb. lead ore.

Olive Green Dip.—12 quarts cane slip, ½ oz. zaffre, well ground, 2 ozs. copper scales.

Olive Dip.—1 quart black marl slip, 2 quarts blue clay slip, 2 ozs. zaffre.

Another Blue Dip, said to be "very good."—4 lbs. Cornwall stone, 1 lb. Cornwall clay, 3 pints bone slip, 3 pints blue clay slip, 10 ozs. cobalt blue. Fluxed liquid.

Flux for Blue Edging, etc.—4 lbs. flint glass, 1 of blue calx, 2 ozs. nitre, 2 ozs. borax.

Queries.

49. IDA, Phila., Pa.—If Miss H., or some other well-informed person, will give a few hints on the cultivation of parlor plants, and describe what plants are the best to nurture, a great kindness will be conferred on a life-long invalid.

50. KATIE B., Rochester, N. Y.—I am in want of a recipe for cleaning kid gloves, one that has been tried by some of your "girl" readers who have been successful. I do not want any of the methods that are written in some of the cheap receipt books, as I have never been able to make a success of the work by doing it according as it is described in those books. What I want is a real practical, common-sense process, that any girl of fifteen can follow. Now, girls, which of you is going to send the best recipe?

51. BIG BOY, Utica, N. Y.—Having tried my hand on amateur woodwork, with pretty satisfactory results—at least my friends say my work is nearly as good as if done by a professional—it is now in order for me to attempt the operation of staining, varnishing, and polishing; and as many other "Big Boys" besides myself may wish to acquire some knowledge of the processes, I make bold to ask you to publish a few recipes for this kind of work, and oblige an earnest student.

52. AMATEUR, Newark, N. J.—I have a small grindstone that has been in use quite a long time and is worn away much more at one point than at others, and in consequence I find it very troublesome in grinding my tools, when such operation is necessary. Can you or any brother reader tell me if this trouble can be removed, or will I have to purchase a new stone?

53. MONOGRAMS.—The requests this month for monograms are more numerous than for previous months, and we fear we shall not be able to afford space for illustrating more than about one-quarter of them. The following are some of the combinations asked for: E. S. G., plain; T. M. G., rustic; L. L. L., ornamental; A. L. L., neat and plain; A. C., no directions; A. T., V. A., and C. H. We have a number of other combinations asked for, but we cannot find space for more than those mentioned above.

54. MONOGRAMS.—Bella S., Detroit, asks "why we do not publish some monograms suitable for embroidery work, such as are used for the corners of napkins, handkerchiefs, and similar articles?" Well, Miss Bella, we shall be pleased to publish any suitable designs that we may receive for the purpose, and hope some of our lady readers will take the matter up, and furnish us with a number of designs for needlework.

55. NELLIE D., Denver, Col.—Last summer I was East, and saw quite a number of needle-cases made by using two shells, some fine flannel and ribbon. I have a number of shells, and shall be pleased to have some information as to the manner of making the cases, if some of your lady readers will kindly impart it.

56. H. A. K., Kansas.—How can I make a small electric light apparatus? What do you think of the new portable electric light made in Boston? Is it a good thing?

NOTE.—It is rather difficult to make a small electric light apparatus that is good for anything. The Grove or Bunsen battery, about 30 cells, would probably be the most convenient. It was this form that was used by scientific lecturers before the days of the dynamo apparatus. We have not seen the Boston light, and cannot express an opinion, but as we understand it, it is used chiefly for lighting gas, not for giving a light. You will notice that the advertisement reads, "Portable Electric Lighter."

Market Report.

Retail Prices.

IMPORTED CAGE BIRDS.

Canaries, *Belgian*, per pair	$6.00 to 15.00
" *French*, each	6.00 to 15.00
" *German, Hartz Mts.*, each	2.50 to 10.00
Gold Finches, each	1.50
Gold Finch (mules), each	2.50 to 5.00
Bull Finches, each	2.50
Bull Finches (tuned), each	10.00 to 40.00
African Finches, per pair	2.50 to 5.00
Chaffinches, each	1.50
Linnets, each	1.50 to 2.00
Linnets (mules), each	2.50 to 5.00
Green Linnets, each	1.50
Java Sparrows (blue), each	1.50
Java Sparrows (white), per pair	4.00 to 6.00
English Sparrows, per pair	1.00
Siskins, each	1.00
Gray Cardinal, each	4.00 to 5.00
Nightingales, each	8.00 to 25.00
Japanese Nightingales, each	5.00 to 10.00
Thrushes, each	5.00
Skylarks, each	5.00
Troopials, each	7.00 to 12.00
European blackbirds, each	5.00
Black-caps, each	4.00
Starlings, each	4.00 to 6.00
Ring Doves, each	2.50 to 3.00

AMERICAN CAGE BIRDS.

Canaries, each	2.50
Mocking Birds, females, each	1.00
" " singers	12.00
Robins	2.50 to 5.00
Blue Birds ("Blue Robins") each	1.50 to 2.00
Indigo Birds, each	1.00
Nonpariel, each	1.50 to 2.00
Virginia Cardinal, each	3.00
Bobolinks, each	1.50 to 2.00
Yellow Birds, each	1.50 to 2.00

QUADRUPEDS.

Terriers, *black and tan*, each	5.00 to 30 00
Terriers, *Scotch and Skye*, each	5.00 to 30.00
Newfoundland Pups, each	10.00 to 15.00
Pomeranian or Spitz "	5.00 to 15.00
Greyhounds, *English*, "	10.00 to 25.00
Greyounds, *Italian*, "	10.00 to 30.00
Guinea-Pigs, *common*, per pair	1.50
" " " " large	1.50 to 3.00
Guinea-Pigs, *all white*, "	2.00 to 4.00
Squirrels, *gray*, "	5.00
Squirrels, *all white* "	15.00 to 25.00
Squirrels, *flying* "	3.00 to 4.00
Squirrels, *small red* "	2.00
Rabbits, *common*, per pair	1.00 to 2.50
Rabbits, *fancy breed*, according to age and purity of breed, per pair	3.00 to 15.00
Ferrets, *English*, "	15.00
Raccoons, each	4.00 to 5.00
Cats, *Maltese* (males), each	5.00
" " (females), each	3.00
Cats, *Albinos, pink or blue eyes*, each	3.00 to 5.00
Rats, *white China, pink eyes*, per pair	1.50
Rats, *piebald*, per pair	1.50
Mice, *white, pink eyes*, per pair	0.50
Mice, *piebald*, per pair	0.50

Prices Paid for Pet Stock by Dealers.

Guinea-Pigs, per pair	$0.40 to 0.75
Squirrels, *gray*, each	0.50 to 1.00
Squirrels, *flying*, per pair	0.25 to 0.50
White mice, per pair	0.15 to 0.20

MARINE AQUARIA STOCK.

Fringed Sea Anemone, Medium-sized specimens	1.50
White-Armed Anemone	0.50
Small Orange "	0.10
Buccinum Snails, per dozen	0.25
Small Crabs, each	0.25
Silver Shrimp, each	0.10
Small Hermit Crabs, each	0.15
Small Spider Crabs (decorating)	0.15
Barnacles, each	0.15
Sheepshead Lebia	0.25
Killie " "	0 10
Eels, "	0.10
Serpulæ, per mass	0.75
Edible Mussels, per mass	0.25
Mussels, edible, per mass	0.25
Sea Cucumbers	1.00
Sertularia	0.25 to 0.50

ALGÆ "SEA-WEEDS."

Ulva, per mass	0.25 to 0.50
Solaria, "	0.25 to 0.50

FRESH WATER AQUARIA STOCK.

FRESH-WATER STOCK.

Stickle Backs, Nest-building, per pair 0.30

Plants, per bunch	0.15	Small Turtles, per pair.	0.25
Shells, per quart	0.50	Snails, per dozen	0.20
Small Dip-Nets	0.50	Frogs, each	0.25
Aquaria Cement 1lb. box	0.30	Fresh-Water Mussels	0.10

Valisneria Spiralis, per bunch	0.25	For the Microscope and Fresh Water Aquarium.
Nitella-Flexilis, "	0.25	
Anacharis, "	0.25	
Ball Plant (Utricularia)	0.25	

Small Rock-Fish, Sun-Fish, Dace, Cat-Fish, Tadpoles, Eels, Lizards, each 0.10

Gold-Fish	0.25	These are all varieties of the golden carp or gold-fish.
Pearl-Fish	0.25	
Silver-Fish	0 25	
Japanese King-gio	2.00	

SEMI-AQUATIC PLANTS FOR ORNAMENTATION OF PONDS, LAKES, AQUARIA AND FOUNTAINS.

White Water-Lily, per root	0.25
Yellow " "	0.25
Arrowhead Lily, 6 bulbs	0.25
Pitcher-Plants, per root	0.25
Fresh-Water Cattails, per root	0.25
Giant Rush " "	0.25
Floating Heart (Limnantheum), per root	0.25
Calamus (sweet-flag), per root	0.25
Water-Cress, cuttings	0.25
Jack-in-the-Pulpit, 6 bulbs	0.25
Lobelia Cardinalis	0.25
Large, Showy Blue Lobelia	0.25
Water Violet (very curious)	0.25

Prices Paid by Dealers.

At this season of the year all stock for aquaria brings a high price.

Aquarium fish (*now scarce*) per hundred	1.50 to 2.00
Gold Fish (*now scarce*) per hundred	8.00 to 10.00
Aquarium Plants (*now scarce*) per hundred bunches	5.00

SHELLS.

Collections of small "cabinet" shells for schools, private cabinets, range from $5.00 to $50.00.

Mother-of-pearl shells, for painting, 75 cts. to $1.50.

Single specimens of cabinet shells range from 25 cts. each to $3.00.

Masses of corals, 50 cts. to $3.00.

Green snail and cowry, with the Lord's Prayer engraved on them, 50 cts. to $2.50 each.

Conch shells, for mantels or hearthstone ornaments: West India Conch, 25 cts.; East India Yellow Helmet, $1.00 to $2.50; Bahama Black Helmet, 50 cts. to $1.50; Bahama Hatchet Helmet, 50 cts. to $1.25. These shells are also for cameo engraving. Zanzibar Cameo, 25 cts. to $1.00.

Ground and polished shells: New Zealand Green Ear, 50 to 75 cts.; New Zealand White Ear, 50 to 75 cts.; Japan Black Ear, 50 cts. to $1.00; California Red Ear, 75 cts. to $1.25.

Fine shells for fancy work, according to colors and variety, per quart, $1.00 and up.

Fancy Wood for Scroll Sawing.

The prices given for the various woods used in this work are for the best of qualities of seasoned material, planed on both sides, ready for immediate use. They can be furnished in quantities to suit purchasers. Prices are by the square foot, and vary according to thickness of material.

For all information on this subject, as to reliable dealers, etc., etc., send postal card to YOUNG SCIENTIST, When desired, the goods can be sent through this office, but in all cases remittances must accompany the order.

EXCHANGES.

Only those who are *yearly* subscribers, and whose names are entered on our books have the privilege of inserting exchanges.

Exchanges must be on separate slips of paper or postal cards. If mixed with business matter in letters or cards they are filed away and never reach the printer.

Exchanges must not exceed thirty words.

Buying and selling belong to the advertising department.

We reserve the right to omit the exchange column, when we have not room for it, and the amount of space at our disposal will regulate the number of insertions given to each *exchange*, the preference being always given to those who have not previously used our columns.

"Crystallography" (40c.); "Electricity" (40c.); "Selection and Use of Microscope," abridged, (30c.) Either in exchange for "Workshop Companion," or two for "The Microscope," by Ross, or offers. C. H. Denniston, Pulteney, N. Y.

A printing-press, chase 5½ by 7 inches, in good order; will exchange for a large self-inking press or type. A. W. Barrett, Canajoharie, N. Y.

Home Medical Battery, cost $7; Lemair's Field-Glass, No. 2202 of Queen's Catalogue, cost $15.50; Achromatic Spy-Glass, power 25 times. To exchange for books or offers. Emerson Heilman, Heilmandale, Pa.

Silver watch, key-winder and Home Works, for good microscope or offers. Wm. Hodgson, 128 Mangin St., New York City.

A small collection of coleoptera, comprising 100 species and 300 specimens, all correctly named, in exchange for bird-skins, insects, books, or eggs. Emil Laurent, 621 Marshall St., Phila., Pa.

A small magic lantern, Ruby pattern, with twelve slides, for a good book on Entomology, with illustrations. Willie R. Hotchkiss, Morrisdale Mines, Clearfield Co., Pa.

Wanted, Thompson's "Witchery of Archery." Must be in good condition. Write before you send. J. Anthony, Jr., Coleta, Whiteside Co., Illinois.

A telescope worth $3.50, for a self-inking printing-press and outfit; chase not less than 2½ by 3½ in. Eddie Judd, 260 Connecticut St., Buffalo, N.Y.

To exchange for offers: $20 scroll-saw, Seneca Falls make, $4 Bailey circular plane, set of Auburn metallic planes, brass-bound four-foot rule, fourfold, Traut's patent combined plow, dado, etc., cost $7. F. A. Rappleye, P.O. Box 12, Farmer Village, Seneca Co., N.Y.

Bee Hive wanted; one of the old-fashioned straw "skeps"; say what you would like in exchange. Apis, care of Young Scientist, 49 Maiden Lane, N. Y.

A first-class type writer, in excellent condition, cost $125.00, to exchange for good microscope, telescope, or valuable scientific books; send full particulars. A. B., Box 114, Lewiston, Maine.

A $30 stencil outfit (Spencer's) for a self-inking printing press in good condition, chase about 6 x 9; rich ores and minerals of Idaho for scientific and instructive books, printing press, type, etc. J. P. Clough, Junction, Lemhi Co., Idaho.

Wanted pyrites of iron from Colorado gold mines in exchange for sea shells and other gems; send list of what you have to exchange. S. Ferguson, Eureka Springs, Arkansas.

Scientific specimens of various kinds for same. Geo. E. Frazier, Caldwell, Ohio.

A banjo in good condition, two pairs of rosewood bones, three splendid games, and a fine set of drawing instruments, for a good cornet, viola, violincello or double bass. L. B. Hill, Kalamazoo, Mich.

Lester W. Mann, Randolph, Mass., Box 162, has Demas scroll saw, lathe and tools, emery wheel; $20 worth patterns; Smithograph; large harmonica, cost $1.75; novelties in seeds; for large self-inking press or offers.

10 volumes Chambers' Encyclopædia, American Book Exchange edition (cloth); Bonanza printing press, chase 3 x 5, card type, ink roller; spyglass, power 10 times; for French triplet, 1-5 in., or offers. H. P. Nichols, P. O. Address, Bridgeport, Conn.

A good telescope, also foot-lathe and saw combined, each worth $10.00, for shells, fossils or relics. Independent, Conncautville, Crawford Co., Pa.

Birds' eggs to exchange for others; send list of what you have to exchange. Emil Laurent, 621 Marshall St., Philadelphia, Pa.

Twelve or fifteen volumes of the American Agriculturist to exchange for scientific books or offers. W. H. Osborne, Chardon, Ohio.

J. D. Rice, P. O. Box 473, Trenton, N. J., would be pleased to correspond with mineralogists for the purpose of exchanging specimens and ideas.

To exchange, my collection of nearly half a thousand rare postage stamps with catalogue, for second-hand Flobert rifle; must be in good condition. H. E. Whitman, Station M, New York.

I have a large assortment of foreign stamps to exchange, also Confederate money. Collectors send sheet and I will return it with mine. Box No. 2, Coeymans, N. Y.

Electric bell engine, cost $15; pair of analytical scales, cost $10; pair of Bell Telephones to exchange for a printing press, watch or offers. Geo. N. Bigelow, Box 754, Palmyra, N. Y.

Any person wishing to trade bird's eggs may apply to me and I will send them my list of bird's eggs. I have only a few at present, but am receiving a number every month. A. G. G., Box 26, Summit, New Jersey.

Minerals of Idaho for Standard Works on the Horse—Wallace's Registers and turf journals. Wanted, also other useful books, bound and in good condition. Many varieties named in my list. J. P. Clough, Junction Lemhi Co., Idaho.

To exchange for offers first four (fifth when completed) bound volumes of YOUNG SCIENTIST. J. N. Brooks, P.O. 1468, N. Y. City.

Wanted engraver's tools with book of instructions, for a Victor Press, with cabinet, 2 type cases, type, ink roller and furniture complete; perfectly new. L. Warren, 72 Cumberland St., Brooklyn, N. Y.

A Fletcher Foot-Blower, cost $5, as good as new; will exchange for a Cushman, 2 in. or up scroll chuck, or other make; will give a satisfactory trade on the difference in price, if any. Louis Lutz, St. Clair Street, Toledo, O.

I have a lot of "Galaxy" (magazines) which I would like to exchange for an air rifle in good condition, a collection of birds' eggs, or offers. W. B. Greenleaf, 480 La Salle Ave., Chicago, Ill.

I have a Mechanical Telegraph with book of instructions, books, etc., which I wish to exchange for good microscopical objects, mounted on 3 x 1 slips. Address, with list, J. H. Frey, Millersburg, Ohio.

To exchange, "How to Use Microscope," Wells' "Natural Philosophy," and many other books, chemical apparatus, etc., for good photographic camera, and lenses. W. H. Weed, 254 Putnam Ave., Brooklyn, N. Y.

Wanted "Quimby's New Bee Keeping," for "Our Own Birds of the United States," by W. S. Baily; new. Joseph Anthony, Jr., Colota, Whiteside Co., Ill.

Wanted a good book in anatomy, in exchange for a book on chemistry, or for story books. A. G. G., Box 26, Summit, New Jersey.

A German-silver trimmed, patent lined, cocoa flute, cost $4, in good order, for good spy-glass, photo-material, or offers. Ewing McLean, Greencastle, Ind.

I have some fossil shells from the west bank of the Mississippi, to exchange for Indian relics. A. W. S., 187 E. 71st St., N. Y.

I have a magic lantern, Ruby pattern, nearly new, and 5 views; also "Our First Century," bound in leather, cost $7; state what is wanted in exchange. I. N. Spencer, Box. 217, So. Manchester, Conn.

First-class telegraph instrument and attachments, and "Wood's Botany," for bound volumes of periodicals, books, or offers. H. P. Albert, Anderson, Iowa.

Wanted a book on treatment and care of canary, also breeding of same; will give in exchange book named "Market Garden, Flower Garden and Bees," or 40 "Scientific Americans" or "Seaside Libraries;" want also old books. M. J. Mulvihill, Norwalk, Conn.

The Young Scientist

SCIENCE IS KNOWLEDGE. KNOWLEDGE IS POWER.

A PRACTICAL JOURNAL OF

HOME ARTS.

VOL. VI. NEW YORK, MAY, 1883. No. 5.

Amateur Wood-Carving. (*Continued*).

BY LEO PARSLEY.

IN treating the sunflower shown in Fig. 1, I have strictly adhered to the conventional style, which in cases of this kind is perhaps the most effective; the leaves and flowers are treated alike; they are, however, reduced in size, as space here is limited, but they can easily be enlarged by the amateur to either twice or three times the size, if desired.

The method of working to be adopted with this design is exactly the same as that described in my last paper for carving the ivy scroll panel. In carving fretwork, picture-frames or brackets, the same treatment is to be used, but in finishing off, it will be, in many cases, advisable to chamfer the edges of the leaves, etc., from the back, so as to take away

Fig. 1.—PANEL SUNFLOWER, CONVENTIONALLY TREATED.

the appearance of heaviness, which invariably results when the thick edges of leaves or flowers are left.

I noticed in the YOUNG SCIENTIST for January an interesting article on walking-sticks; and in case any of the readers

of this paper may feel inclined to make walking-sticks for themselves, I have given two grotesque designs, which may be carved on the heads of either walking-sticks or umbrellas. Fig. 2 is a suitable design for an ordinary knob, and Fig. 3 will suit a half-crutch admirably. If the reader does not care to go to the trouble of preparing a cane, he can easily buy one that will suit his purpose at a cheap rate. In carving heads or similar objects on sticks, it is always better to rely entirely on the grotesque for designs; and it will be an agreeable surprise to the amateur to find how easily these grotesque heads can be cut on a stick.

Fig. 2.—GROTESQUE DESIGN FOR KNOB OF WALKING-CANE.

The principal thing to avoid is all sharp points, which are liable either to hurt the hand or tear the glove; and the design should in every case be adapted to the size and shape of the knob. In carving these heads a vise or bench-screw of some kind will be required to hold the work firmly whilst being operated upon, and then the same process is gone through as with all other descriptions of carvings; first of all, draw roughly the design on the knob, then block out, and finally finish off the work, adding any fancy touches that may be deemed advisable to give effect to the design. It is a frequent practice with carvers to roughly model the design in clay before commencing to carve it in the wood, or if clay is not at hand, to chop in roughly the design in a piece of soft wood, so as to see the effect the design will really have in the wood when worked out.

In finishing off the work, outlines frequently have to be rectified, and alterations made, that are not noticed as being defective when the work is blocked out. When setting in the outlines of a panel, for instance, it is better to avoid cutting in too deeply, otherwise the groundwork presents a surface defaced with tool marks after the outlines have been corrected, and it is not always easy to efface these marks, even when the ground is punched. In shaping a design, however, it is a good

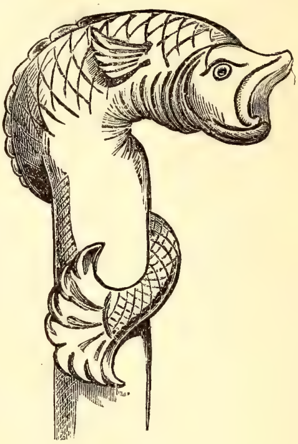

Fig. 3.—GROTESQUE DESIGN FOR HALF-CRUTCH WALKING-CANE.

plan to use the tools boldly and cut clean; instead of which, many beginners will make a dozen cuts where one would suffice.

Before closing these papers I will give designs and instructions for delicate carving in ebony, and will also give directions and designs for the now almost universal incised work.

Poisonous Plants.

BY A. W. ROBERTS.

POISON ivy, poison oak, poison mercury vine, poison swamp sumac, poison dogwood, and poison elder!

Are these not terrible names and villainous reputations to give to two of the most beautiful inhabitants of our woods, meadows and hedges? But though no one would suspect this poison ivy, oak or mercury vine, as it is called, that climbs up leafless tree-trunks, unsightly stone walls, rocks or fence-posts, of containing within its cheerful bright green

leaves such cruel and villainous qualities, nevertheless thousands of grown-up people and children have suffered intense pain and disfigurement by a very slight contact with it and even by standing in its presence.

This wretched vine prospers wherever it can obtain a foot of ground, let it be sandy, stony, moist or parched; contented and prosperous, it reaches forth

Fig. 1.—POISON IVY, SHOWING BERRIES OR FRUIT, AND ÆRIAL ROOTLETS.

its poisonous arms. Its scientific name is *Rhus toxicodendron.* "Climbing by rootlets over rocks, etc., or ascending trees, leaves with three leaflets, which are rhombic-ovate, mostly pointed, and rather downy beneath, variously notched or cut, lobed or entire" (Gray). And by habit it is essentially a climber, though when growing without support it becomes erect, robust and bushlike. Under these conditions it is commonly known as the poison oak, and was long considered by botanists as being a separate variety of the Rhus genus. The stem of the vine is almost smooth, except where the aerial rootlets or tendrils are attached to the under portion and sides of the stem. These tendrils are of a bright brown color when young, and of a dingy gray when old. The masses of fruit or seed vessels, when young, are of a light green color, but turn to an ashen gray when

Fig. 2.—LEAF OF POISON IVY (about half the actual size).

fully ripened. The leaf is smooth, and inclined to be shiny, curving downward from the midrib.

One would consider the poison ivy sufficient for all evil, but he has a relation, a very close relation, compared with which he is nowhere, and who is commonly known as the poison sumac, poison dogwood, poison swamp sumac, and poison elder, and by botanists as the *Rhus venenata.* "The branches are smooth, or nearly so, leaves odd-pinnate, leaflets 7-13, abovate-oblong, somewhat pointed at both ends, entire" (Gray). This fiend of our beautiful wild flora is ten times more severe in its poisonous qualities than the ivy. It flourishes and delights to dwell in meadows and on the margins of woodland streams. Unlike the poison ivy, which climbs and clings to everything, the poison sumac grows erect, often attaining

stately proportions—a height of twenty feet—but more commonly the proportions of a shrub or small tree. The leaves are smooth and nearly hairless, and resemble those of the hickory or Wistaria, but are much smaller. The bark is smooth; the

Fig. 3.—POISON SUMAC, SHOWING LEAF AND BERRIES.

fruit is contained in long, drooping and very shiny black or dark brown stems, and in general appearance closely resembles that of the poison ivy. In the fall of the year the leaves take on beautiful tints of red and yellow, and are often gathered by leaf collectors for household adornment. On one occasion three ladies having gathered bunches of these leaves, held them close to their faces, as a protection from the sun; all three became so severely poisoned as to be confined to their beds for six weeks. The berries, too, are often gathered for the same purpose, and numerous instances are known of people having been poisoned by sleeping in rooms containing ornaments composed of these berries. The other day I met a collector for fresh-water aquaria, one who has tramped the woods, marshes and streams for twenty years, strong, robust, and abstemious in his habits. He had always handled the poisonous ivy and sumac with impunity, but at last he got a terrible dose of sumac poison, which sent him to bed and in the doctor's hands for over a month. It must have been that his system had undergone some change which placed him in a condition to become severely poisoned. Some years ago I contributed the following experience to a contemporary journal. It was at that time the fashion to wear large wreaths and bunches of artificial flowers inside and outside of ladies' bonnets. The flower-makers being hard pressed for material, made use of dried grasses, seed vessels, burrs and catkins. These were painted, dyed, bronzed and frosted, to make them attractive. I became greatly interested in the business and the ingenuity displayed, and spent much time in examining the contents of the milliners' windows. On one occasion, when standing before a very fashionable milliner's window on Fourteenth street, I was horrorstricken on discovering that an immense wreath of grayish berries, which constituted the inside trimming of a bonnet, was composed entirely of the berries of the poison swamp sumac, just as they had been gathered, not a particle of varnish, bronze or other material coating them. The bonnet, when worn, would lay this entire mass of villainous berries on the top and sides of the wearer's head, and a few of the sprays about the ears and on the forehead. Stepping into the store, I addressed the proprietor and asked her if she knew that the bonnet was trimmed with the berries of one of the most poisonous shrubs known in the United States. After staring at me in a sort of puzzled way, she informed me that I was mistaken, that she had received those flowers direct from Paris only a week ago.

"Madam," I replied, "there must be a mistake somewhere, for those are the berries of the poison sumac, which does not grow in Europe." She gave me one angry look, asked me to please attend to my own business, and swept away from me to the other end of the store. A few days after this I read in the daily papers

an account of the poisoning of a number of small girls employed in a French artificial flower manufactory in Greene street. I at once guessed the cause. I visited the factory mentioned, introduced myself to the proprietor, told him what I knew about the poison berries—and was rudely requested to make myself scarce. After these two adventures I made up my mind to keep my botanical knowledge (poisonous though it might be) to myself. When in the army I came across a very curious case of poisoning with swamp sumac and poison ivy. A creature having the form of a human being, and wearing the uniform of a soldier, was found in a solitary tent, which was pitched in an abandoned and desolated plantation. This creature's body had the appearance of having been scalded, and his eyesight was nearly gone; in fact, we were afraid to touch him, fearing that he had some terribly infectious disease. But why was he there, alone and deserted? Not even a sanitary guard over him to prevent all communication except by the doctors. He did not seem to care to talk much about himself or his situation, or state why his comrades had left him there to die. Being on the march, all we could do was to leave him extra rations, water and tobacco. But we afterwards learned from members of his regiment that to avoid duty and an engagement, he had poisoned himself by building a fire of green poison ivy and swamp sumac, and had actually submitted himself to a vapor bath of these two poisonous materials. He was a professional bounty-jumper, and had taken this means to get out of the army. He was never heard of afterwards, as he fell into the hands of the enemy. With farmers and farm-hands, in the spring of the year, many severe cases of poisoning have occurred from standing in the smoke when burning brush which was composed of poison ivy and sumac.

—Look not mournfully into the past—it comes not back again; wisely improve the present, it is thine; go forth to meet the shadowy future without fear, and with a manly heart.—*Longfellow.*

Indian Clubs, and the Way to Use Them.—IV.

BY JAMES A. SQUIRES.

EXERCISE 13 (Fig. 15).—Another difficult one. The clubs are swung downwards, parallel to each other, and then raised up behind the back (as shown by the dotted arms), then swung to the front again, and

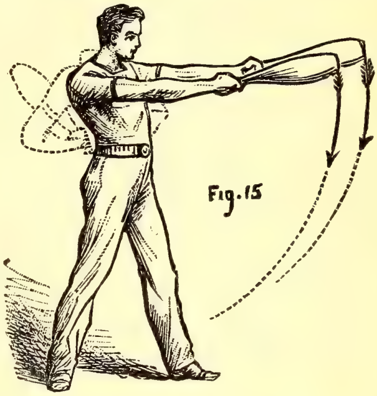

Fig. 15

in a circle completely round at arms' length. The left club executes exactly the same movement as the right in the last exercise (12), but with the right club in this the movement is different. The wrist should be twisted sharply downwards, and the club *tucked under* the right arm; its own weight will then carry it down behind the back, and up to a level and in a line with the right shoulder, reaching that position exactly at the same time as the other club, and both will thus again be parallel, but on the opposite side of the body to that from which they started.

Exercise 14 (Fig. 16).—This is purely wristwork. The arms are extended straight out on each side, and the clubs passed alternately from the wrists in the front and rear of each arm, describing circles on either side. At the same time that one club is swinging round behind the right arm, the other is swinging in front of the left, and *vice versa*. This exercise causes the wrists to become very pliable.

We have now completed our instruc-

tions for the "light clubs." The learner must, of course, acquire the different exercises separately, one by one, but when mastered they can be continued from one to another, making, when so combined, a very effective performance. The movements capable of performance with Indian

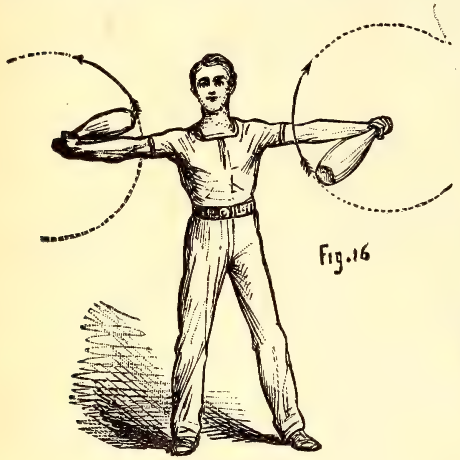

Fig. 16

clubs are almost without limits, but space will not permit us to give further descriptions or illustrations. The performer will find, as he becomes accustomed to the use of these clubs, and attains proficiency in their manipulation, that other movements will suggest themselves, and he will be able perhaps to invent some new and intricate exercise.

Single, or "Heavy," Club Exercise.—Roughly speaking, the weight of a club to be used singly should be about the same as that of the *pair* the performer is accustomed to—*i.e.*, a boy using two clubs weighing 6 lb. each should use *one* weighing just double. This will be found quite sufficient for sustained movements; if a heavier weight is adopted there is danger of over-exertion, and the exercise cannot be performed in a graceful and easy manner. We think the best shape for a heavy club is that shown in Fig. 17, which, our readers will observe, differs from the light clubs in having a "shoulder" instead of a gradual slope from handle to base.

All the exercises described above, with a few exceptions, can be performed with a heavy club, but, of course, with only one hand at a time—the other hanging loosely down by the side (as in Fig. 1). When one arm becomes tired the club should be changed to the other (see Fig. 17), but without the movements of the club being stopped. The exceptions referred to are the wrist twists, which should not be attempted with a heavy club, the strain upon that part of the arm being too severe.

It was with considerable diffidence that the writer undertook the task of penning

Fig. 17

these articles, feeling strongly the difficulty of explaining the numerous and intricate movements in *words;* but, with the aid of the illustrations, he trusts that the directions will prove sufficiently clear to enable those readers of the Young Scientist who desire to become expert in the use of the Indian clubs to succeed fully in their endeavors.

Winter Rambles.—II.

BY A. W. ROBERTS.

INTRODUCING myself to the doctor, I told him of my adventure and manner of capturing the butterflies. He was greatly interested, and in truth patted me on the back for being so enterprising a young naturalist, which of course had the effect of placing me on very good terms with myself. He urged me to keep my win-

dows closed till he could call on me in the afternoon, as some of the butterflies might escape, though it was very rarely that they used their wings during the daytime, they being nocturnal in their habits.

How anxiously I awaited his arrival can be well imagined, and when he did visit me, how much wonderful information I gained from him! In the first place, he informed me that they were not butterflies, but moths, and that their scientific name was *Attacus cecropia*, and by this name they were known throughout the scientific world. He further told me that all known insects, birds, fishes and flowers, etc., etc., had been christened by scientists, so that were I to take one of these moths to a German professor of entomology, who might not be able to speak or understand a word of English, he would call it by its scientific name. This was a new revelation to me; in fact, from the first discovery of these moths in the room up to my interview with the doctor, I began to feel that I was about to enter a mysterious and entrancing wonderland, containing unknown and even unsuspected possibilities of creation.

Fortunately I possessed two redeeming good qualities, which now stood me in good stead. I was a respectful listener and an enthusiastic and tireless questioner. How many boys have slipped up in this world just because they were too proud to show their ignorance about a subject by asking questions, and thus gathering information. He also informed me that I was in possession of enough material with which to make exchanges both in this country and Europe, and thus to get together the nucleus of a very nice collection of American and European butterflies and moths. I could not keep back an expression of doubt at this statement, but when he informed me that 99 per cent. of all the yellow eggs that had been and would continue to be deposited in the room, would, in course of time, become moths, if properly taken care of, and that the hatching out of them was not only very simple and interesting, but also very instructive pastime, it being identical with the raising of the silk-worm cocoons and moth of the silk-worm, that had been practiced so many thousand years. He also gave me instructions how to kill the moths with chloroform, so as not to cause them any pain, and how

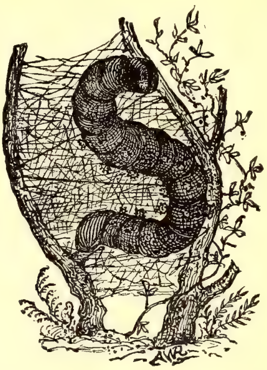

Fig. 1.—CATERPILLAR SPINNING ITS COCOON.

to mount and preserve them for the collectors; also to distinguish the males from the females. After collecting all the eggs together, I spread them out on clean damp cloths (old sheeting), to which the eggs became firmly fastened after the moisture had evaporated, they being coated with an animal glue. These eggs were exposed to the *morning* sun for two hours each day, and at night were brushed over with a goose feather and warm water. In a few days little black mites of caterpillars began to break through the eggs and wander round on the cloth in the most hungry manner. I had brought quantities of elder branches from the woods, which were placed in jars of water, to keep the leaves crisp and fresh. From the tenderest leaves of the elder branches I made a fine hash of elder leaves, which was sprinkled on the cloths. What a sense of deep satisfaction passed through me on first beholding the black mites swarm over the elder hash and begin devouring it with greedy eagerness. Day after day I tended them. Before going to school enough food was given them to last till twelve o'clock (my dinner hour from school), when more food was given them to last till four o'clock in the afternoon. The quantity of food that they devoured in twelve

hours' time was something astonishing. Eating so much and growing so fast, they had to moult or cast their skins every few days. And so I kept on feeding and

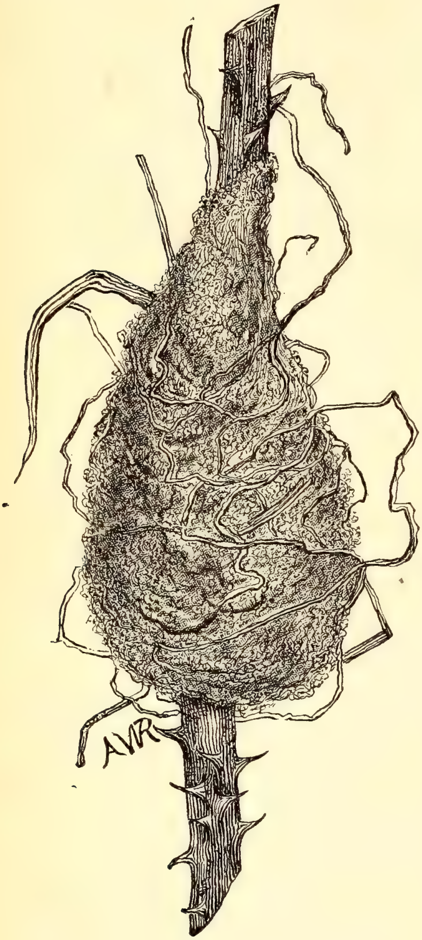

Fig. 2.—COCOON OF ATTACUS CECROPIA.

feeding these voracious creatures, till they had attained one inch in length, when one day I determined to transfer them to the elders growing along the stone walls of Johnson's woods, and let Mother Nature take care of them for the rest of their lives. This was a long and tedious performance, for the doctor had strongly cautioned me never to touch the young caterpillars with my fingers, but always to brush them with a goose feather on to a piece of clean paper or into a clean saucer.

Anxiously I watched them all summer long, as they grew so round and plump and green, with the strange little orange-colored knobs that grew from their backs and sides, and from which sharp and short black spines projected in every direction. At last the fall came, and they began to become uneasy, and ceased to take any more food. Then they began solemnly and slowly to pass down the

Fig. 3.—EGGS OF ATTACUS CECROPIA ATTACHED TO LEAF.

tall slender canes of the elders to within a foot or less of the ground, where they began spinning their cocoons, much after the fashion shown in the accompanying figure 1, and in two weeks' time all the caterpillars had completed this operation and passed into their long winter's sleep, encased as shown in Fig. 2.

How many cocoons of the Attacus cecropia I gathered that fall I cannot remember, but I do know that my room was festooned and draped with them on yards and yards of thread, to which I had attached them, and that in course of time by exchanges I got together not a large but a very satisfactory collection of insects.

As some of my young readers may in their summer rambles come across the eggs of the Cecropia in a state of nature, I herewith give a figure of a leaf with the eggs as usually attached. Such leaves, if kept in the house, will soon hatch out, and the young caterpillars may be fed and reared in the way already described.

Something About Saws.—IV.

BY "OUR NED."

HAVING fairly described, from an amateur's standpoint, the methods of filing and using hand-saws, I will now take up the smaller saws that the amateur will be sometimes called upon to use.

The most common saw in use after the hand-saws and back-saw is the compass-saw, an illustration of which I give at Fig. 1.

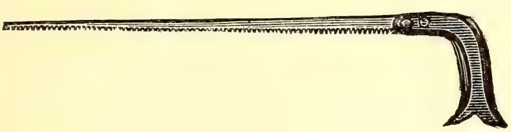

Fig. 1.

The average length of the blade of this kind of a saw is about twelve inches, but many of them are made longer, and some few of them shorter; and the width of the blade is usually about one and a quarter inches near the handle, and one quarter of an inch at the point. They very much resemble the ordinary hand-saw in their general construction, the handle being attached to the blade by rivets, in the same manner as hand-saws, but being of a somewhat different shape. The teeth are formed very much like the teeth of a fine hand-saw designed for cross-cutting soft wood, being, perhaps, thrown a little further forward or made more hooking.

In using these saws much care should be taken when following a line around curves having short radii, or it will be apt to "kink" or buckle, or perhaps break. To prevent this class of saws from snapping, I have often filed them, so that the teeth would pitch towards the handle instead of to the point; this expedient forced the blade to perform its work on the pull stroke, which, in my opinion, is the proper manner for all narrow-bladed saws to labor, unless they are strained from both ends, like the bow-saw shown at Fig. 2, which, being held at both ends, will perform its work nearly as well one way as another.

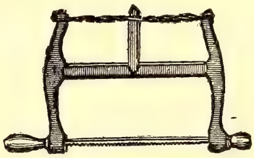

Fig. 2.

Saw blades of this class should be thin on the back, which not only gives them clearance, but aids them materially to follow a line closely round short curves.

The pad, socket, or key-hole saw is something shorter and narrower than the compass saw, and is not fastened to the handle permanently. The blades are sold separately, and may be obtained any length from six to fourteen inches, and containing teeth from eight to eighteen to the inch. Fig. 3 shows the wooden "pad" or handle generally used for these kind of saws; there is a slit or mortice down the whole length of the handle, so that the blades can slip down, leaving only so much out of the handle as may be

Fig. 3.

required. The blade is held in position by two set-screws, which are operated upon by a screw-driver. This is an excellent arrangement, as it enables the person using the saw to adjust its length to suit the work in hand. Saws that have been broken, if not too short, may be used again, but if it is the shank end of the saw that is used, the end should be

filed to a point or rounding, so that it will not catch and stick in the work.

It is more particularly desirable that saws of this kind should have the teeth so shaped that all the cutting will be done on the pull stroke, and it will always pay the amateur to file the teeth so that this will be the case.

Another form of this saw is shown at Fig. 4, where the pad is made of iron in-

Fig. 4.

stead of wood. These are purely American make, and answer very well; they are much cheaper, and for many purposes just as useful for the amateur's purpose as the more expensive pad.

Fig. 5 shows a nest of saws all made to

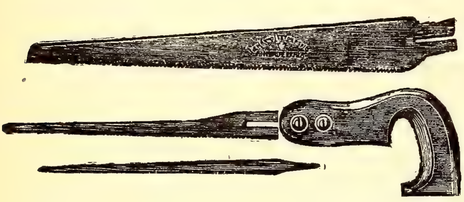

Fig. 5.

fit one handle. This is a very convenient arrangement, and answers very well when an amateur wishes to have a full set of saws. The largest blade is called a table saw, and will answer very well for cutting round large curves. The second-sized blade may be used for a compass-saw, and will cut circles of a much less radius than the table-blade; the smallest blade takes the place of the pad or key-hole saw, but has the disadvantage of being obliged to work with its whole length extending from the handle.

The web-saw, the same as shown in Fig. 2, is a long narrow blade, being of equal width all its length, and having a hole in each end, by which it is connected to the handles which pass through the frame. These handles are made to fit loosely in the frame, and can be turned so that the saw will present its teeth in any direction; and the saw can be disconnected from the handles instantly. The object of having the saw arranged in this manner is to enable the operator to work inside frets or scrolls. This is accomplished by first boring a hole through the stuff to be cut, and then inserting the saw, which must be fastened to the handle again, after which the operation of sawing may be commenced. In using this saw it is necessary to observe that the blade is in a true line and out of twist.

The crossbar of the frame prevents the saw from working in the stuff very far from its edge, thus making it necessary in cases where the stuff is wide to complete the pattern with pad or compass-saw.

Some mechanics are very expert with the bow-saw, and will turn out very fine work with them, but the majority of workmen know but little about them, and the introduction of the jig-saw and the American scroll-saw has completely superseded it in the large workshops and factories, where it was once quite a common tool.

With regard to filing this class of saws, it may be said that all should be treated alike, and the method of filing one applies to all.

As shown in previous papers on this subject, a saw intended for cross-cutting will not rip satisfactorily, neither will a saw cross-cut that is designed for ripping; nor will the ripping or cross-cutting saw do satisfactory work where the fibres of the wood have to be severed at all angles. Hence the necessity of giving the class of saws under discussion, teeth that partake of both the rip and cross-cut teeth.

This is done by making the teeth point pretty well forward, like those shown in Fig. 6, and filed square on the back and

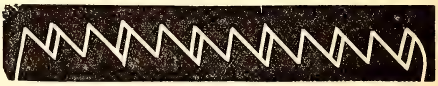

Fig. 6.

slightly beveling on the cutting edge of the tooth. The teeth shown are larger than those used in pad-saws or in saws

intended for frame, but are just about the right size for table and compass-saws. The clamp shown in a previous paper will answer very well for holding any of these saws that are wide enough to be held, and when the blades are very narrow they may be filed in an iron vise or any other similar device.

Casting in Plaster of Paris.—III.

BY MARK MALLETT.

Tools Used in Casting.—Wax Moulding.—Piece Moulding.—Elastic Moulds.—Casting from Natural Objects.

(Continued from page 119.)

THE tools required for casting are few and simple, a basin and spoon being the chief. Yet for backing up both mould and cast, a mason's trowel of small size will be found useful, and a "drag" will be required for smoothing the backs of casts, grounds, etc. A drag some three inches long, such as that shown in Fig. 1, can be cut with a file from any piece of flat steel; an old steel stay-bone, for instance, makes capital drags. For use in mending, and for various purposes, a small steel spatula will be indispensable. This instrument is shown in Fig. 2. It costs about twenty cents. One end forms the spatula, the other is a notched blade for scraping plaster. Those commonly sold have angular teeth, but an improved form has square teeth like those of the drag. These give a far better surface to the plaster. For working on the plaster cast, small gouges of various degrees of curvature (Fig. 3) are sold, also "riffles," which are diminutive rasps; but these things may well be done without by the beginner.

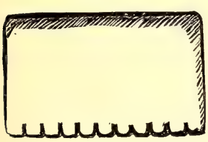

Fig. 1.—DRAG FOR SMOOTHING BACKS OF CASTS, ETC.

Indeed, good and experienced modellers, as a rule, avoid working on the plaster cast as much as possible, choosing rather to finish their work carefully in the clay. A far better surface, whether for delicacy or effect, is to be given in the latter material. It is rather the young modeller, who is in undue haste to cast his work, who will find himself obliged to give much time to touching-up his plaster. The tyro will see defects in the cast which had escaped him in the clay. More especially he will be sure to find that it has a "lumpy" appearance—that there are hills and hollows where there ought to be flat surfaces or regular curves, and this he will have to remedy. Sand-paper, if used firmly, will do this. The right sizes are middle and fine No. 2; coarser will scratch the work, and finer will become choked directly.

Fig. 2.—COMBINED SPATULA AND SCRAPER.

Fig. 3.—GOUGE FOR PLASTER CASTING.

It should be remembered that it is whilst fresh from the mould that the cast is in the best state to be worked upon. There are cases in which the mould may be worked upon with advantage. For instance, suppose the model to be a relief, and that in course of the work the background on which it is formed has lost its original truth and evenness. The projections of the model may render it difficult to get at and correct this. But in the mould, where everything is reversed, the ground becomes the most prominent and easily reached part, and by the use of the drag we can in a few minutes make our ground perfectly true and smooth. Again, we may wish to put a name or other inscription on some part of our model in raised letters. To model raised letters in the clay would be a work of considerable time; by incising them, in reverse, in the mould, which will be quickly done, we shall secure precisely the same result, as the letters will appear raised in the cast.

Some persons object to the brilliant whiteness of plaster, and like it better "toned down." It must be admitted that the effect of toned plaster is more artistic. Yellow ochre imparts a pleasing tone. To give a uniform tint take as much water as there is any possibility of your requiring for mixing the fine plaster

used in facing your cast, and stir in ochre. A slight tinge will suffice—much does not look well, and moreover softens the plaster, and then, as there will be a sediment, pour off your colored water for use into another vessel. It is important to mix enough, as it would be difficult to make a second quantity of exactly the same shade.

The directions given above, so far as they treat generally of the mixing and management of plaster, will equally apply to casting models of other shapes. I have taken a "relief" as an example, because it is the most simple form, and can be cast in a single piece. Such additional instructions as may be required to enable the amateur to waste-mould a model in the "round," can be quickly given.

Instead of a panel, let us suppose that a vase has been modelled. This may serve as an illustration of a simple object in the "round." If we try to mould this at a single operation, we should find it impossible either to extract the clay or to clean the mould. The mould must therefore be made in two pieces.

To prepare this model for moulding, as shown in Fig. 5, we must make a strip of clay, the sixth of an inch thick, and about two inches wide, and stick it edgewise round the vase, so as to divide the latter into two equal portions. This collar can be supported by wire pins, as shown at A, A, A. One side of the vase can now be moulded, for the collar of clay will prevent the plaster from reaching the other side. When the first half of the mould is set, the collar must be removed, and conical holes made at intervals, with the end of the scraper in the edge of the mould thus left bare. These are "key" holes, and as when the other half of the mould is cast, corresponding "keys" will be formed to fit them, they will enable the two halves to be put together with the nicest precision. Some clay-water must be brushed over the edges, to prevent the two halves adhering too closely, and the remaining part of the mould can then be cast. When a model has to be cast in an upright position, as is the case with a bust, or with this vase, plaster cannot be poured upon it; it must be thrown on with the spoon.

The mould being finished, its two halves will easily be forced apart by the mallet and chisel. The clay can then be removed, the mould cleaned, and fitted together again. The keys will ensure the pieces fitting accurately. They then have to be tied together as tightly as is possible. Perfect tightness is to be secured by tying a piece of string or cord, according to the size of the work, loosely round the mould, passing a piece of stick through it, and twisting the stick round and round. When you can screw it no farther, secure the stick from untwisting by tying it fast. You can then pour in the plaster gradually, and well shaking and turning the mould about whilst you do so. When the mould has been chipped off, a little seam will appear on the cast where the two pieces of the mould met, which will have to be cleaned off.

A bust might be moulded in the above manner; but if so, the seam would necessarily pass down the ears and along the neck and shoulders, where it would be highly unsightly. The method shown in Fig. 4 is therefore generally preferred instead. By thus making a "pot-lid," the seam is formed only on the hair, in a part where it will be little noticed, and the opening thus made will allow of every purpose of emptying and cleaning the mould of the head.

Sometimes a portion of the mould may project from the general mass of the work so far, that it would be a difficult matter to mould it *in situ*. If so, it may be cut off with a fine piece of wire, and moulded separately, and afterwards refixed in its place.

As a cast becomes dry, a disagreeable yellow tinge, the result of some impurity in the plaster, will sometimes come to the surface. To obviate this, the cast should be placed with its *back* to a fire, and so dried. As the water evaporates, it will bring out the discoloration on the side by which it escapes, and the front of the cast will thus be uninjured.

Wax Moulding.—The above is the ordinary and most useful method of waste-moulding; but there is another, which is

sometimes applied to delicate models, which will not bear the use of mallet and chisel. This is practiced by pouring melted wax over the model, to form an inner mould, and then backing, as usual, with plaster. This wax mould can be pulled away from the cast, with a little warming, without danger to the finest work.

It is by one or other of these processes that the clay model has always to be transformed into a plaster cast. But if it is required to multiply copies of such casts, or of other suitable objects, other means than waste-moulding will have to be resorted to. This must be done either by an elastic mould or by a piece mould.

Elastic Moulds.—First, as to the elastic mould, which is recommended—by its simplicity, and the ease with which it can be made—for those purposes to which it is suited. Its value may readily be perceived. Fig. 6 may be supposed to represent one quarry of a diaper, which has been modelled, and of which a number will be required. Fig. 7 shows the same in section.

It is plain that no mould formed in a single piece from any rigid material could leave this panel without breakage; but we get over the difficulty if we make our mould of some substance so yielding as to allow it to be drawn over the projecting points seen in the section, and so elastic as, when drawn off, to recover its former shape. From such a mould we can take as many casts, in moderation, as we may require.

Various substances have been used for making such moulds, but that most approved by the best moulders is gelatine. Having first made a single cast by the waste-moulding process, take best sheet gelatine 1 lb., beeswax ½ oz., water ¾ of a pint. Boil them in a glue-pot till they form a thick syrup; rub a little oil (or what is better, hog's lard) over your cast, and then pour on the mixture. It should be used warm, but not boiling. The best and purest gelatine, at about fifty cents per pound, should be used. Some use glue, or cheap gelatine; but these cannot be recommended. When the mould comes to be filled, the plaster grows warm in setting, and the heat thus generated is apt to melt an inferior mould.

Piece Moulding.—By this method objects in the round, objects in relief if they are large, and indeed most objects from which a casting mould is required, are moulded. It is by this method that the cheap plaster images, and almost all the plaster casts sold in the shops, are produced.

[NOTE.—The cuts, 4. 5, 6 and 7, referred to in the text, will appear in next month's article on "Casting in Plaster of Paris."—ED.]

(To be continued.)

Overglaze Painting on Porcelain.

BY AURELIO DE VEGA.

ANTIQUITY *of Pottery Ornamentation.*—The decoration of articles made of clay is one of the evidences of that longing for ornament of some kind or other, which seems to be inherent in man, and we accordingly find that the art of producing on clayware, in such a manner that the result should be permanent, devices of a color different from that of the ware, is prehistoric; the earliest records on this point being in fact induced by the circumstance that excellence had already been achieved in the art.

2. *Superiority of Porcelain to Earthenware.*—For our purpose clay goods may be divided broadly into two classes—opaque and translucent: the former comprising earthenware, majolica, and the like; the latter, porcelain or china. The worth of earthenware may vary between that of the commonest clay crock and the finest piece of stoneware, or majolica; but the value of porcelain, which is of a superior basis, of a more delicate texture, and more expensive to produce, varies within comparatively small limits. That is, of course, at the time of production, and with due regard to the amount of work entailed in forming the object into which it is to be made. The specimens which realize such extraordinary prices among collectors have an enhanced or a spurious value from being ancient or typical, or from the mere determination of a person to become the purchaser. My remarks upon decoration are made primarily with reference to porcelain; not simply because it is the finer and intrinsically more valuable material, but also, and principally, because upon it work more excellent in appearance can be produced. At the same time it will be understood that they apply also to earthenware.

3. *Underglaze and Overglaze Painting Compared.*—Ceramic painting is of two kinds, underglaze and overglaze. The former is executed on the bisque, by which name the ware is known when it has received its first firing, and before it is glazed; the latter is, as its name implies, done upon the glaze, or that glassy surface which gives such lustre to the ware. Each of these modes of decoration has its ardent apologists. Accordingly, it is as well at the outset to admit that of the two kinds, an underglaze painting when executed with the touch which should be employed, and when strictly achieving its true aim, is undoubtedly the finer, comparing as it well may, for effect, with the finest oil-painting. Such a work as this is practically imperishable. On paintings made with, and on, other materials, time lays his finger to their ultimate effacement or decomposition; but an underglaze painting will endure in all its completeness and beauty as long as the ware, on which it is done. An overglaze would, considering the care which would naturally be taken of it, be perhaps but little less enduring; the difference being, that in the former case the colors become united to the body itself, their beauty being developed by the overlying glaze; in the latter they unite with the glaze only. In addition, as regards appearance, the overglaze picture does not, as a rule, present that crispness and boldness which distinguish the perfect underglaze work.

4. *Advantages of Overglaze Painting.*—The foregoing concessions have been made in order that it may not be supposed it is desired to unduly enhance subsequently the value of overglaze work; but, having been made, due recognition can be given to the superior claims of such work to the attention of the average amateur. These are numerous and important.

(a.) The scope of underglaze work is limited by the smaller number of colors available. In order that the bisque painted in oil may be brought into a condition to take the glaze, it is necessary that it should be raised to a red heat, so that the whole of the oil, which would of course refuse to combine with the glaze, which has a watery medium, may be dissipated. There are, however, only a few of the pigments obtained from the same sources which supply those for overglaze work, that can, after passing through such an ordeal, resist the action of the constituents of the glaze; some changing in tone or tint, others disappearing altogether. Hence overglaze work has the great advantage of a much wider selection of colors, and consequently a more extended range of subject.

(b.) Not only are underglaze tints less numerous than overglaze, but with a few exceptions, they do not comprise those brilliant, not to say gorgeous hues, which can be produced in the latter, and which are so essential in certain styles of decoration. An underglaze painting is, generally speaking, quieter than one done over the glaze; and hence, frequently, with a view to perfect the effect sought to be attained by work on the bisque, the assistance of enamel color on the glaze is called in.

(c.) Overglaze work does not make such demands upon the judgment of the painter as does underglaze. In the case of the latter the hue of the pigment as laid on is very often entirely different from that developed in the glazing; whereas, in the former case, the color laid is, as a rule, the same as that which will appear fixed after the firing. There is frequently also, in underglaze work, a difficulty to determine the exact depth of color employed, which, when at all existent in overglaze, is so to only a very slight extent. And, generally, overglaze work is less troublesome than underglaze.

(d.) The expense of glazing is considerably greater than that of simple firing, which is all that is necessary to fix the painting in overglaze work.

Hence it is abundantly evident that for the amateur whose desire is presumably to produce, with a view to decoration, an effect brilliant as well as artistic, painting in overglaze or enamel colors offers at once the wider and cheaper, and practically, equally enduring means of gratifying his wishes.

5. *Prospectus.*—The remarks which follow will be found to afford, so far as is possible in writing, a complete course of instruction in all that essentially appertains to overglaze painting. It will be readily understood that written directions, considered alone, sometimes fail—taking for example the subject of matching tints—to bring about the *exact* result desired or described. The earnest student, however, fairly appreciative, and possessed of ordinary powers of perception, will meet with a full and sufficient guide to enable him to embody his ideas in color.

I propose to consider in order the nature of porcelain and its glazes, and the mode in which the latter affect the appearance of the painting; the scope of the amateur's work; the apparatus and appliances necessary or profitable to employ; and the vehicles which should be used in laying the pigments. A work will then be undertaken in monochrome, or one color shaded either with itself or with some allied color; in carrying this out the several processes best adapted for outlining and laying the background under different circumstances will be reviewed. A detailed description will then

be given of the standard colors, or those in regular use, and ordinarily procurable; of their mutual behavior in mixtures, and of the manner in which composite tints generally may best be obtained, and with this information in hand work in colors will be commenced.

6. *Porcelain and its Glazes.*—In order that greater discrimination may be exercised in subsequent operations, it is desirable that the nature of porcelain and its glazes should be understood. I do not propose to give a history of pottery, or a detailed description of the processes employed in the production of that beautiful ware now so easily and cheaply obtainable. Such a course would serve no useful purpose. A section on the subject would be highly interesting, but the greater portion of the information it would afford would be of no practical avail, and complete descriptions are readily attainable in public libraries, and are more fittingly found in the pages of an encyclopædia, or a Dictionary of Art or Manufactures, than in a paper of such a series as this, the main object of which is the satisfaction of the wants of the practical amateur *painter.* It is, however, essential that the painter who is desirous of attaining something more than mere mediocrity in his art, should be possessed of correct information respecting the two particulars to which I have just referred, as without this knowledge it is very probable that he will fail—however well he may have worked—to realize his ideal, seeing that similar work executed with equal care upon two glazes of different descriptions may produce results so entirely different, that in one case the liveliest satisfaction may be experienced, in the other the keenest disappointment.

Porcelain, then, is of three kinds, technically known as *Hard*, *English*, and *Soft*, the last being also called *tender*, or *spurious*, and the first also *genuine.*

(a.) Hard Porcelain.—The body of hard porcelain is essentially composed of two substances, both of which occur naturally: 1. Kaolin, or as it is sometimes called, China clay, an argillaceous earth, the most valuable beds of which have been found in China and Japan, in Saxony, in France near Limoges and near Bayonne, and in England in Devon and Cornwall—the English variety resembling the Chinese and Japanese rather than the Continental. 2. China stone, a quartzose felspar, here called "crockery stone." These two substances occur in the formation called "graphic granite," but whether they have resulted from the decomposition of the granite, a further stage having been reached in the case of the former than in that of the latter, or whether they are constituents of imperfectly formed granite, the latter being more developed than the former, is not yet determined. Their origin is, however, noticeable, as they are causative of the hardness of the ware. By whatever means brought about, the important point is that the stone contains a large portion of alkaline matter, but little of which exists in the clay, and is accordingly fusible, or capable of being reduced to a molten mass, while the clay is infusible, or under heat retains its earthy character, and becomes of a brilliant opaque whiteness. The stone thus acts as a flux to the clay, and it is to this flux that nearly all hard porcelain owes its translucency.

The principal seats of this manufacture are the district round Limoges and Sevres. Hardware is also made in districts bordering on the Rhine (Sarreguemines, Saarlouis, Vaudrevange, Mettlach, Maastricht), at Meissen (Dresden), Berlin, Vienna, St. Petersburg, etc. The Chinese and Japanese ware also belongs to this class. In England hard porcelain was first made by Cookworthy at Plymouth (A.D. 1760), subsequently at Bristol, and later at some of the Staffordshire works.

(To be continued.)

Amateur Boat-Building.—I.

IN order to prevent any misconception as to the scope or object of the "Hints on Boat-Building," which we purpose to offer in the pages of the YOUNG SCIENTIST, a few words of introduction may be expedient.

In the first place, then, the "Hints" are not intended for the instruction of professional boat-builders. They are, on the contrary, mainly addressed to the large and increasing class of amateurs who desire to build their own "boat" at small expense. The instructions conveyed will, therefore, necessarily be of an elementary character, and the general style of the papers somewhat discursive.

Secondly, it must be distinctly understood that in describing any particular manner of performing an operation, or recommending any special style, we shall not mean that such are the only ones—nor, indeed, necessarily the best. They will be simply those which commend themselves to us, and may, perhaps, in many cases be taken as hints for the ingenuity of our readers to improve upon.

In starting, let us briefly describe the more usual forms of boats used on rivers.

The simplest form of boat may be taken to be the flat-bottomed, square-ended concern known as a "punt," and much in use for angling purposes. This form of boat is very safe, and is capable of going up shallow and weedy or muddy streams, where it would be impossible to get any-

thing else along. A pole is frequently used as the means of propulsion in such cases. Punts are sometimes made in much improved forms, combining lightness and very small draught of water. The punt is one of the easiest boats for the amateur to begin upon.

Boats constructed to accommodate one person are usually termed "sculling boats," from the word "scull," applied to oars of the kind and dimensions adapted to the manipulation of one individual, who holds a scull in each hand.

The name "dingey" (pronounced with the g *hard*, as in "go,") is variously applied. A short, strong, tubby boat is usually understood by the term; but it is also sometimes given to a short skiff of sixteen or seventeen feet in length.

The pair-oared "gig" and "skiff" are two very common and useful forms of rowing-boat. Some skiffs closely resemble the gig; there are, however, always minor points of difference. For example, a skiff is curved between the rowlocks, which is not the case with a gig; that part of the keel which ends at the prow is also much more perpendicular in the gig than in the skiff.

A boat which is constructed to combine in a measure the qualities of a pair-oared boat and of one propelled by sculls is known as a "randan." Here the sculler sits amidships, with one rower before and one behind him. This arrangement may be considered somewhat unsightly; but it has some not inconsiderable advantages for travelling over long distances.

Sometimes a pair-oared boat is fitted with rowlocks for double-sculling, which has of late come rather into fashion. Where there is a marked difference in reach between two oarsmen, double-sculling has a distinct and undeniable advantage over rowing. Occasionally, also, a randan is fitted up for three pairs of sculls, if required.

Amongst other varieties of boat we may specify the "funny," which is an open outrigged sculling-boat, alike in form at both stem and stern, and having a keel which falls away at each end in a sloping curve. The "whiff" is a similar boat, but has an upright stern, not sloped away as the bows are.

"Outrigged" boats are those in which the rowlocks project laterally outwards, in place of being formed on the side and in the substance of the boat itself. The rowlocks, or "rullocks," are generally borne on light ironwork, and as their projection enables them to afford sufficient leverage to the oars, the boat can be correspondingly diminished in width, and greater lightness by this means obtained. Boats of this kind are made of various sizes, from those adapted to contain a sculler only, to those suited for two, four or often eight oars. There is considerable variety in shape also, within certain limits. When the boat is sharp at both stem and stern, as just described in the sculling-boat, it is termed a "wherry," but when made upright at the stern, like a whiff, it is known as a "cutter." Wherries are seldom built now for more than a couple of rowers, as when there are more, provision is usually made for a "coxswain," or steerer, which necessitates an upright stern-post.

Racing-boats range from twelve feet in length upwards; they are built as narrow and with as light a draught as it is possible to obtain, and in order to combine as much strength as can be got, consonant with the lightness, which is indispensable, the very best materials must be used in building them, as the finest pine-wood and mahogany.

These boats are never provided with a keel, nor are they ever what is sometimes called "streak-built," or "clinker-built," both which terms are used to signify that the boards on the side of the boat overlap each other as they ascend, something like the "clap-boarding," or "weather-boarding," of a wooden barn. In the racing-boat the boards are, on the contrary, quite flush or level on the exterior of the vessel, and with a surface as smooth both inside and out as sand-paper and polishing can secure.

The canoe, which has become so popular of late years, is, in the main, a reproduction, or, rather, an imitation of the boat in use amongst various savage and semi-civilized tribes. Of these the fragile canoe of birch-bark, fabricated by our Indians, and afterwards adopted by the French settlers in Canada, represent one modification. In these slight structures the Indian will shoot in safety the many rapids of American rivers. The skin canoes of the Esquimaux are in many respects analogous. Not far dissimilar from these last must have been the light canoes in which our hardy British ancestors pursued their fishing in the deep streams and broad estuaries of ancient Albion. The lineal descendants of those light barks are found to this day in use on the Severn and the Wye, where they are known as "coracles." Gibson, the translator and editor of Camden, thus describes this canoe of the Severn: "The fishermen in these parts use a small thing called a coracle, in which one man being seated will row himself with incredible swiftness with one hand, whilst with the other he manages his net, angle, or other fishing tackle. It is of form almost oval, made of split sally"—(sallow, or willow)—"twigs interwoven, round at the bottom, and on that part which is next the water it is covered with a horse-hide. It is about five feet in length and three in

breadth, and is so light that, coming off the water, they take them up on their backs and carry them home."

The Indians are able in a similar manner to carry their bark canoes round any particularly dangerous or impracticable rapid, at what is called in the *patois* of the Canadian-French a *portage*.

Canoes of the present day are very various in their patterns, as most makers and owners have some special manner of their own in constructing them. The shooting canoe with a flat bottom, in the style of the punt, is the most easy to build. Next to this, perhaps, comes the kind known as the "Rob Roy," from Mr. Macgregor's celebrated little bark. Those provided with sails and shifting keels offer considerably more difficulty in construction. In fact, a good, light, strong, adaptable canoe may fairly be considered a thing which presents many difficulties to the amateur boat-builder.

Amateur boat-building may be said to be one of the most recent forms of unprofessional occupation. Why it should have been so it is hard to say, as much of it does not make a greater claim on the amateur's skill than many other things which he takes up to freely. All that is required is some knowledge of the use of carpenters' or joiners' tools. Of course, few would aspire or hope to make a first-class racing-boat, which is the acme of delicate workmanship, and tasks the best abilities of the professional builder.

There can be little doubt that to the riverside, or sea-shore dweller, who can turn out a decent skiff or other boat in a fairly respectable manner, not only is the pleasure and satisfaction of the successful work great, but the actual money-saving is very considerable.

Some years ago, perhaps, four dollars per foot length might be taken as a rough average of price among boat-builders. Since then materials have risen in price, and the number of good hands in the trade has, perhaps, not increased in a ratio sufficient to keep up with the popular demand for pleasure boats. The result is that prices rule now probably not much less than five dollars per foot on an average. Of course, however, it must be borne in mind that the amateur cannot expect to rival such craft as we have in view, but he can assuredly provide himself with a very good substitute at a very big deduction.

One thing that it is well should be borne in mind is that the amateur may not improbably find himself possessed of some natural "knack" which will stand him in better stead in boat-building than in nine pursuits out of ten, for a reason which will appear as we progress, and in this connection we give a suggestive extract.

"A well-built boat," says a recent writer on the subject, "when in the water seems of itself to suggest life with spontaneous movement; the reason, no doubt, being that the beautiful curved lines which enclose its shape have been more or less adapted from forms that nature has bestowed on living animals. A boat, too, seems to have the separate individuality of a living thing, as all those who have had much to do with ships or boats of any kind will readily allow. Two boats constructed as far as possible on the same model will be found to vary in their 'going' more than would be believed possible by the inexperienced; one, probably, being much more difficult to turn than the other when it has once taken a direction, and in a variety of ways showing what seems almost wilfulness. This seeming inconsistency is probably owing to the extreme subtlety of the ever-changing curves in the form, which, however carefully they may be planned and measured, must at last depend actually upon the eye of the builder, and are consequently subject to variations in common with all true human work."

Like most operations, except the very simplest, boat-building divides itself naturally into two main divisions, viz., those of designing the thing required, and of working out the design. For the purposes of the amateur no great knowledge of drawing is needed. Still it would be a fatal mistake to begin to build a boat without some design on paper to work to—at least, for the amateur. He cannot be expected to possess the "rule-of-thumb" knowledge of the professional workman, and, therefore, the more carefully he designs his ideal craft, and the more minutely he develops the details on paper before beginning the actual building, the more certain he is to attain a satisfactory realization of his hopes.

To aid him in this we will in our next paper enumerate a few simple instruments necessary, and give some details as to the method of producing the preliminary drawings, viz., the "sheer plan" or representation of the boat in profile projection, the cross-sections, and the water-lines.

(To be Continued.)

Decalcomanie.

DECALCOMANIE can be applied to the ornamentation of all kinds of manufactured articles, such as sewing machines, japanned ware, safes, agricultural implements, carriages, sleighs, furniture, pottery, etc. The method of applying is so very simple that it requires little time and skill to become proficient in it. As an art

amusement for ladies nothing has ever been introduced by which such gratifying and pleasing results can be accomplished with so comparatively little trouble and expense.

An entirely new manner of ornamenting (equal to hand-painting) silk, linen, cotton, and other fabrics, suitable for decorating odor bottles, tidies, pin-cushions, lamp shades, sachets, and, in fact, any article made of silk, linen, or cotton, is as follows: Heat a small smoothing iron or a roller used for the purpose, to the usual heat needed for ironing. Then take the transfer and dampen the back of it with a moderately wet sponge. Place the face of the picture on the article at once, lay a thin sheet of paper over it, and press with the iron or roll with the hot roller. Then pull off the paper and the transfer is completed. To make the picture substantial it is necessary to remove the gloss that remains on it when transferred. This is done by again applying the damp paper just drawn off, or, still better, some other damp, water-absorbing paper, and pressing it with the hot iron. The same should be done if the picture does not stick well to the fabric, because the iron was not hot enough or not sufficiently pressed. On the other hand, if the iron is too hot or too much pressure used the paper may stick to the picture. In this case wet it again and it will come off.

Following are the directions for using transfer ornaments: Observe first that pictures showing the colors can only be used on white or very light-colored ground; those that have a covering of white or metal leaf can be used on any color, light or dark. To transfer on glass, porcelain, wood, or any article that is painted or varnished, proceed as follows: Give the picture, that is the side showing the metal or colors, a thin coat of quick-drying varnish, being careful not to go beyond the outlines. Let it remain five or ten minutes until the varnish is right tacky; then place the picture in the proper position on the article it is to be applied to, dampen with a wet sponge, pressing it at the same time, until the paper is thoroughly saturated and adheres smooth. Pull off the paper carefully, and when removed press the picture well with a damp sponge, until every part adheres well; wash it clean to remove the gum, and dry it. To brighten the brilliancy of the colors a light coat of the same varnish may be applied. When the preparations known as cement and detergent are used, it is not necessary to trace the design, as the detergent will remove all the stains. A rubber roller, such as is sold by dealers, is very convenient to press on the picture well, and prevent blisters and uneven places. To apply the pictures to uneven surfaces it is necessary to dampen the paper before laying it on the work. This can be done best by taking two sheets of blotting or other unsized paper, dampen them thoroughly, but don't let any water remain on the surface. When the picture is coated and dry enough lay it between the dampened paper for ten or fifteen minutes. It will then be found soft and pliable, and will easily take the shape of the article. To transfer on paper, a solution of gum arabic, about the consistency of mucilage, is the most practicable. Give the picture a coat of it, and lay it on the surface to be applied to, pressing it well or rolling with the roller. Let it dry for about ten minutes, and then take it off as usual. Remove the gum with a damp sponge, and dry it with a clean piece of linen.

Our Girl's Department.

This department is intended exclusively for "Our Girls," and we hope to make it both interesting and instructive, and to this end we ask our young lady readers to assist by contributions, suggestions, or illustrations. There are thousands of little things that can be, and have been, made and done by young ladies, pertaining to decorative art, needlework, etc., etc., that would be gladly followed but for a want of knowledge on the subject, and we know of no more pleasing task for a lady than that of teaching her younger sisters that which they are anxious to learn, and which may prove of real benefit to them in the future, as well as being useful and interesting for the present. We trust we will have no difficulty in persuading those who have something nice to show or speak of, to make use of this department. Remember, it is open to all, and if you have anything worth knowing suitable for this column, send it along, and we will give it our best attention. Do not be afraid to write because you may fancy your composition is not perfect, or have other scruples of a similar kind. Do the best you can, and leave the rest to the editor of this department, and we are sure you will be pleased with your work.

THERE is but one happiness—duty. There is but one consolation—work. There is but one enjoyment—the beautiful.—*Queen of Roumania.*

— Generosity is the accompaniment of high birth: pity and gratitude are its attendants.—*Corneille.*

— Although men are accused for not knowing their own weakness, yet perhaps as few know their own strength. It is in men as in soils, where sometimes there is a vein of gold which the owner knows not of.—*Swift.*

— She who has no resources of mind is more to be pitied than she who is in want of necessaries for the body; and to be obliged to beg our daily happiness from

others bespeaks a more lamentable poverty than that of her who begs her daily bread.—*Colton.*

—"Almost all the advantages which man possesses above the inferior animals arise from his power of acting in combination with his fellows, and of accomplishing by the united efforts of numbers what could not be accomplished by the detached efforts of individuals."—*J. Stuart Mill.*

—An artistic lamp is in hammered copper, and having the base adorned with a white rose and leaves in silver, with varied oxidations.

—A fancy is shown for using ivory for handles, etc., with the brown outer tint of the tusk retained. It harmonizes well, with representations of the antique in metals.

—Miss Phipps, a pupil of Professor Pitman, at Cincinnati, has taken charge of the instruction in wood-carving at the American Art School in Twenty-third street.

—Stained glass is used effectively in doors at the end of hallways and in those leading into the garden. For drawing-room doors leading into hallways, the upper part is a stationary glass sash, from beneath which hang the curtains.

—Fashionable work-baskets are of twisted straw work, somewhat clumsy in make, and decorated with single silk balls as large as hazel-nuts depending from twisted silk cords. They are usually lined in some bright-colored material, and finished off around the edge with ruching of satin.

—Embroidery upon leather is gaining greatly in favor. The finest kid is usually chosen for this work, and the patterns are the same as for embroidery in satin stitch. The design is traced upon the material, and then small holes are made by a stiletto along the lines, to enable the needle to pass through readily.

—A fashionable foot-stool is a shaggy dog lying in front of a lady's chair, with head alert and fore-paws stretched out. He neither barks nor bites, although of most natural appearance and wearing about his neck a chain; neither does he run away, and although costing $18, is not accounted an expensive beast, considering the insignificant cost of his keeping.

—A very beautiful screen is in three panels of illuminated leather, upon which designs have been painted in oils. The outer panel has a spray of flowering magnolia, the centre one a vase over which conventionalized roses drop in wild profusion, and the last, a bough laden with russet apples. The leather itself is embossed and mounted in a carved mahogany frame.

—The fancy squares sold at the Japanese stores are much used in making lambrequins. They are cut into diamond-shaped pieces, and one point in each is attached to a corresponding point in another, while in the interstices small stars of colored cloth are inserted and caught to the two upper and lower points. To each point a tassel is attached, and the effect is very good indeed.

—If a person wishes to transfer a pattern instead of having it stamped, take a piece of tracing paper and place it over the cloth to be marked, between the cloth and pattern; trace your pattern all over carefully, and you will find the cloth marked. If a person is where they cannot procure the paper they can make it as follows: Take a sheet of writing-paper, not too thin, and rub it all over with warm lard; then pour on lampblack in fine powder, rubbing very smoothly; repeat several times; when all loose powder is removed lay it aside for two days to dry.—S. X.

—A very pretty walking dress is made of dark green repped goods of soft wool. The skirts are attached to a jersey bodice, the front of which is braided in military style in a raised design, which is broad just below the throat, and then narrow-

ing gradually until it reaches a point just below the waist. Here it meets with a wide design in the braiding, which extends from hip to hip. The effect is very becoming to slender figures. The bodice buttons down the back; the close sleeves are braided nearly to the elbow; the skirt is edged with a wide ruche, above which are broad, upright box-plaits, long enough to reach to the scarf of twill, which is draped just beneath the braiding above described.

A lovely tea-gown, representing the genius of Hentenaar, was displayed by a Broadway house a short time ago. Never did a princess out of a fairy story own a more exquisite and dainty robe. It is made of mauve-tinted surah embroidered in silk, with white and blush roses entwined in leaves of palest gold. The back is cut a la Watteau, with a trailing vine of the embroidery reaching from the top of the pleat in the back to the foot of the trained skirt. Around the bottom is a wide ruche formed of four separate strips of pale silk—mauve, white, pale pink and pale gold—fringed on each side to the depth of two inches, and then plaited up together, the whole forming a feathery mass of coloring, matching perfectly every tint seen in the tea-gown itself.

— To apply water colors to steel engravings proceed as follows: First prepare the engravings with a coating of "Newman's preparation for sizing," which may be obtained at any large art dealer's store, at a cost of about sixty cents a bottle. This will harden the surface, so that it will not absorb the color. By all means, however, water colors should be used instead of oil, both for engravings and photographs, though the latter can be colored with oil paints if it is very finely done. In using water colors, use those mixed with Chinese white, which makes them opaque. These can be bought already prepared, under the name of gouache colors, and are much better for painting photographs than the transparent colors. The Egyptian water colors are used a great deal also for such purposes, and are floated on in tints instead of touched in with a brush. A finer finish, however, can be obtained with the gouache colors.

— To make a nice cushion take two pieces of Turkish toweling, cretonne, or patchwork of crazy design a yard long and a half yard wide. Make a cushion of ticking half a yard square; sew the sides of the covering together, except one of the narrow ones; put in the cushion and tie a wide bow of silk or cretonne at the point where the cushion ends. The end left open should be faced or finished with fringe. The whole when completed resembles a bag of meal. This form of a cushion is among the latest novelties. At the exposition held in this city very beautiful ones of this style were exhibited and very much admired. Handsome ones for the parlor are made of silk or satin, with a large monogram worked in the centre. If the slip is of blue satin, the tie is of pink; if of cardinal, it is fastened with olive or old gold.

— The *Art Interchange* says, in giving directions for painting on plush: "If you have a drawing-board of proper size, fasten your plush to it smoothly and evenly by means of thumb tacks, being careful that the silken nap runs downward. Use only a good quality of plush, as it takes the color better, and with a skilful worker needs no other preparation than stroking it smooth with a soft brush. Squeeze the color from your tubes on a piece of blotting-paper, which takes up superfluous oil. It is premised that the outline of your design is already on the plush, so lay on the coat generously to form a firm body for the design. Allow this coat to dry completely, or the after painting may crack. A plush painting will need more than one sitting, as each coat must be thoroughly dry before another is applied. The design should be bold; no two parts should overlap or touch each other. This is the best method, it is claimed, for the best qualities of plush. For inferior plushes without much nap-body, outline your design on the plush, and coat the plush within outlines

of design with gum-arabic solution; let it dry thoroughly, and then proceed to paint as described above."

Floriculture for Girls.—II.

WHILE you wait for May weather—weather befitting the May of the poets, when the ground shall get moist and mellow, the grass green, and the winds warm, and gardening shall seem an inviting pastime—what can you do in preparation for its coming? I think you will find it a pleasant experiment to try starting some seeds (say browallia, pansy, verbena, mignonette, and aster seeds) in the house, in the hope of obtaining early blossoms.

Take, then, a shallow box, and put in it an inch or so of drainage (broken flower-pots make the best); then fill with good soil crumbled finely as possible; get a piece of lath or other flat stick, and with the edge of it mark little trenches for your seed, scatter in rather thinly, and draw the earth over, pressing with the flat side of the lath afterwards to firm the surface; be sure and label each row, so that you can identify them when they come up; water lightly, and set in a sunny window in a temperature not lower than sixty degrees.

When the seedlings have formed their second leaves, thin out, and plant those you remove in a box like the first. This thinning out requires great care. The roots of the plants not moved must be disturbed as little as possible, and those taken out must not be left with roots exposed longer than can be helped, and must be handled very gently when replanted. When you press the soil round them take care not to pinch the little stems, or you may unwittingly destroy half your young family, and wonder, when you presently see them withering, what has happened to them. After transplanting, shade from the sun for a day or two until they seem to be growing again.

By the middle of May it will be safe to plant seeds in the garden, and if you have saved half your seeds for out-of-door sowing, it will interest you to see how, under the influence of the warm spring sun, they seem trying to catch up with their earlier-planted associates.

Now equip yourselves for work "in the garden," and to that end procure a hoe, a rake, a trowel, some pointed sticks, and a watering-pot. If all of you had big rubber aprons which reached below your knees, and on which you could kneel when necessary, it would be a useful addition to your outfit.

The field is before you. It may be a back yard in the city, or a lovely garden in the suburbs, or a margin of the vegetable garden allowed you, in the country. Whatever it is, I hope the soil has been well dug, and hoed, and laid open to the sun, and that *you have assisted* at the operation. Now you may have house-plants to bed out, and seedlings to set out, and seeds to sow, and the questions arise, Which? and Where? In this the taste of the plants must be consulted as far as your circumstances will allow, for one calls for sun, and another for shade, and a third for moisture, and will not be denied without sulking. Using, then, your best discretion in placing them, you proceed first to set out your house-plants. They have been watered well over night, and all straggling branches and weakly shoots have been cut off (by a slanting cut with a sharp knife). Holding a pot upside down, with the stem of the plant between your fingers, tap it sharply and lightly against a wall, or with the handle of your trowel, so that the soil is loosened from the sides, and draw off the pot with your other hand. Do not crumble off the earth from the roots, unless it is mouldy. Set the plant in a hole dug for it, and settle the earth firmly round it with your hands; then rake the bed thoroughly and water, and leave to summer's care until the usurping weeds appear and you are summoned "to the rescue." Always keep your beds well weeded; you will take twice the pleasure in them that you could possibly get from half-raked, slovenly-looking borders.

With your seedlings be careful. Lift them from their box, with plenty of soil

round their roots, into little horns of paper, and carefully slip from these into the place prepared for them; plant some distance apart, to allow for growth; gently press the earth down round them, and lightly rake over the border, water, and shade for a day or two with papers or matting, until the plants have taken root, which you can generally tell by their beginning to put out new leaves.

In planting *seeds* you must have a mental view of the plants they will make; here you see how your taste and imagination is appealed to. You must avoid planting low-growing varieties where they will be hidden by tall ones, and be sure of having agreeing colors next each other. Put labels by each kind of seed you sow; here the pointed sticks come in. Now keep a watchful eye for stray cats and chickens, and dogs with bones to bury; none of these creatures feel any compunction at uprooting your choicest seedlings, and undermining your favorite plants, and scattering your carefully-planted seeds.

After your garden is once planted, your work will be to keep the weeds at bay, and water when the dews and rains forget to visit you. As the plants grow, a little amputation will not hurt them; if you take off here and there a straggling stalk, and pinch off buds that appear in the wrong places, you will have a family of well-shaped plants, not a deformed or crippled one amongst them.

Let me give you a list of flowers of an accommodating disposition, that will grow with the very smallest encouragement. The following comprise a good range of colors: Phlox drummondi, portulacca, dianthus heddewiggi (Indian pink), pansy, browallia, mignonette, and sweet alyssum; and for climbers, sweet pea, maurandia, and nasturtium. These are a very few from the very many that may be grown in an ordinary garden-lot, but enough to experiment on, and enough to afford you much delight, if, as they are likely to do, they flourish under your care.

Bulbs planted last autumn should be blooming now, and I hope you will remember them next fall, so that you may have them to brighten the garden while the seeds are just starting, and to help you wait with patience for the summer flowers. Hyacinths, tulips, and narcissi should make your borders gay, and crocuses and snowdrops come up through the grass-plot, or cluster under trees, or in any place where a bit of spring brightness would be most appreciated.

I cannot, in one little talk, tell you more than the very initiatory steps to the growing of flowers, and all I could say would still leave you the greater part to discover by experience; but if you will bring what Nature has given you of enthusiasm, patience, and common sense to bear on your experiments, I am not afraid that you will fail of good results. Good speed to you in your gardening!

NELLIE HOOPER.

The Stephanoceros.

BY MARY H. WHEELER.

The microscope is on the stand,
  The lighted lamp in place;
With slender forceps in my hand
  I draw from out its case
A tiny water-milfoil spray,
  Of lovely, verdant tint,
And focusing the usual way,
  Look down the tube asquint.

"What do I see?" A cell-built leaf,
  With thorny apex crowned;
But what is that long hairy sheaf
  Attached to something round?
Round, did I say? 'Tis oval now,
  And shining like a gem;
And fastened to the leaf somehow
  By something like a stem.

The stem grows longer. See, O see!
  What is the thing about?
The hairs spread fanlike; can it be
  'Tis turning inside out?
There now it lies, a form complete,
  With five long arms spread wide;
And mark that organ's steady beat
  In its transparent side.

The arms have formed a cup, you see,
  The long hairs meet and cross.
Ah, now I know it must, must be
  A Stephanoceros.
O King of Animalculæ!—
  For surely thou art crowned—
Long vainly have I sought for thee,
  But now you're found! you're found!

A Danger and Its Remedy.

A RECENT issue of the *London Lancet* contains a long warning in regard to the toy known as the "puff and dart." The toy is a very old one, and consists of a long tube, through which a dart or pellet is forcibly propelled by the breath. The *Lancet* claims that practice does not diminish the danger which attends its use, for which assertion the following reasons are given:

"A deep breath must be drawn before blowing into the tube, and it is extremely likely that this will not be concluded when the tube reaches the mouth in the act of applying it quickly. Again, any person may be seized with a fit of coughing on the first effort to expire, and the dart is, under these circumstances, extremely likely to be drawn into the mouth, and to pass into the larynx. If it does so enter, it is probable that it will go far in, as the worsted padding will form a soft plug; and the needle-point being outwards, the next expiratory effort is almost sure to drive it into the wall of the larynx or bronchial tube, rendering extraction exceedingly difficult, if not altogether impracticable. In two of the cases which Dr. Bruce has described death ensued after much suffering. It is a peculiarly melancholy and distressing death to die, this slow killing by a foreign body in the lung, and the distress of patient and friends is necessarily greatly enhanced by the reflection that the pain and loss of life have been the results of recklessness. Surely, such toys as this apparatus of 'puff and dart' ought not to be sold to children, and should be abandoned by adults. The ordinary pea-shooter is a foolish instrument of the same class, though not, of course, so deadly in case of accident, as the pea is small and round, and may be coughed up; but there are cases on record in which even so small a body as a pea has caused death by being gradually drawn into a small bronchial tube, where it has acted as a 'pea valve,' passing a little further in with each deep or prolonged inspiration, until the air has been wholly pumped out of the lung behind it; and disease has been set up in consequence, partly by its pneumatic effects on the organ, and partly by the irritation and inflammation its presence has set up. Life is sufficiently beset with perils which are unavoidable. It is needless to make new dangers, and it is particularly silly to do so when there is really very little, if any, amusement to be got out of the diversion to which the peril is attached. We trust the perils of 'puff and dart' may be made extensively known by our readers, and that the foolish game, with its dangerous apparatus, may quickly fall into disrepute, as it is not worth the risk run."

That the *Lancet* does not exaggerate the danger of "puff and dart" we fully believe, but as it will be almost impossible to abolish the use of this toy, we would suggest that all manufacturers and dealers should be compelled to place cross wires in the end of the tube next the mouth. In this way a free passage may be secured for the propelling air, while there can be no danger of the dart passing backwards into the lungs.

Those of our readers who may have occasion to write to advertisers for circulars, samples, or other information, will do us a great favor, and advance the interests of the YOUNG SCIENTIST, by mentioning our paper.

The good work goes on apace. Every day adds new names to our list, and thus the circle grows larger. We are never tired of receiving new names, new autographs, new friends. All are welcome to our ranks, and we trust that each one whose name we have now entered on our

books will induce some friend, brother, sister, or near relative to join our ranks. Every new-comer adds to our power to make the paper better, and, if possible, more complete. By January 1st, 1884, we want 25,000 new subscribers, and when this occurs the paper will be made larger, without change of price.

Cheerfulness is an absolute necessity to healthy young people, and to all people, for that matter, who desire to be healthy. True, cheerfulness, in a great measure, depends somewhat on the temperament of the person, as well as grace and a good healthy conscience. Boys and girls should always be cheerful, always good-natured. The little troubles, disappointments, and adversities that beset the ordinary course of a boy's or girl's life, are but evanescent, and to-morrow's sun will disperse them as it does the morning's mist. To be cheerful is to be happy, and happiness should be the constant companion of youthfulness.

Articles on any subject connected with amateur science or work will be gladly received from any of our readers, and any suggestions offered will be duly considered. The Young Scientist was ushered into existence from a sincere desire to benefit and assist young people in the acquisition of scientific knowledge and mechanical expertness; and to this end we have made arrangements that enable us to assure our readers that there will be no paucity of articles in the forthcoming numbers on the following subjects: Astronomy, Natural History, Botany, Floriculture, Practical Mechanics, Decoration, Acoustics, Hydrostatics, Pneumatics, Heat, Light, Magnetism, Electricity, Gases, Matter, Force, Motion, Ornithology, Zoology, Entomology, Geology, Photography, Pyrotechnics, Paper Flower Making, Joinery, Cabinet-Making, Wood-Engraving, Wood-Carving, Modelling in Clay, Painting, Drawing, Etching, Painting on Glass, Experimental Chemistry, etc. Notwithstanding the fact that these arrangements have been made, we would prefer that our younger readers would write us their experience—trials, failures and successes—on the various studies they may be engaged in. Young people like to know of other young people's doings, and are more likely to be encouraged by the successes of their amateur contemporaries than by the successes of experts. Taking this view of the matter, we earnestly ask our readers to make known their experiences through our columns, not only for the benefit of their fellow-readers, but also for their own edification, a result which is sure to follow a careful analysis of their own doings.

There never was a time in the history of the world when so many able men evinced such a strong desire for progress and advancement as at present, and the old Latin proverb, "*Bos optat ephippia*," may now in truth be applied to the majority of those who toil with hand or brain; for the mechanic seeks to acquire the theoretical knowledge of the brain-worker, while the latter longs to be possessed of the manual skill of the former. The amateur and the skilled worker alike desire to know the why and wherefore; the one to gain a shorter road to excellence, and the other to assist his manual skill by technical knowledge, and thereby enable him to add to his earnings. On the other hand, the clerk, the banker, the student, and the man of letters, who may be well up in theory, and who know why this, that, and the other are, and should be done, and who can offer useful theoretical suggestions, feel a want of practical knowledge, and are therefore anxious to make themselves familiar with the various manipulations and operations as performed in the numerous trades. To these searchers after knowledge the Young Scientist offers special opportunities for finding what they seek, as the range of subjects discussed is extensive, and, in a measure, complete. That a journal of practical instruction in mechanical and scientific matters, adapted to the requirements of amateurs, is a popular want, there is more than sufficient evidence to show by the letters received at this office commending our "new departure," and

filled with words of encouragement and good wishes for our future success. We are thankful for these evidences of good-will, and shall, in the days to come, endeavor not only to retain the good opinion of our readers, but to increase its intensity and enlarge its area.

One of the greatest indications of the development of American mechanical genius rests on the fact that since the introduction of foot-power scroll-saws in 1874, no fewer than 250,000 of these machines have been made and sold, of various grades and prices, ranging from $2 for the wooden-frame saw, to $30, and even $40, for the more complete and perfect saw, with light iron frame and steel works. To supply these saws with blades would require something like 250,000,000, figures that seem enormous at first sight, but when we consider that each saw frame in use for a few years will use up several gross, owing to their liability to break, or become dull and worthless with little use, the number manufactured is simply amazing. A reporter who visited a dealer in saws, blades, designs, and fancy woods recently, was told that "there is an increasing interest in scroll-saw work, and judging from appearances and demand, there is no sign of the business slacking up." When asked if it was not possible that designs for sawing might be exhausted or become too intricate, he was told "that intricacy of design is no obstacle, but rather in favor of the business, as sawyers are becoming so expert that what a few years ago seemed impractical designs, from their intricacy, are now very ordinary affairs, and are cut almost daily by novices in the art. There are at least a dozen different designs for almost every subject you can think of—bird-cages, music-racks, writing-desks, picture-frames, work-boxes, shrines, cloak-cases, flower-pots, brackets and match-safes. These are not a tenth of the subjects. We sell, I should say, over 500 patterns a year, besides a number of scroll-sawyers' manuals." "Who does all this scroll-sawing?" asked the reporter. "Principally boys, although there are a great many business men who engage in it as a pastime. One of my customers is a married man, whose wife prepares his work for him during the day. Another was a high-school boy, whose sister did everything except to saw out the design. Then, again, ladies have been so infatuated with the work that they have done a great deal of it, especially the inlaying, which requires considerable skill." Many of the saws now in the market are models of constructive genius, being built so as to produce the best results with a minimum of materials, labor and expense. The more expensive saws have various attachments, such as circular saws, turning lathes, rotary moulders, boring machines, and inlaying appliances, all of which tend to give the machine more range and to enhance its value.

Astronomy for Amateurs.—May.

BY BERLIN H. WRIGHT.

TOTAL ECLIPSE OF THE SUN, MAY 6.

The Sun will be totally eclipsed on the 6th of May. The width of the path of totality of this eclipse will be unusually great, and the partial phase will be visible over a very great area; still, very few civilized people will behold it, as the favored region is in the Southern Pacific ocean. The savages will beat their tomtoms, and resort to their customary practices to propitiate their angered god, that he may cause

Fig. 1.—TOTAL SOLAR ECLIPSE.

the light of day to again appear. The path of totality extends from a point in the Pacific ocean off the west coast of South America, in lat. 12° south; long. 87° west of Greenwich, through the Marquesas Islands; thence through the Friendly Islands, passing north of the Paumotu, Society and Hervey Islands, and south of the Fiji and Loyalty Islands and New Caledonia, terminating upon the west in lat. 35° south; long. 157° east of Greenwich.

The northern line of limitation passes from near New Ireland, northeast of New Guinea, through the southern portion of the Marshall Group and the Sandwich Islands, touching the southern extremity of the peninsula of California, crossing Southern Mexico and Yucatan. A very small partial eclipse will be visible along

the coast of Peru, Ecuador and Colombia, and throughout Panama and Central America.

The most thickly populated portion of Australia will be favored with a very small eclipse just after sunrise, the limiting line (where the eclipse ends at sunrise) passing about midway between Adelaide and Melbourne. As the path of total eclipse passes over no favorable point, but little effort will be made to secure observations; still, one or two small expeditions have set out for some of the "South Sea Islands."

Inasmuch as the Moon moves from west to east in its orbit, its shadow must pass from west to east over the earth.

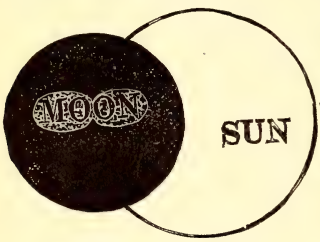

Fig. 2.

Fig. 3.

Fig. 4.

The Moon produces a total, partial or annular eclipse of the Sun whenever she passes within 17° of one of her nodes at the time of New Moon, and if this event occurs at the time of perigee, a total eclipse occurs, for then the Moon's umbra, which is only about 234,000 miles long, touches the earth. The nearer the Moon is to the earth the wider will be the belt of totality and the greater its duration, because the diameter of the umbra will be greater. If the Moon reaches her node exactly at the time of conjunction, i.e., directly in a line between the earth and Sun, at the time of Apogee, then an annular eclipse occurs, because the apparent diameter of the Moon is less than that of the Sun (see Fig. 4), and when at perigee, or nearest the earth, then the eclipse must be total, for then the apparent diameter of the Moon is equal to or exceeds that of the Sun. But when the conjunction occurs *near* the node, a partial eclipse must occur, cutting off (Figs. 2 and 5) only a portion of the Sun's limb. And the further from the node, inside of the solar ecliptic limit, 17°, on each side of the node, or 34°, the Moon is, the smaller will the eclipse be. The period occupied by the Moon in passing over this portion of her orbit may be called, for convenience sake, the eclipse season, which is of about twenty days duration. Fig. 5 represents the equator of the heavens, C D; the earth's path, F G, and the path described by the Moon's nodes, E H. It is evident that eclipses can only occur at a limited distance each side of A and B, the two nodes, or from *a* to *b* on each side of A.

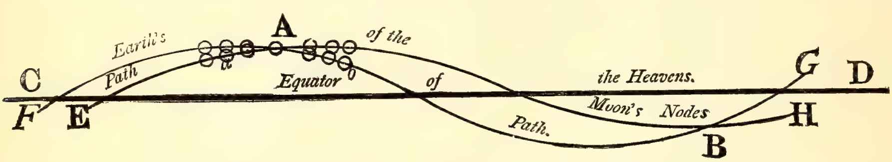

Fig. 5

It must be remembered, in this connection, that the *Sun's apparent* path through the heavens is the *earth's true* path.

THE PLANETS.—MAY, 1883.

(All Computations are for the Latitude and Meridian of New York City.)

MERCURY AND JUPITER.

These planets are evening stars, Mercury being the most western, Jupiter being about one hour or 15° east of Mercury. They set as follows:

MERCURY.

May 10—8h. 55m., 33° 16′ N. of west point, and 9° 40′ N. of sunset point.

May 15—9h. 2m., 33° 55′ N. of west point, and 7° 59′ N. of sunset point.

May 20—8h. 58m., 33° 29′ N. of west point, and 6° 38′ N. of sunset point.

JUPITER.

May 10—10h. 21m. eve.
" 20— 9h. 51m. "
" 30— 9h. 20m. "

The following are the only phenomena of interest, transpiring at a seasonable hour, that are visible:

Sat.	*D.*	*H.*	*M.*	*Phenomena.*
I.	5	8	13	Transit, ingress.
I.	6	8	43	Eclipse, reap.
IV.	7	8	2	Occult., disap.
IV.	7	9	45	Occult., reap.
II.	7	9	51	Transit, egress.
II.	16	8	29	Eclipse, reap.
III.	20	8	22	Occult, "
III.	20	8	22.1	Eclipse, disap.
I.	21	9	1	Transit, egress.
I.	28	8	45	" ingress.

It will be interesting to see Sat. III. appear from an occulation on the 20th, at 8.22 eve., and six seconds later plunge into Jupiter's shadow.

Saturn is too close to the Sun to be seen.

Venus and *Mars* approach within three-fourths of one degree of each other on the 10th, Venus being the most southern. They will be situated at that time exactly in the middle of the constellation Aquarius, with no stars brighter than of the fourth magnitude within 20° of them. The Moon passes about 4° north of them on the morning of the 4th. They rise as follows:

VENUS.	MARS.
May 10—3.32 morn.	May 10—3.29 morn.
" 20—3.21 "	" 20—3.8 "
" 30—3.11 "	" 30—2.56 "

Uranus passes the meridian on the 5th at 8.28 eve.; 25th, 7.9 eve.

EPHEMERIDES OF THE PRINCIPAL STARS AND CLUSTERS, MAY 22, 1883.

	H.	*M.*	
Alpha Andromeda (Alpheratz) rises	0	13	mor.
Omicron Ceti (Mira) variable, "	4	27	"
Beta Persei (Algol) " "	1	53	"
" " sets	8	8	eve.
Eta Tauri (Alcyone or Light of Pleiades) rises	4	13	mor.
Alpha Tauri (Aldebaran) rises	5	32	"
" " sets	7	26	eve.
Alpha Aurigæ (Capella) rises	3	0	mor.
" " sets	11	15	eve.
Beta Orionis (Rigel) invisible.			
Alpha Orionis (Betelguese) sets	8	13	"
Alpha Canis Majoris (Sirius or Dog Star) invisible.			
Alpha Canis Minoris (Procyon) sets	9	51	"
Alpha Leonis (Regulus) sets	0	48	mor.
Alpha Virginis (Spica) in merid.	9	18	eve.
Alpha Bootis (Arcturus) "	10	9	"
Alpha Scorpionis (Antares) in meridian	0	24	mor.
Alpha Lyrae (Vega) in meridian	2	35	"
Alpha Aquillae (Altair) rises	9	14	eve.
Alpha Cygni (Deneb) in meridian	4	39	mor.
Alpha Pisces Australis (Fomalhaut) rises	2	53	"

Penn Yan, Yates Co., N. Y.

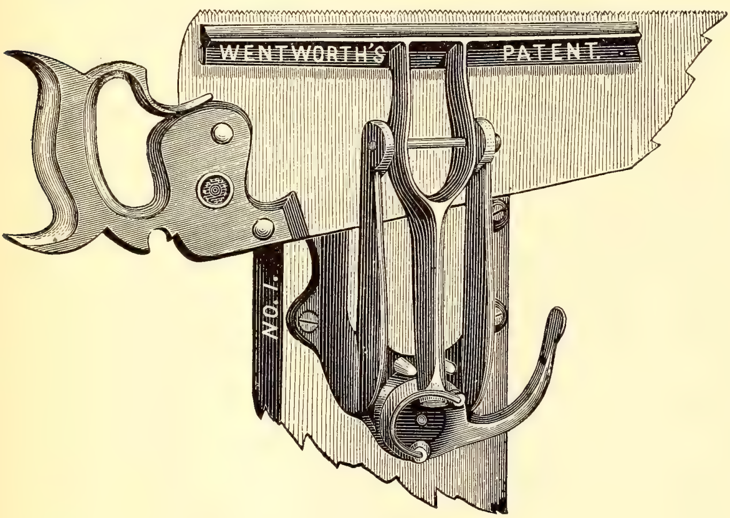
A Tailless Kite.

This is the time of kite-flying, and the boys are ready for any novelty that will add zest to the sport. A number of years ago some gentlemen of Rochester discovered in a book of designs printed in Holland a drawing of a kite which should float in the air without the necessity of a tail balance. One of the gentlemen constructed one, and when he displayed it to his incredulous friends they derided his assurances that there was go in it, and he would make it go. The first attempt was a failure. Indeed, if the kite doesn't rise on the first sufficient gust of wind, it should be discarded and a second kite made. The second attempt was a decided success, so much so that as the erratic thing cavorted beneath the empyrean everybody wondered what strange creature of the air it might be. Recently another one of these singular-looking flyers was put up, and it would have done one good to have seen how delighted the boys of twenty or thirty years old were as the tailless kite soared away into the blue depths, now plunging eccentrically towards contiguous dwellings and again gracefully swimming up towards the zenith. It is intimated that tailless kite-flying will be *the* popular amusement this season. For those who desire to try a hand at the novelty, we give brief directions as to construction. The shape of the kite is what the boys call "diamond." The cross-bar, which in a tail kite of the diamond pattern is straight, should be made of hickory and bowed by connecting the ends with a taut string. It should then be placed at right angles with the perpendicular stick and fastened securely, the bend of the bow being backward from the intersection of the sticks. Run a string around over the end of each stick, and cover the frame with light tissue-paper. For a four-foot kite, the perpendicular stick should extend three feet below the point of intersection with the bow, and one foot above it. The bow should be one and one-half feet long on each side of the point of intersection with the perpendicular stick. The belly cord should be united at the point of intersection, and at the same distance down the perpendicular stick as the arms of the bow extend on each side of the perpendicular stick. The band is attached at only two points, the point of intersection and at a point below, in the four-foot kite mentioned, one and one-half feet below the point of intersection. Tie these two strings together, and attach the captive cord, balancing it so that the captive cord shall be exactly opposite the point of intersection, or at right angles with the perpendicular stick frame. The face of the kite is then convex, and the back, of course, concave.

If at first you don't succeed, try again. It is a fun for all sorts of boys. This form of kite is sometimes very eccentric, and as game as a wily fish.

Novelties for Amateurs.

Among the new things we intend talking about this month is the new Wentworth saw-clamp, made by the Seneca Falls Manufacturing Company, Seneca Falls, N. Y. This is an excellent device for holding a saw while being filed, and is particularly adapted for the use of amateurs, as it is simple, durable, and easily handled. The saw can be placed in the grips or jaws almost instantaneously and as readily removed, and may be slipped forward or backwards in a moment, at the will of the operator. The annexed illustration exhibits the device, and will give the reader some idea of the working and character of the tool. In the cut the saw is shown in position, gripped tight and ready for filing. The clamp is attached to the side of a work-bench, table, or side of a wall below a window, by means of strong screws, and it may readily be taken away if not convenient to leave permanently in position.



The clamp is worked by means of a cam, to which a lever is attached, all of which is shown on the lower part of the cut. The cam attachment is convenient and handy to work, and is as efficient as it is simple.

To Transfer Printed Matter to Glass.

Flow the glass-plates with a good quality of photographers' negative varnish, which should be thinned down in the usual way. When this has been partially dried so that it will not run into the paper, lay the engraving or show-bill face downwards upon the prepared surface, and subject it to a slight and uniformly apportioned pressure for twenty-four hours. Then moisten the back of the paper, and by means of a soft rubber, rub off the softened paper. If this is done with care, the ink lines will remain attached to the varnished glass surface. As the thin varnish is quite transparent, this is equivalent to transferring the engraving to the glass surface. The transfer is frequently improved in appearance by giving the plate (and transfer) a second coat of varnish.

Scientific News.

—The reappearance of the Star of Bethlehem is predicted by astronomers for this year or the next. On the 11th of November, 1572, Tycho de Brahe discovered a star in Cassiopeia which equalled Sirius, and even Venus, in brightness for a month, and then fell back into its former insignificance. Conjecture has sought to establish a connection between this phenomenon and two similar apparitions in 1264 and 945. A not unnatural inference was that the same increase in volume of this remarkable star occurred before 945, which would bring us to about 630 and 310 and to the date of the Nativity. This star is now again due.

—Nothing can be worse for a child than to be frightened. The effects of the scare it is slow to recover from; they remain (sometimes) until maturity, as is shown by many instances of morbid sensitiveness and excessive nervousness. Not unfrequently fear is employed as a means of discipline. Children are controlled by being made to believe that something terrible will happen to them and punished by being shut up in dark rooms, or by being put in places they stand in dread of. No one without vivid memory of his own childhood, can comprehend how entirely cruel such things are. We have often heard grown persons tell of the suffering they have endured, as children, under like circumstances, and recount the irreparable injury which they

are sure they then received. No parent, no nurse, capable of alarming the young, is fitted for her position. Children, as nearly as possible, should be trained not to know the sense of fear, which, above everything else, is to be feared in their education, early and late.

—The records of industrial progress nowadays read not unlike what the English laureate once termed "fairy tales of science." There seem to be no limits to the transformations which material products undergo at the hands of the modern scientist. These remarks are suggested by the very suggestive title of a book lately published, "The History of a Lump of Coal from the Pit's Mouth to a Bonnet Ribbon." The alchemic power of science, even if it does not transmute whatever it touches into gold, yet, by means of judicious separations and combinations of elements formerly regarded as useless, can so increase the value of products that its effects fall little short of those dreamed of by the magicians of the Middle Ages. It is implied in what has been said above that the influence of scientific research upon industrial methods is growing more marked with each succeeding year. This state of affairs is now generally recognized and was alluded to by Dr. Siemens in his address as President of the British Association, who declared that the advancement of the last fifty years has rendered theory and practice so interdependent that an intimate union between them is a matter of absolute necessity for our future progress.

Notes and Queries.

In continuing this department, which has been found of so much value, we would remind our readers who wish for information on any of the arts and sciences, that they are cordially invited to make their wants known through this column, and those of them who can furnish accurate answers to questions asked are requested to send in replies. Doubtless many of our subscribers may know of methods, processes, or devices that may be better or more suitable for the particular case in question than anything generally known, and it is this reason that induces us to keep this department open for a medium, where an interchange of ideas and practices may be made to the advantage of all our readers. Correspondents will please send their full address when forwarding their communications—either questions or answers—not for publication, unless expressly so stated, but so that we may know where to find the writer if desirable. Communications should be sent in on or before the first of each month previous to publication, to insure insertion in next issue.

Answers.

57. Parlor Plants.—In reply to Ida, I beg leave to submit the following hints and suggestions:

In growing plants in the house we must first bear in mind that not every plant is suitable for such culture.

First, there is no better plant than *Abutilon striatum.* It grows freely, is not troubled by insects, and is always in bloom. The gaily-colored bells are very pretty.

Next, the Calla-Lily, so called, though not botanically a lily, will grow well and give a profusion of bloom. Give it plenty of pot room, let it grow very large, allowing all the suckers to remain, and give plenty of water. We have seen plants, thus treated, with a dozen flowers each.

Chinese Primroses are very easily grown and flower freely. They should have light, rich soil, and the pots should be well drained, for if the soil becomes sodden the plants never flourish.

Cyclamen do well with window culture. The soil should be rich, and the plants once started into growth should never suffer for want of moisture.

The Monthly and Sanguina Roses, so seldom seen now, are the best for the parlor; a very double rose fails to open its buds. Roses brought directly from the green-house to the parlor seldom do well.

The winter-blooming Fuchsias, *speciosa* and *serratifolia*, are capital window plants, and are always in bloom.

Daisies and Violets seldom do well in the parlor; the air is too hot and dry for them, and they are very subject to the attacks of green fly.

Of Geraniums the Zonale or Horseshoe varieties are the best. They give little bloom until after the short days, but when they once begin to flower are seldom out of bloom. The species with sweet-scented foliage are worth growing, but the flowers are insignificant.

Of Ferns, the best for the parlor is *Pteris tremula*, the next *Adiantum cuneatum.* These ferns will withstand both gas and furnace heat, and are always beautiful.

One great secret in growing plants well is to *water thoroughly.* Few plants, unless in a very dry position, need water every day; but when watered the soil should be saturated; the superfluous water should be allowed to drain off, for there is scarcely a plant (Calla-Lily excepting) that flourishes if water remains on the roots.

Attention should be given to washing the foliage, for a plant breathes through the leaves, and if the pores are stopped with dust the plant suffers.

The temperature of water used for plants should be that of the room in which they are growing—warmer if you please, but not colder. A plant is a living being; its wants are few, but careful attention to these is essential to its health and beauty.—Flora.

58. Cleaning Kid Gloves.—If Katie B. will try the following, I think she will be quite satisfied. For a temporary cleaning, when the gloves are required for use in a few minutes, the easiest way is to take a piece of white flannel, dip it in milk, rub over it a piece of white soap, and then with this rub the soiled parts of the gloves. The advantage of this process is that the gloves can be worn ten minutes after having been cleaned; but the disadvantage is that the threads of the seams remain dirty. Benzine is better in this respect, and makes everything about the glove perfectly clean, as it dissolves all greasy dirt. It may be used in the same way as the milk above described, or as is done by those who make kid-glove cleaning a regular business. The gloves are put into a large glass-stoppered bottle, and shaken up with the benzine; in a short time the benzine will have dissolved all the dirt, is poured off, the gloves wrung out and dried on a hot plate; otherwise they will for a long time afterward smell of the benzine. The benzine used for cleaning may be recovered again in a clean condition by distilling at a low heat.—Boston Girl.

59. Wood-Polishing.—"Big Boy" will not be able to do good work in polishing wood until he has had some practice in the matter. He should first try his hand on some prepared pieces of wood, and not attempt to finish constructed work until he is satisfied with the experiments. Walnut or similar woods are best finished with fine glass-paper, No. 0; then color linseed oil with alkanet root and rub into the wood, and afterward let it stand for a time until the oil has thoroughly soaked in; then proceed to fill the pores with a composition of plaster of Paris, three parts, tallow one, and a little red polish. This is to be thoroughly worked until it is mixed and becomes a crumbly mass. It can be rubbed into

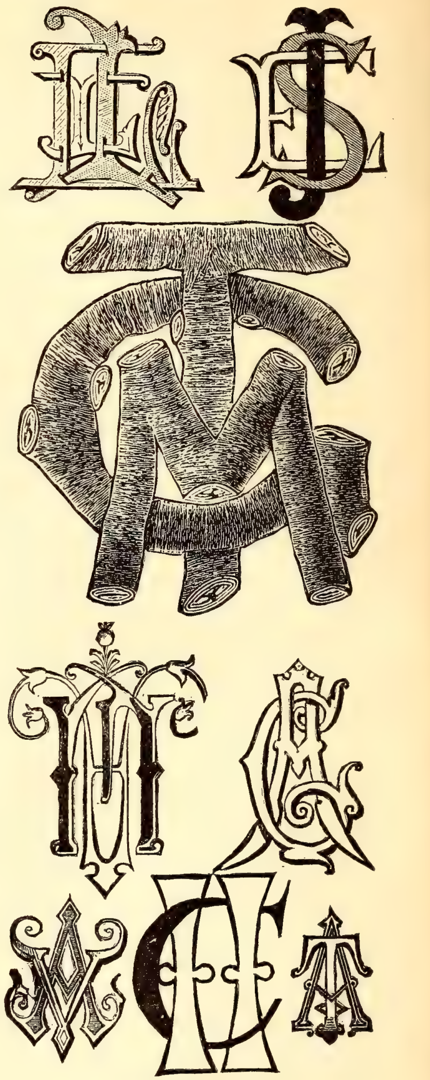
the wood with a piece of rag, after which all the superfluous parts are removed, and the surface is ready for the final polish, which may be put on with a brush, or after the French method—with a tampon; in the latter case only shellac dissolved in alcohol is used. With the brush you can use any kind of varnish. Soft woods may be turned so smooth as to require no other polish than that which can be given by holding fine shavings of the same wood against them in the lathe. For polishing mahogany, walnut, and some other woods, the following formula is given: Dissolve beeswax by heat in spirits of turpentine until the mixture becomes viscid. Apply with a clean cloth, and rub thoroughly with another flannel or cloth. Beeswax is sometimes alone used. For work in position, it must be melted and applied and rubbed as above. For work in the lathe, it can be applied by friction, the slight amount of wax melted being sufficient for the polish. The work should be thoroughly rubbed. Mahogany may be polished by rubbing first with linseed oil, and then by a cloth dipped in a very fine brick dust. Some hard woods have a natural polish, and do not require a polishing medium. A fine gloss can be produced by rubbing with linseed oil, and then holding shavings or turnings of the same material against the work in the lathe. A very perfect surface can be obtained with glass-paper, which, if followed by hard rubbing, will give a beautiful lustre. Lustre can also be given to carefully finished surfaces by applying a small quantity of thinned varnish, shellac or "fillers," by a cloth, and carefully and thoroughly rubbing. Part of the above is taken from "Comstock's Interior Details," and may be relied upon as being perfectly practicable.—Red Cedar.

60. Grindstone.—For turning up a grindstone the usual plan adopted by professional workmen is the following: Take a piece of sheet-iron, and secure it firmly upon the trough or frame (by hand or otherwise), close the grindstone. Let this one run gently towards the iron, which, of course, must be pushed on as it wears off. You will soon obtain, in more or less time, according to the state of the stone, a perfect, true, and level surface. If your grindstone is much out of true, you had better begin to bite the humps, by hollowing grooves with the sharp end of an old saw-file, secured as above.—"Our Ned."

61. Embroidered Monograms.—If Bella S. will give her correct initials, and state for what purpose she wants designs of monograms in embroidered work, I will, perhaps, be able to help her out somewhat, as I have a number of monograms suitable for needlework.—Lizzie.

62. Needle-Case.—In making a needle-case with shells procure a pair of the American fresh-water mussel shells *(Anadon fluviatilis)*, a full account of which may be found in the February number of the Young Scientist of 1881. See that the shells are the same size; perforate nine small holes round the front of the top one, at equal distances, about half an inch from the front, and two more at the top part of both shells. Take a narrow piece of sarcenet ribbon, put one end into the left hand hole and fasten it there, then over the front of the shell, under, and through the second hole, so on to the last, and fasten it off. Cut out two pieces of fine white flannel a little less, and also the form of the shell, bind it round with the same blue ribbon; put these inside, and with another piece tie them together through the four holes at the top in a neat little bow. For the strings in the front, take some more of the same blue ribbon, and, after fastening to each shell, tie together in a little larger bow.—X.

63. Monograms.—The annexed monograms of E. S. G., T. M. G., L. L. L., A. L. L., A. C., A. T., V. A., and C. H., have been received from various points. A number of other monograms have also been received from various parties, some of which were good enough to publish, but for which we cannot afford space in this issue, but may in future numbers.



Queries.

64. Oil Colors.—I desire to paint a few plaques in oil colors, the subjects to be flowers. Can you inform me where I can obtain designs or outlines for flowers, particularly of daisies? If you please, I would also like to know about the cost of same. —Katie B.

65. Steamboats.—Were steamboats ever patented? and if so, when?—"Big Boy."

66. The End of the World.—How many times has the "end of the world" been predicted by men of more or less weight? Are there any such doleful predictions hanging over us now?—Musical.

67. Painting Photographs.—Will you kindly inform me what colors are employed in painting photographs in water colors?—Thirza McB.

68. Glass.—Is it known that the Hebrews, when they first settled in Palestine, understood the manufacture and use of glass? Was the use of glass pretty well known among the ancients?—Curious.

69. Monograms.—Our readers who have the time and ability to construct monograms are invited to send in designs for the following combinations: G. B., M. D. H., L. F. R., E. H. H., W. A., W. W., M. G. T., and G. E. T. Contributors to this column are requested to send in their communications before the first of the month preceding the date of issue.

70. Aquaria.—Will some reader please inform me what fish and other animals and marine plants are best to start an aquarium with?—O. J. L., of Philadelphia.

Note.—Our correspondent is not very clear; he does not state whether he wants a sea-water or fresh-water aquarium. The following general suggestions are offered, however: We would advise about one bunch of plants to every three gallons of water, and three *small* fishes to each gallon of water. By a bunch of plants is meant such as is sold by the dealers. Valisneria is recommended above all other plants for the purpose; the rivers are full of this growth. Nitella, anacharis, and utricularia are also excellent plants for the purpose. In the matter of fish, try catfish preperel, shiners, dace, minnows, rockfish, sunfish, and tadpoles, all as small as can be obtained. Apply to Mr. Taxis, of your city, for further information; he is an expert in these matters, and you will find him a gentleman in every respect.

Market Report.

Retail Prices.

IMPORTED CAGE BIRDS.

Canaries, *Belgian*, per pair	$6.00 to 15.00
" *French*, per pair	6.00 to 15.00
" *German, Hartz Mts.*, each	2.50 to 10.00
Gold Finches, each	1.50
Gold Finch (mules), each	2.50 to 5.00
Bull Finches, not trained, each	2.50
Bull Finches, trained to sing two tunes, each	10.00 to 40.00
African Finches, per pair	2.50 to 5.00
Chaffinches, each	1.50
Talking Mino or Mina	10.00 to 25.00
Linnets, each	1.50 to 2.00
Linnets (mules), each	2.50 to 5.00
Green Linnets, each	1.50
Java Sparrows (blue), each	1.50
Java Sparrows (white), per pair	6.00 to 8.00
English Sparrows, per pair	1.00
Siskins, each	1.00
Gray Cardinal, each	4.00 to 5.00
Nightingales, each	8.00 to 25.00
Japanese Nightingales, each	5.00 to 10.00
Thrushes, each	5.00 to 7.00
Skylarks, each	5.00
Troopials, each	7.00 to 12.00
European blackbirds, each	5.00 to 7.00
Black-caps, each	4.00
Starlings, each	4.00 to 6.00

PARROTS.

Gray Parrot	10.00 to 15.00
Single Yellow-Head Parrot	8.00 to 12.00
Double Yellow-Head Parrot	10.00 to 15.00
West Indian "	4.00 to 5.00
Cockatoo (white)	18.00
Australian Shell Paraquets, per pair	6.00
"Love Birds," African Paraquets, per pair	6.00
West Indian Paraquets, per pair	3.00 to 5.00

All birds that are accomplished singers or talkers bring high and "fancy" prices. Parrots are rated by the number of words, sentences, and tunes they have learned.

AMERICAN CAGE BIRDS.

Canaries, each	2.50
Mocking Birds, females, each	1.00
" " singers	12.00 to 25.00
Robins	2.50 to 5.00
Blue Birds ("Blue Robins") each	1.50
Indigo Birds, each	1.00
Nonpariel, each	1.50 to 2.00
Virginia Cardinal, each	2.50 to 3.00
Bobolinks, each	1.50 to 2.00
Yellow Birds, each	1.50 to 2.00

Prices Paid by Dealers.

Robins, per hundred	12.00
Blue Robins (Blue-Birds), per pair	0.35
Indigo Birds, each	0.50
Bobolinks, per dozen	3.00
Yellow-Birds, per hundred	12.00
Orioles, per hundred	25.00 to 35.00
Virginia Cardinals (Red-Birds), each	0.75 to 1.00
Nonpareils, each	0.75
Blue-Jays, each	0.35
Scarlet Tanagers, each	1.00
Red-Winged Starlings, or Black-Birds, each	0.25
Woodpeckers ("High-Holers"), each	1.00
Partridges, each	1.50
Cranes, each (according to variety)	10.00 to 20.00
Wood-Ducks, per pair	2.50
Wild Bronze Turkeys (one cock, two hens)	10.00 to 15.00

FANCY POULTRY.

Guinea or Pea-Hens	12.00
Pheasants, *English*, per pair	20.00
" *Golden*, "	35.00
" *Silver*, "	30.00
Pea-Cocks, per pair	20.00 to 75.00
Bronze Wild Turkeys	15.00 to 20.00
White Turkeys	10.00 to 15.00
Bantams, trio	3.00 to 10.00
Ring-Doves, per pair	1.50
Pigeons, *common*, per pair	0.75
" *all white, common*, per pair	1.00

BIRD FANCIERS' MATERIALS.

Breeding Cages (double)	1.50 to 4.00
Trap Cages	0.75
Wire " painted	0.50 to 4.00
Wood and Wire Cages	1.50 to 4.00
Bird Lime, per box	0.25
Prepared Bird Food, per quart	0.30
Bird Gravel, per quart	0.05
Cuttle-Fish Bone, each	0.05
German Rape Seed, per quart	0.20
Canary Seed, per quart	0.20
Meal-Worms, per hundred	0.40
Nest Boxes, wire and tin	0.10 to 0.15
Nest Material, per bunch	0.10

QUADRUPEDS.

Terriers, *black and tan*, each	5.00 to 30.00
Terriers, *Scotch and Skye*, each	5.00 to 30.00
Newfoundland Pups, each	10.00 to 15.00
Pomeranian or Spitz "	5.00 to 15.00
Greyhounds, *English*, "	10.00 to 25.00
Greyounds, *Italian*, "	10.00 to 30.00
Guinea-Pigs, *common*, per pair	1.50
" " " " large	1.50 to 3.00
Guinea-Pigs, *all white*, "	2.00
Squirrels, *gray*, "	5.00
Squirrels, *all white* "	15.00 to 25.00
Squirrels, *flying* "	3.00 to 4.00
Squirrels, *small red* "	2.00
Rabbits, *common*, per pair	1.00 to 2.50
Rabbits, *fancy breed*, according to age and purity of breed, per pair	3.00 to 15.00
Ferrets, *English*, "	15.00
Raccoons, each	4.00 to 5.00
Cats, *Maltese* (males), each	5.00
" " (females), each	3.00

Cats, *Albinos, pink or blue eyes,* each	3.00 to 5.00
Rats, *white China, pink eyes,* per pair	1.50
Rats, *piebald,* per pair	1.50
Mice, *white, pink eyes,* per pair	0.50
Mice, *piebald,* per pair	0.50

Prices Paid for Pet Stock by Dealers.

Guinea-Pigs, per pair	$0.40
Squirrels, *gray,* each	0.50
Squirrels, *flying,* per pair	0.75
White mice, per pair	0.15
Monkeys, according to variety	15.00 up.

MARINE AQUARIA STOCK.

Purple Bermuda Anemone	2.00
Fringed Sea Anemone, Medium-sized specimens	1.50
White-Armed Anemone	0.50
Small Orange "	0.10
Buccinum Snails, per dozen	0.25
Silver Shrimp, each	0.10
Small Hermit Crabs, each	0.15
Small Spider Crabs (decorating)	0.15
Very Small Edible or Blue Crabs	0.20
Barnacles, each	0.15
Nest-Building Stickle-Backs, three and nine-spined, per pair	0.30
Sheepshead Lebia fish	0.25
Killie-Fish	0.10
Eels	0.10

Japanese King-gio	2.00	

Prices Paid by Dealers.

Aquarium fish, per hundred	1.50
Gold Fish, per hundred	5.00 to 6.00
Aquarium Plants, per hundred bunches	2.00

BEAUTIFUL AND INTERESTING AQUATIC AND SEMI-AQUATIC PLANTS FOR ORNAMENTATION OF PONDS, LAKES, AQUARIA AND FOUNTAINS.

White Water-Lily, per root	0.25
Yellow " "	0.25
Arrowhead Lily, 6 plants	0.25
Calla-Lilles	0.25
Pitcher-Plants, per root	0.25
Fresh-Water Cattails, per root	0.25
Giant Rush " "	0.25
Floating Heart (Limnantheum), per root	0.25
Calamus (sweet-flag), per root	0.25
Water-Cress, cuttings	0.25
Jack-in-the-Pulpit, 6 bulbs	0.25
Lobelia Cardinalis	0.25
Large, Showy Blue Lobelia	0.25
Water Violet (very curious)	0.25
Antipyretica Gigantia, interesting	0.25
" Fontinallis, interesting	0.25
The Water Net	0.25
Large Living Frogs	0.10

SHELLS.

Collections of small "cabinet" shells for schools, private cabinets, range from $5.00 to $50.00.

Mother-of-pearl shells, for painting, 75 cts. to $1.50.

Single specimens of cabinet shells range from 15 cts. each to $3.00.

Masses of corals, 25 cts. to $3.00.

Green snail and cowry, with the Lord's Prayer engraved on them, 50 cts. to $2.50 each.

Conch shells, for mantels or hearthstone ornaments: West India Conch, 25 cts.; East India Yellow Helmet, $1.00 to $2.50; Bahama Black Helmet, 50 cts. to $1.50; Bahama Hatchet Helmet, 50 cts. to $1.25. These shells are also for cameo engraving. Zanzibar Cameo, 25 cts. to $1.00.

Ground and polished shells: New Zealand Green Ear, 50 to 75 cts.; New Zealand White Ear, 50 to 75 cts.; Japan Black Ear, 50 cts. to $1.00; California Red Ear, 75 cts. to $1.25.

Fine shells for fancy work, according to colors and variety, per quart, $1.00 and up.

EXCHANGES.

"Crystallography" (40c.); "Electricity" (40c.); "Selection and Use of Microscope," abridged, (30c.) Either in exchange for "Workshop Companion," or two for "The Microscope," by Ross, or offers. C. H. Denniston, Pulteney, N. Y.

A printing-press, chase 5½ by 7 inches, in good order; will exchange for a large self-inking press or type. A. W. Barrett, Canajoharie, N. Y.

Home Medical Battery, cost $7; Lemair's Field-Glass, No. 2202 of Queen's Catalogue, cost $15.50; Achromatic Spy-Glass, power 25 times. To exchange for books or offers. Emerson Heilman, Heilmandale, Pa.

Silver watch, key-winder and Home Works, for good microscope or offers. Wm. Hodgson, 128 Mangin St., New York City.

A small collection of coleoptera, comprising 100 species and 300 specimens, all correctly named, in exchange for bird-skins, insects, books, or eggs. Emil Laurent, 621 Marshall St., Phila., Pa.

A small magic lantern, Ruby pattern, with twelve slides, for a good book on Entomology, with illustrations. Willie R. Hotchkiss, Morrisdale Mines, Clearfield Co., Pa.

Wanted, Thompson's "Witchery of Archery." Must be in good condition. Write before you send. J. Anthony, Jr., Coleta, Whiteside Co., Illinois.

A telescope worth $3.50, for a self-inking printing-press and outfit; chase not less than 2½ by 3½ in. Eddie Judd, 260 Connecticut St., Buffalo, N.Y.

To exchange for offers: $20 scroll-saw, Seneca Falls make, $4 Bailey circular plane, set of Auburn metallic planes, brass-bound four-foot rule, fourfold, Traut's patent combined plow, dado, etc., cost $7. F. A. Rappleye, P.O. Box 12, Farmer Village, Seneca Co., N.Y.

Bee Hive wanted; one of the old-fashioned straw "skeps"; say what you would like in exchange. Apis, care of Young Scientist, 49 Maiden Lane, N. Y.

A first-class type writer, in excellent condition, cost $125.00, to exchange for good microscope, telescope, or valuable scientific books; send full particulars. A. B., Box 114, Lewiston, Maine.

A $30 stencil outfit (Spencer's) for a self-inking printing press in good condition, chase about 6 x 9; rich ores and minerals of Idaho for scientific and instructive books, printing press, type, etc. J. P. Clough, Junction, Lemhi Co., Idaho.

Wanted pyrites of iron from Colorado gold mines in exchange for sea shells and other gems: send list of what you have to exchange. S. Ferguson, Eureka Springs, Arkansas.

A banjo in good condition, two pairs of rosewood bones, three splendid games, and a fine set of drawing instruments, for a good cornet, viola, violincello or double bass. L. B. Hill, Kalamazoo, Mich.

Casting in Plaster of Paris.—IV.

BY MARK MALLETT.

PIECE-MOULDS are made of plaster, but in sections so arranged that each piece can be pulled, without obstruction, from the cast. That they may thus 'leave' freely often necessitates that these sections should be very small and numerous. In making a piece-mould for a face, for instance, a dozen pieces or more will often have to be made.

A piece-mould cannot be taken direct from the clay model. A cast must first be made by means of a waste mould. This cast must, as a first step, be rubbed over with a little lard, which, on account of its whiteness, is better than oil or any other kind of grease, as it will not discolor the work. This is to keep cast and mould from sticking together. A little plaster must then be mixed, and the first section of the mould built up with the spatula on the cast. It will have to be made some three-quarters of an inch or more, according to circumstances.

When this piece has set, it can be pulled from the cast, its sides trimmed round with a knife, and lard must be rubbed over them. It must then be replaced, and two more pieces can be cast on two of its opposite sides, the outer edges of which will, in their turn, require paring and greasing, and the work can thus be carried on until the whole cast has been mapped out and covered with pieces larger or smaller, as the necessity for making them "leave" the surface freely may demand.

Lastly, an outer mould or shell, in two or more large pieces, to envelop and bind all the small pieces together, has to be made. Before the mould is filled these have, in their turn, to be bound and tied together with string. When this has been done—so closely will all the different pieces which have been cast one upon another, necessarily fit together—the

mould will seem as perfect and compact as if made of a single piece.

When such a mould is filled, a much thinner cast may be made then with a waste mould. A defect belonging to the piece-mould is that a little seam will show upon the cast wherever two pieces meet, and require cleaning away. A mould of this kind may be left for any length of time and filled repeatedly; but the seams will grow wider and more unsightly with use.

Piece-moulding is a delicate and tedious operation, and one that demands both skill and patience; its practice can scarcely be recommended to the amateur until he has had some practice in the working of plaster by the simpler methods.

Moulding from Marble.—For reproducing marble statuary in plaster, piece-moulding is usually employed, nor is there any material from which a piece-mould can be more readily taken. Instead of lard or oil, however, white curd soap only must be used on marble.

Casting from Nature.—Among the applications of the art of casting, none is more generally interesting than this. It is within the reach of the most indolent amateur, and will well repay him for bestowing a few odd hours upon it. To model a piece of good ornament, or still more, faithfully to portray the form or features of a friend, demands study and aptitude; but by means of casting, results somewhat similar may be borrowed direct from nature by any one. Let us begin with the human figure.

Though of course inferior in those qualities to the face, the human hand is full of character and expression. It is easy to recognize the hand of one with whom we are familiar. A cast of the hand is a pleasant memento, and few things can be easier than to make such a cast.

The sleeve of the person to be operated on should be rolled or twisted at the point where the cast is intended to be terminated. A little oil should be rubbed over the skin. As a cast showing one side of the hand will generally be all that is required, the mould can be made in a single piece. A soft pillow should be provided, a towel spread over it, and on that an old newspaper. With a little arrangement the pillow can be so made to accommodate itself to the form of the hand, and will so rise it as to leave no openings beneath; for if openings are left, the plaster will run into them, and there will then be a difficulty in getting the mould away. The mould can then be made in the usual manner. The hand must, of course, be kept *perfectly still* till the plaster has set, or the work will be spoiled; after it has set, it will be still of necessity till the mould has been removed. When the mould is finished the hand can be lifted from the pillow; the paper will prevent the plaster from sticking to the towel. Any little tongues of plaster which may have forced their way under the fingers can be cut away with the scraper, and the hand will be released without difficulty. When all is finished, and the mould clipped away, the operator can scarcely fail to be pleased with the results of his labors. Every fold of skin, and line, and marking, will be seen reproduced with the most microscopic fidelity.

Both sides may be moulded, if desired, and the hand reproduced in the round instead of in relief, by making a second half to the mould, according to the methods already described.

Not so easy is it to mould the face, or "mask," as a cast of the face is called, though this, when taken, is a thing of far higher value, for in no other way is so faithful a copy of the features obtained. The person whose face is to be operated upon should lie on his back, or sit with his head thrown backwards on a cushion. Towels should be placed over the hair and round the throat, to prevent the plaster running where it is not wanted. Whatever hair will necessarily come in contact with the plaster, as round the forehead, the eyebrows, moustache, beard, and whiskers, must be well plastered down with soap. Casting a mail mask is a matter of far greater difficulty in these days than it was in those of our fathers and grandfathers, when men went clean shaven. The hair and eyebrows are easily disposed of, but the beard and moustache are less tractable; and the novice is

rather advised to try his skill in the first place on a boy or a woman. A little soap or oil should be rubbed over the skin, and as the mouth will have to be kept close shut throughout the operation, quills or straws must be provided for insertion in

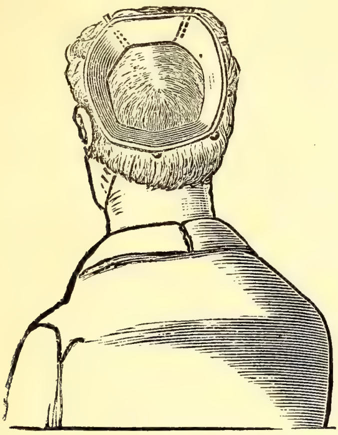

Fig. 4.—POT-LID IN MOULD FOR BUST.

the nostrils, that respiration may not be stopped. The plaster should be mixed with warm water. The sensation when liquid plaster is poured over the face is by no means an agreeable one, and this precaution will tend to the comfort of the patient; besides, as it will lessen the shock it will lessen the danger of any involuntary movement of the muscles of the face, and that these should remain rigid till the plaster has set, is essential to success.

During the ten minutes or so which must elapse before the mould is hard enough to be removed, the time will pass tediously for the person operated upon, and though there will be no real difficulty in taking it off, if the instructions given be carefully followed, some little pain may be occasioned; for any stray hairs which have become imbedded in the plaster will probably be pulled out, and will come off with it.

In a cast thus taken, the eyes will of course be closed, and the expression will be one of sleep. This is sometimes altered afterwards, if the person who takes the cast has some little skill in modelling, the eyes can be carved and made to appear open; and the remainder of the head and bust can be modelled to the mask from nature. But a work so treated is rarely satisfactory. It is really better and more valuable as a memento when kept as taken, and looks well if mounted on a slab of wood, covered with dark velvet.

Taking a mask in this manner after death, though a melancholy, is a much easier task. Under such circumstances no danger of failure is to be dreaded. That impatience on the one hand, and hurry on the other, which act as disturbing influences in casting from life, have not now to be taken into account. A mask taken after death forms a sad but precious memorial, and is an invaluable help to the modeller if a posthumous bust should ever be required.

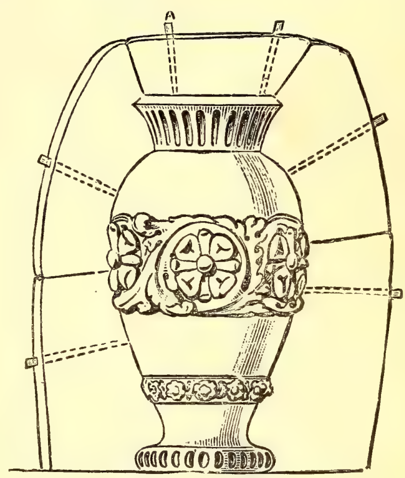

Fig. 5.

Such small animals as are cased in fur or feathers are difficult subjects for the caster, but fishes and reptiles are well adapted for his purposes. These lower organizations can, with little trouble, be arranged in life-like positions and moulded, a little oil being first brushed over them. Sand can either be packed beneath them, so as to allow the mould to be taken in one piece, or they can be half buried in that material, and their upper halves first moulded. They can then be

carefully lifted up, the sand cleaned away, the edge of the mould keyed and clay-watered, and the second half of the mould cast. By this means casts in the round will be obtained, and the plan is admirable for reproducing fishes or snakes, though not so easily applied to reptiles with feet, such as lizards.

Casts from animal life are often of scientific value for preserving the forms of remarkable specimens. They are frequently most useful, for reference, to the designer and carver in wood, stone, etc., or they may be made of service to those who work in metal or electrotype. A prettier, if not a more interesting department in the art of casting, is that which deals with vegetable forms, and chiefly with foliage. Leaves are admirable subjects, and easily dealt with.

If we take a single leaf and lay it on a table or flat board with a view to moulding, we shall at once see that it does not lie flat. It will touch only in two or three places. It is not the custom of nature to model her leaves in a single plane; she has so designed them that from whatever point of view we may regard them, they

Fig. 6.—QUARRY OF A DIAPER.

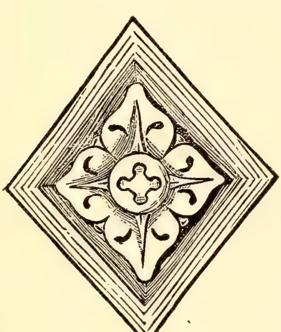

Fig. 7.—SECTION OF QUARRY FROM A TO B.

will present variety and beauty of curve. If therefore we desire to reproduce the leaf as nature has formed it, we must not flatten it, or allow it to be flattened by the weight of the plaster. We must find means of supporting it in its natural attitude. There are different methods of so fixing leaves, but none is simpler than to take sand, as advised in casting small animals. Spread a level surface of this on your table or board, and lay the leaf upon it. With the spatula it is easy so to pack sand beneath the leaf as to support it in every part. Leaves do not require preparing for moulding by either damping or oiling.

When the mould has set, it may be lifted from the sand, and the leaf will then be seen sticking to its under surface. Probably the plaster will in places have run in a little, and overlapped it. If so, such superfluous plaster may be carefully cut away with a pen-knife, after which the leaf can be peeled from the mould without difficulty; and the sand which adheres to the outer surface of the mould can also be brushed away.

As the mould is chipped off, the operator will indeed be hard to please if he is not both delighted and astonished with the effect of his work. He will see every serration, every vein and marking traced out with the most perfect delicacy in the pure white plaster, and will be struck with beauties of form and arrangement, which, when accompanied by their natural color, had wholly escaped his notice. By exercising a little judicious packing, fruits and berries can also be cast.

For the wood and stone carver, and indeed for all who practice the arts of decorative design, the importance of possessing casts from foliage cannot be overrated: in no other way can the designer so well have nature at hand for permanent reference. Such casts may also be applied direct to the purposes of decoration. For indoor uses, where plaster can be safely employed, casts from leaves and fruits, tastefully arranged, may be used for capitals, cornices, diapers, etc. In Fig. 8 a rough attempt has been made to show how such familiar leaves as those of the strawberry and gooseberry might in this manner be utilized in diaper as a wall decoration.

In this diagram only a simple arrangement of detached leaves has been shown, each enclosed in a sunk panel which may

be struck with the compasses, and cut out in plaster in a few minutes. But it is possible so to combine different leaves and fruits as to form most elaborate designs. In this latter case it will generally be better to cast each leaf, etc., separately, and afterwards to fit them in their places. If, however, the design when thus put together has to be repeated again and again in course of the decoration, a gelatine mould should of course be taken of the "repeat," copies of which will thus be quickly multiplied. In Fig. 8 two gelatine moulds are supposed to be employed.

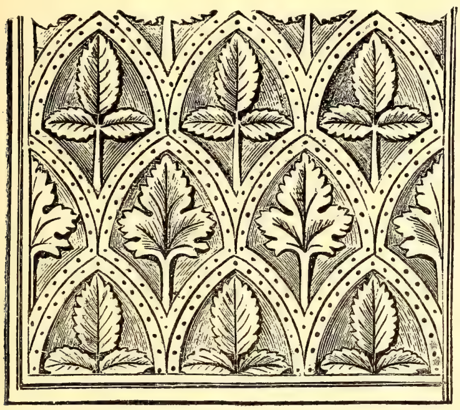

Fig. 8.—LEAVES IN DIAPER WORK AS WALL DECORATION.

It will thus be seen that casting from nature may by itself, and for its own sake, be considered an interesting art, and one worthy the attention of the amateur. The directions given for carrying out work of this kind for decorative purposes will, it is hoped, be of service to many to whom the utilization of natural objects in this manner has not hitherto suggested itself.

A Chat About Mitres.

In almost every piece of furniture that a cabinet-maker has to manufacture, one of the most important things to be done, after having framed the job together and got the " skeleton " finished, is to mitre in the mouldings, etc. To one unaccustomed to examining the detailed construction and manufacture of cabinet-work, the amount of mitering on any ordinary article of furniture such as a wardrobe would be truly astonishing. There are the mouldings to be mitered in the door frames, the mouldings, maybe, on the drawer fronts, the facings and mouldings on the cornice and plinth, and should the front of the job be broken by pilasters fixed on the doors, the mouldings of the cornice and plinth will have to be mitered round these also. Consequently there are a great many contrivances (some of which are purely local), known to most cabinet-makers, which are calculated to assist the workman, and remove some of the difficulties which mitering entails. Most of these, such as the mitre "cutting block," mitre "shooting board," etc., can be bought at any tool shop; but the one generally called the "mitre trap" cannot be bought at any tool manufacturers, and though well-known to the majority of workmen in the form of the finished article, the method of making such a tool is not so universally known. To many amateurs, therefore, a short description of how to make such a tool will, we trust, prove of service.

One form of mitre trap is shown in Fig. 1. It consists of three blocks, the

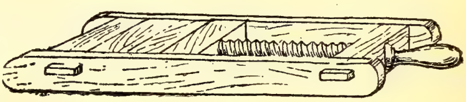

Fig. 1.

faces of two of them being cut at an angle of forty-five degrees, which work in a frame by means of a screw.

To make this tool, first get out the wood for the frame, which is separately shown by Fig. 2. The inside size will be about 18 inches by 8 inches. This frame will for appearance sake be mortised and tenoned together, although of course it would do quite as well if dovetailed. The two ends must be cut about 15 inches by 3

inches, and 1½ inch thick, and the two longer pieces 24 inches by 3 inches, and 1½ incn thick. As will be seen from Fig. 2, which is a front and end elevation of the frame, the tenons are left projecting over the front pieces about 2 inches, but only on one side. The use of this will be seen later on.

End View.

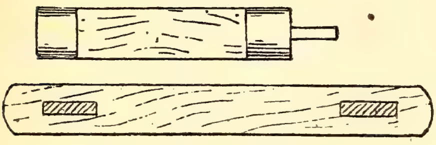

Fig. 2.—Front View

When this has been framed together "dry," that is, merely knocked together without being glued, and the projecting ends of the frame nicely rounded off, it must be laid on one side while the blocks are being prepared. The number of these latter is in a measure dependent on the will of the workman, as only two blocks are absolutely required, the mitre being cut by the wood being placed between. But as by the addition of one block the mitre trap may be used for "shooting" the ends of drawer fronts and such like, it will be much better to have three blocks. Cut these out, therefore, each 8 inches long by 3 inches square. After fitting these to the required length, so that they will work easily up and down in the frame, two of them are required for the mitre, a section of which is shown by Fig. 3. The other block must be left square. Now, take the frame to pieces, and work a couple of grooves along the inside of the two long sides, and across the end of the three blocks. Cut out and fit two tongues of hard wood into each of the grooves in the end of the blocks, which will now be of the appearance shown in Fig. 4.

The frame must now be glued together, the blocks being put in the order shown by Fig. 6, the grooves in the frame, and the tongues in the blocks allowing the blocks to move backwards and forwards in the frame. A screw must next be procured out of a piece of boxwood, and must measure about 16 inches in length, including the handle, and about 1 inch in diameter on the thread. In order to attach the end of the screw to the block, a plate of brass about 2 inches by 1 inch, must be fixed on to the end of the screw at A (Fig. 5), in such a manner that it will, when screwed on to the block marked B on Fig. 6, work the block backwards or forwards by simply turning the handle. The tool will now be of the shape shown in Fig. 6, which is a section cut right through the centre. To make a mitre, the wood must be placed between the blocks C and D, and then planed down to the level of the frame. To shoot a piece of wood square it must be placed between the blocks D and C. The best wood of which to make this tool is mahogany, though any hard wood will do. To fix it on the bench, place a holdfast on one of the projecting tenons, and screw firmly down.—*Builder and Wood-Worker.*

—When desperate ills demand a speedy cure, distrust is cowardice and prudence folly.

Something About Saws.—V.

BY "OUR NED."

SOMETIMES the amateur may have occasion to use and care for saws that are not intended for cutting wood; and when such is the case, he will find it to his advantage to possess some knowledge of the manner in which such saws are filed and used, and such other useful information about them that may be requisite. Doubtless every boy who reads the YOUNG SCIENTIST has noticed a tool hung up in his father's kitchen shaped something like the illustration shown at Fig. 1; and although he may have seen it often, unless he saw it used by the cook, he would probably never suspect its real mission. This is a butcher's saw, and its chief use is to sever bones, but unfortunately for the saw, when it gets into the kitchen it is made to do service for a half-dozen tools. It is frequently used by the "hired help" for cutting kindling-wood, and it often finds itself struggling "tooth and nail" with some tack or tenpenny nail that refuses to move from the path it is forced to follow, and there are instances where it has been known to do service as a hatchet.

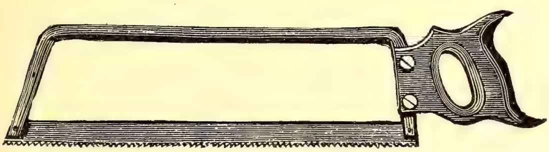

Fig. 1.

The form of teeth for this kind of a saw are shown at Fig. 2; they are equilateral,

Fig. 2.

which gives the pitch of the teeth an angle of forty-five degrees, front and back. To work nicely these saws should be well and truly jointed, filed square on front and back, and should have from twelve to eighteen teeth to the inch. Very little set is required in these saws.

The surgeon's saw—which may also be said to partake somewhat of a butcher's saw—is treated a little differently from the legitimate butcher's saw, though both of them are intended for cutting bones. This is owing to the fact that the human bone in a live person is not nearly so hard and brittle as the bones usually operated on by the ordinary butcher's saw. Being softer and somewhat porous, the living human bone requires a saw with a little more pitch, and a more acute bevel than is necessary for a butcher's saw, and it should be filed and jointed with the greatest care, every tooth being on a line, and jointed so that every tooth will be in a line on their side-cutting edges.

Fig. 3 shows the form of teeth adapted for these saws. It will be noticed that the form of teeth shown is something similar to teeth prepared for cutting hard wood. The number of teeth to the inch required for these may be from fourteen to twenty, according to the work required to be done.

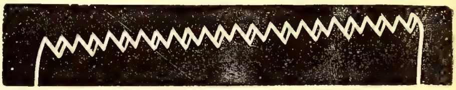

Fig. 3.

The next saw under notice will be the "hack-saw," or the blacksmith's saw, as it is sometimes called. This is used for cutting iron or brass. The blade should be hard, and the line of teeth perfectly straight.

Fig. 4 shows one of the better sort of

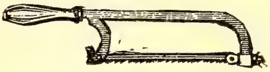

Fig. 4.

these saws. Like the butcher's saw and buck-saw, it comes in for a good deal of hard usage, but its character and vitality is such as to render it invincible, and though in many cases it would work better if cared for properly, it manages to perform its duties with a fair degree of satisfaction.

Fig. 5 shows the form of teeth suitable for these saws; they should be fine and filed square across, and the backs of the teeth should be filed square also. The teeth must be jointed all to one length and filed up to sharp points, and must stand square out on the edge of the blade.

Fig. 5.

It is better not to joint saws of this sort on the sides, as the edges left on the teeth by the file help the saw to cut the metal.

I have seen a piece of an old scythe do good service as a hack-saw, when the latter was not at hand. The edge of the scythe was nicked with a cold chisel, and then touched up with an old file, and the results obtained from using the impromptu saw were quite satisfactory. A hack-saw is simply a very thin file, with the cutting teeth all on one edge.

Brass, silver, zinc or gold may be easily cut with a hack-saw having fine teeth and a narrow blade, for inlay work or for metal ornaments. If the saw is adapted, it may be used in a foot-power scroll-saw, and, with patience, may be made to perform excellent work.

For cutting ivory, pearl, bone or shell, the teeth shown in Fig. 2 are the most suitable, but they require to be very fine and in good order.

Hack-saws, or metal-cutting saws for scroll or inlay work may be made from watch springs, and if the teeth are properly formed and made even and regular, they may be made to do good work. I have often made saws for cutting scroll-work in hard wood of watch springs, when I could not get the kind of saws I wanted without going to considerable trouble. When well made they will outlast anything that you can purchase, but they are very difficult to put in order when once they require it.

I think, from what I have said in the papers on the subject of saws, that the amateur who has followed me closely will be able to keep his saws in tolerable good order, and repair those belonging to neighbors who have not been so fortunate as to get the YOUNG SCIENTIST regularly. In a future paper I will endeavor to illustrate and describe some of the aids and appliances connected with amateur saws and their uses.

Amateur Boat-Building.—II.

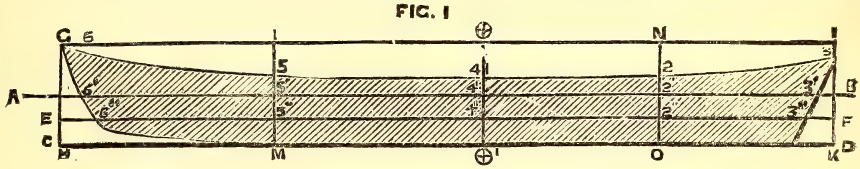
IN making a set of designs for a boat or a ship, the object proposed is analogous to that entertained in the preparation of drawings for a house or a steam-engine. This object is the representation on a plane surface of the thing to be constructed as viewed from at least three positions—or in elevation, in plan, and in section or sections. In the construction of vessels also, as in regard to the house or the engine, the preparatory drawings, must be made *to scale*, that is to say, that in all the set of designs a certain definite and unchanging proportion to the dimensions of the thing to be made shall be observed, as, for instance, one-eighth of an inch in the drawing shall stand for one inch in the boat or machine, or one inch in the former shall be equivalent to one foot in the latter, and so on. The larger, as a general rule, the scale upon which any working drawing is made, the better. In a shipbuilder's yard the lines of a projected vessel are frequently laid down on the floor of what is termed the "mould-loft," one-quarter, one-half, or even the full size of the vessel to be built.

For the purposes of our amateur boat-builder, however, a less ambitious scale will suffice, as very large drawings for his presumably small craft may be inconvenient. Speaking generally, a scale of one-eighth will be large enough. This has the further recommendation that, as the workman must provide himself with a rule on which the inches are divided into eighths and sixteenths, he can readily abstract his measurements therefrom. It is not advisable to adopt a less scale than one-eighth, however, and if the boat is not a long one it will be better to design it upon a scale of one-fourth the actual size of the proposed craft.

In the illustrations, Fig. 1 is the "sheer

plan," Fig. 2 the "cross-sections," and Fig. 3 the "water-lines" of the boat. The line A B in Fig. 1 represents the "load water-line," and indicates the depth of the boat's immersion when laden. The line C D, parallel with this load water-line, shows the draught of the boat, and a horizontal line, E F, is drawn equidistant from these two lines. The vertical line ⊕ ⊕′ corresponds with the broadest part of the projected boat, at what is called the midship frame. In nearly all drawings of marine architecture the symbol ⊕ (the same as that used in astronomical almanacs to designate the earth) is usually employed to denote this portion of a vessel. The midship frame is generally placed abaft (or behind) the exact centre of the boat, so that the part of the hull before it is longer than that portion behind it. The perpendiculars G H (at the bow) and I K (at the stern) are then drawn, and other perpendiculars, L M and N O, midway between the bow and the midship frame and that part of the boat and the stern.

FIG. 1



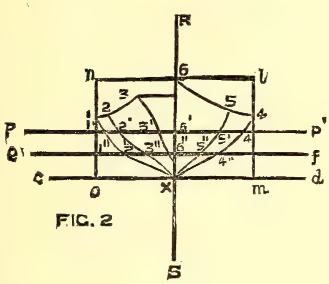


FIG. 2

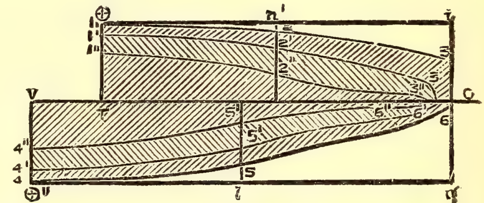

FIG. 3

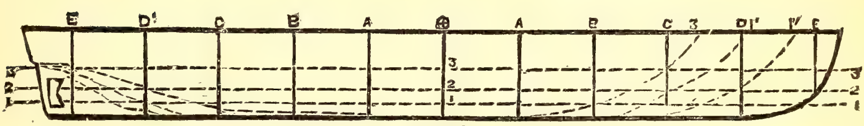

FIG. 4.

FIG. 5

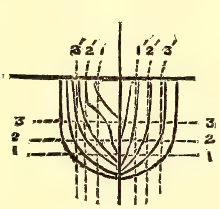

FIG. 7.

FIG. 6

Fig. 2 (showing the cross sections) and Fig. 3 are drawn on the horizontal lines P P′′ and Q Q′′ respectively. For Fig. 2 the horizontal line P P′ is bisected by the perpendicular R S, on each side of which the semi-breadth of the boat is set off at *n*, *o*, *l*, *m*. Here the line P P′ indicates the water-line shown by A B in the sheer plan; *c d* corresponds with the line of the greatest draught of the boat as at C D in Fig. 1,

and *e f* similarly occupies the place of E F in the same figure. The depth from *n* or *l* to the line P P′′ is that of the extreme height of the bow from the load water-line A B (Fig. 1).

For Fig. 3 the semi-breadth of beam is set off on each side of the line P′ Q, as at T ⊕, Q *i*, and V ⊕′′; Q *g* the distance, ⊕′ *i* being made equal to ⊕ I (Fig. 1), or the after part of the hull, and the distance ⊕′′ *g* being equivalent to that of ⊕ G (Fig. 1), or the fore part of the boat. The two lines *n*′ and *l*′, holding corresponding positions to N L (Fig. 1), are also drawn.

The designer is now able to fill in the cross-section lines and the water-lines of the craft. We may mention that the small figures as 1, 1′, and 1′′ indicate similar points in the three figures.

The shape of the boat itself (shown in Fig. 1 by the diagonal shading) is in the main dependent on the taste of the designer; but much care and discretion should be exercised on its careful proportionment and outline. That part above the load water-line is termed the free-board, and may differ considerably, according to the destination of the boat. It may be well to state that there is no necessity for shading the outline of the boat as in Fig. 1. It is only done in this instance to render our instructions more clear.

The lines 1′ 2′ 3′ and 4′ 5′ 6′ are now to be drawn on Fig. 3. These lines represent the load water-line A B (Fig. 1) for both ends of the boat.

The lines 1 1′ 1′′ X and 4 4′ 4′′ X in Fig. 2 are next put in, representing the midship section, and therefore necessarily having the same degree of curvature. This curvature depends upon the taste of the builder, except in so far as it is governed at the load water-line by the distances of the lines 1′ and 4′ on Fig. 3 from the line V Q.

In the cross-sections (Fig. 2) the lines 2 2′ 2′′ X and 5 5′ 5′′ X are next put in. These are shown on Fig. 3, at *n*′ and *l*′, and must be set off from the perpendicular R S (Fig. 2) on the line P P′ and equivalent distances at 2′ and 5′ to the same distance as 2′ and 5′ from the horizontal line V Q at Fig. 3, the remainder of the curve being a matter for the designer's taste and discretion. The line 3 3′ 3′′ for the stern is next drawn, and the cross-sections completed. It will be seen that the section to the left of the line R S is the after-part of the boat, and the portion to the right of that line is the forward half of the boat from amidships.

Fig. 3 may now be completed by the insertion of the remaining water-lines. We already have 1′ 2′ 3′ and 4′ 5′ 6′ for the load water-line. It is now necessary to put in 1′′ 2′′ 3′′ and 4′′ 5′′ 6′′, corresponding to the line E F on the sheer plan (Fig. 1), and the lines 1 2 3 and 4 5 6, corresponding to the line of the gunwale, as denoted by the same figures in the sheer plan.

It is thus clear that we have at Fig. 2 a series of vertical sections of our boat, and at Fig. 3 three horizontal sections of the same. If we imagine the boat cut into three flat slices by sawing it through at the two lines A B and E F (Fig. 1), we have the outlines of the planes given at Fig. 3. In order to render our meaning more plain, we have shown the plane of E F (Fig. 1) on Fig. 3 as filled in by shading diagonal lines sloping from right to left. In a similar manner the superfices at the load water-line A B (Fig. 1) is shown by lines slanting from right to left, while the length and breadth of the boat at the gunwale are denoted by vertical shading. It must be understood, however, that no such shading is needed in the regular working drawings.

Vessels of all kinds are designed in a very similar manner. Sometimes the section is termed the "body plan," and the plan of the water-lines the "half-breadth plan." Thus Fig. 4 shows the sheer plan of one of our large steamers, Figs. 5 and 6 the half-breadth plan of the same vessel, and Fig. 7 the sections or body plan. An inspection of these construction drawings may serve to render the foregoing remarks more easily understood. It will be seen that the straight load and other lines shown at 1, 2, 3 in the sheer plan become curves in Figs. 5 and 6, while, contrariwise, the lines 1′, 2′, 3′, which represent vertical planes, from the

deck of the vessel downwards, parallel with the keel, become curves in Fig. 4. In Fig. 7 both sets of lines appear as straight lines at right angles to each other. Of course in the actual construction drawings of a large vessel many more lines than are here shown are inserted; but we think sufficient has been said to show the principle involved, and to make it plain that the workman has in these three plans the exact position of each point of a vessel's exterior clearly indicated.

(To be Continued.)

Fried Ink-Pots.

BY A. W. ROBERTS.

FRIED ink-pots? Yes, "fried ink-pots;" fried in lard or olive oil, and mighty nice they are, too! Just as tender and sweet as fried scallops, which in flavor and texture they resemble very closely. Many and many is the ink-pot I've captured at night-time, and the darker the night the better luck one has, for it stands to reason that the glare from a jack-lamp or bull's-eye dark-lantern will have a stronger fascination over these uncanny-looking creatures on a pitch-dark night than on a moonlight or starlight night. Poor devils! (they belong to the devil fishes) they can't resist the temptation, the fascination of a glare of condensed light. They will swim right up to it, and into it, staring at it all the while with their unearthly, baneful-looking eyes. Then's the time to snake 'em in! All one has to do is to softly and slowly slide a long-handled and shallow scap-net under them; then quickly lift them into the boat and as quickly dispatch them with a few thrusts of a pen-knife, for if this precaution is not taken they will pump out and eject a black fluid from their funnels, which is called the ink. From this habit of ejecting an inky fluid they have been christened by the fishermen of Long Island "Ink-Pots." The fishermen of the Massachusetts coast have named them squid; naturalists, the *Loligo pallida.* I have concluded that for a common, popular, and well-fitting name, in pure and simple English, ink-pot is good. If some of the inky fluid is pricked into the skin, the same as in India-ink, it will produce a blue-colored tattoo, like India-ink, and it is said, on good authority, that the India-ink of the Chinese and Japanese is made from a similar substance, that is obtained from a variety of this fish, which is an inhabitant of the waters of

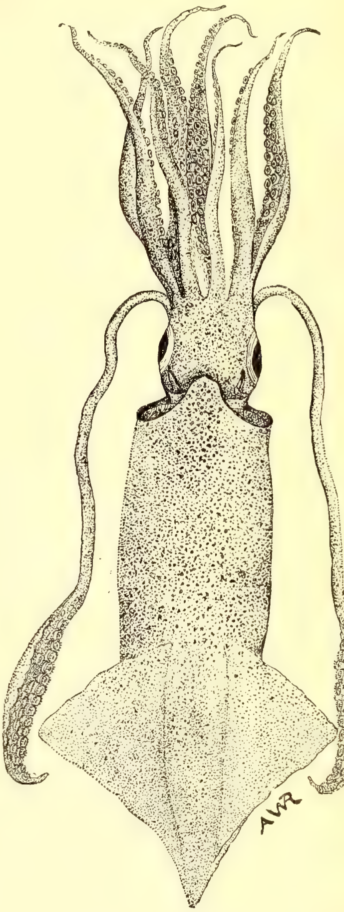

Fig. 1.

China and Japan. The same is the case with the coloring substance known as sepia, which is derived from the *Sepia apicinalis,* also a related variety of the *Loligo pallida.* The original sketch from which the engraving of the ink-pot (Fig. 1) was produced was drawn entirely with the ink that was taken from several of these strange inhabitants of the ocean.

After it was strained and evaporated, or, more strictly speaking, condensed, it was mixed with a small quantity of the spirits of ammonia and distilled water, after which it was thoroughly ground on a slab with a glass muller. When Nature provided this strange, grotesquely-shaped creature with a goodly supply of ink, it would seem as though she was mindful of the fact that he was not an expert swimmer, and as for turning short curves and corners that was an impossibility, but to give him a show to escape from his enemies, she provided him with this ink-supply, and right well he knows how to use it, for the instant his pursuers are closing on him, he lets go the ink which is stored up in his funnel with such force that in an instant it spreads out before in the form of an intense black cloud, so that while his pursuers are wondering what has burst, he beats a hasty retreat backwards through the ink-cloud, and down to the dark and deep waters of Mother Ocean. I strongly suspect that this inky fluid is very repugnant to fish, as they show a strong inclination to avoid it under all circumstances; perhaps it has a somewhat similar effect on fish that the thick and milky liquid which a toad will eject when attacked by a dog or cat, causing them to feel sick and of a retiring turn of mind. All the large kinds of free swimming and edible fish are passionately fond of the ink-pots, and why should they not be, for is he not a soft, sweet, and toothsome morsel? This being the case, he is in great demand as a bait for our game marine fishes, such as striped bass, sea bass, weak-fish, etc. By the mackerel fishers he is considered the very best of bait, when cut up into a fine hash. This hash is thrown broadcast over the water, till the mackerel are "chummed" together, after which an immensely long net is run around them, and they are prisoners. The squid, by which name it is known in our markets, always brings a high price, as a favorite fish-bait. Don't make the mistake of thinking that fish are the only creatures that like and eat this odd-looking, and to very many, repulsive-looking creature, for such is not the case, as the Chinese, Japanese, Portuguese, Spaniards, and French are all excessively fond of Mr. Ink-Pot, and pay high prices for him. The Portuguese and Spanish cooks are very particular when purchasing this fish that he contain a fair quantity of the ink, from which, when combined with wine, a dressing or sauce is made, that is anything but inviting-looking, as far as color goes, but to the taste is really enjoyable. I have known the squid to bring as high as from 75 cents to $1.00 per pound retail, and hard to obtain at those prices. I stated that this fish was destitute of any bony structure; perhaps that was hardly correct, for it is provided with a curiously-shaped bone, which in form strongly resembles a quill-pen, from which fact it has been called the "pen" (Fig. 2). This pen is transparent and flexible; the material closely resembles that of a goose-quill. The well-known "cuttle-fish bone" used by bird fanciers is also a product of a fish closely related to this fish. During the spring months immense quantities of the eggs of the ink-pot are cast upon the southern shores of Long Island. These are so puzzling to the ordinary investigator that after many attempts to determine their nature, he concludes that they are one of the strange, unfathomable mysteries of the ocean. These egg masses, when first exhuded, are not more than one-third of the size and weight of the squid; but after being in the water a few hours they swell to more than ten times the size of the parent. When a youngster it was a great mystery to me how frogs and ink-pots managed to deposit masses of eggs which were, in size, often ten times larger than themselves. To convey a clear idea of the egg clusters of the ink-pot I have made a pen sketch, Fig. 3. These eggs are very easy to develop if one has even a very small aquaria or a tub full of good salt water. To do

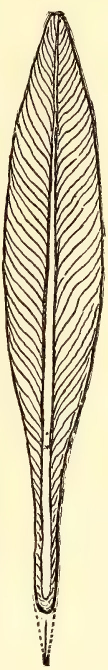

Fig. 2.

this eggs should be selected that contain well-developed or advanced (often living) minute ink-pots; this can be easily done by means of a powerful pocket-lens. The young ink-pots, when placed under a microscope, are wonderfully beautiful objects, showing both the blood circulation and the circulation and constantly changing of colors through the pigment cells.

Fig. 3.

The squid moves by taking water into the hollow funnel or body and ejecting it again with great force. This moves the squid backwards through the water with great speed and in short, jerking reaches. One of the curious features of this fish is the great number of sucking disks that are distributed in rows on the short and long arms. Each disk consists of a short and thick cylinder, the center of which can be raised so as to establish a vacuum between itself and the part to which it adheres. The sucking power of a medium-sized squid for its size is very great. The food of the squid consists of fish and small crustaceans. They have often been observed at Cape Cod capturing the fry of the mackerel, their method of taking so nervous, shy, and rapid-moving a fish being very interesting. Immense numbers of the squid would approach the shallow water at low tide, and laying flat on the bottom, their bodies assuming the color of the sand on which they were resting, they would wait patiently till a school of young mackerel passed over them, when instantly the long claspers or feeding arms would be shot upwards and a young mackerel would be seen to disappear. After the long arms had conveyed the fish beneath the water, the shorter arms, with their hundreds of sucking disks, would entangle the fish in their grasp and convey it to the mouth of the squid, which, being provided with two powerful jaws resembling a parrot's beak, was soon devoured, bones and all.

Overglaze Painting on Porcelain.—II.

BY AURELIO DE VEGA.

SOFT PORCELAIN.—It will be more convenient to notice next the soft porcelain. This is a French make. The principal portion of the body is practically a glass. The vitrifying materials (sand or flint, gypsum, and saline and alkaline ingredients) are fritted, that is, melted, cooled, and pulverized, and then mixed with the infusible body which is a white marl. The proportions being three parts of the former to one of the latter, the softness of the ware is at once recognized. It is principally used for statuettes, vases, and such like articles.

The most perfect examples of this kind of ware are found in the old Sevres ware, which is now imitated pretty successfully in many establishments at home and abroad.

(c.) *English Porcelain.*—The English porcelain differs from the hard in the introduction into the body of a large proportion of calcined bones, the effect of which is to render it better able to resist great heat and sudden changes of temperatures, and to give it a place as regards hardness between the other two kinds. Three descriptions are made—one for ordinary table use, one more delicate for dessert and the better tea-services, and the third, somewhat softer, for *objets d'art.*

The innovation which gave character to this ware was the work of Josiah Spode, who succeeded his father in 1797, and since it was generally accepted by the English makers, similar ware has been regularly made in our factories.

(7.) *Glazes,—(a) Hard.*—As with the wares so with the glazes, there is great variety. The hard porcelain admits of no metallic constituent in its glaze, which is composed solely of ground felspar or "crockery stone," with sometimes an addition of gypsum. These materials require for their perfect vitrification a very high heat, or, as it is called, a *hard fire,* and the glaze is therefore exceedingly hard.

(b.) *Soft.* The glaze for the soft ware is a specially prepared glass of the crystal kind, containing about two-fifth parts of lead oxide. Incipient fusion takes place, therefore, at a comparatively very low temperature.

(c.) *English.*—The English glaze, like the English ware, occupies a middle place. It is so far like the hard that it

contains a large proportion of felspar, but like the soft it contains lead. In this case, however, the metallic element is only about one-fifth of the whole. From the artist's point of view the approximation must be regarded as inclining towards the soft rather than towards the hard.

8. *General Test for Hardness.*—To complete the differences which we have now noticed in our goods, it is only necessary to add that the soft ware is, as a rule, of a slightly dingy and yellowish tint, and is more transparent than the other kinds, and that the glaze may easily be scratched with the point of a penknife. A very practical test is that boiling water heat when suddenly applied is generally sufficient to crack it, but this I fancy will be seldom tried.

9. *Effect of the Glaze upon the Painting.* We are now in a position to form an opinion as to the extent of the influence which any particular glaze will have upon the appearance of the work done upon it. It follows, from what has been said, that the harder the ware and its glaze, the more superficial is the latter; while the softer the ware and the more like it its glaze, the more complete and intimate is the incorporation of the two.

What to Undertake.—If, however, the work be, strictly speaking, only *attached* to the ware, in that of the soft the flux is practically *a continuation of the glaze.* The mode in which these conditions operate upon the painting is immediately obvious when it is stated that the pigments are of a vitreous nature or are mixed with a vitreous vehicle. The harder the glaze, the more superficial and less glossy is the painting; the softer and thicker the glaze, the more deeply does the color sink into it. I have an old Augustan (Dresden) cup and saucer, one of the colors employed in the decoration of which has absolutely no union with the underlying glaze, and is secured only by its connection with the color surrounding it. It has properly vitrified, but has not become incorporated with the hard glaze which appears in some spots where the color has chipped off. Compare such a work as this with a painting executed upon a piece of old Sevres, and how striking is the difference in the appearance of the two. In the former the colors are in large part hard in appearance and dryish, and generally lack that full and perfect gloss to be found on the latter, which presents a velvety softness of look. The reason is clear. The degree of heat adapted to reduce the pigments to a proper state of fusion is insufficient to affect the hard glaze to a corresponding extent, and the paint remains on the surface and looks more or less *dry.* If the glaze is sufficiently hard some colors may altogether fail to adhere, and the work of the painter, who by mistake has selected a piece with such a glaze, be entirely thrown away. The softer glaze, on the other hand, yields to the heat sufficient to vitrify the pigments, and so these sink more or less deeply into the body of the glaze, thereby acquiring that peculiar depth and richness of tone, which have given such charm and value to the old English and French wares. This very peculiarity, however, limits its range of usefulness, as it is only suitable for certain kinds of decoration in which rich and very showy colors are required to be used pure. The American glaze, from the middle position which it occupies, possesses most of the advantages of the soft, and practically none of its disadvantages, and while but little less suited than the latter for the particular work just indicated, is best adapted for every other kind of work, and is therefore to the painter an invaluable description.

10. *Scope of the Amateur's Work.—Special Position of the Amateur.*—Having thus dealt somewhat fully with the special characteristics of the different kinds of wares, and of their glazes, and also noticed the effect of those glazes on the work, it will perhaps be well to say a word or two upon a subject with regard to which much apprehension exists. This is the nature of the work which an amateur may advantageously undertake. It is popularly supposed that because a person does certain work himself, the result is the cheaper by the cost of the labor of whoever would otherwise do it. This is not always the case, and in nothing is it less so than in certain branches of china-painting.

The productions of the ordinary painter, whose wages are low, are in the style of the $10 dessert service, "ornamented with every variety of fruit and flower, magnificently painted by hand," as the advertisements read. Such a man is very useful in his way. In certain lines, indeed, such as call for rapid production and regularity, he cannot well be dispensed with, but with work which demands special artistic ability it is otherwise; the high-pressure rate at which he works precludes the possibility of his improving upon the peculiar style referred to, and that is scarcely, I think, the style which we should like to see exemplified upon our walls or our furniture, or in an article which we would offer as, say, a birthday gift, or a present in token of friendship or gratitude. From him we go by a step to the pottery-artist; but his work is really good, and being, as a rule, expensive, is within the reach of comparatively few. Now it may be presumed that the general amateur enters upon the study of china-painting, primarily with the view

of affording pleasure to himself, and his friends and relations, and herein lies his great strength and the advantage of his position, for he can leisurely devote his energy to the attainment of excellence in any special line for which he has aptitude, and so may develop therein an individuality from which his work may acquire a high intrinsic value in addition to the estimation in which, if it becomes a gift, it may be held from its associations.

Where the design is intricate—other than mere repetition of detail—or fanciful, or of such a nature that the time which would be occupied upon it by the pottery-artist, and by the amateur who has achieved some facility in the use of his brush and colors, would be about the same, or generally of strictly limited interest, the advantages are altogether on the side of the latter, whose taste and fancy may be exercised on objects of the greatest variety. Among the pieces to be had are spill-vases, flower-vases, flower-pots, breakfast-cups and saucers; especially, if I may make a suggestion to some fair student, moustache-cups, often most acceptable to the recipient; dessert and tea-services in which the decoration is elaborate, or contains much miniature or variegated gold work, afternoon tea sets, plaques of various shapes, round, oval, oblong, or square, and suitable for pictures for wall decoration, such as scenery, or family portraits, for covers for albums, for inlaying in clocks and cabinets, or for setting as brooches or in bracelets, dishes for the wall or for setting as card trays, dress buttons, solitaires, etc., etc. These, and the paintings on them, might be all objects of special interest; and the articles named are only a few of those which the amateur may decorate with most advantage.

11. *Principle of Selection.*—These considerations reveal the principle which should guide the amateur in selecting his work, if he would not be at a loss both of time and of money. He must emulate the true artist, not the mere painter. He must engage in work which appeals to his head as well as to his hand, not in what is only routine or mechanical.

What to Avoid.—At the pottery there is opportunity for the greatest economy in the use of paint, and every convenience is at hand for firing the painted article with the least delay, as often as may be necessary, and at the smallest expense. Hence, in the painting of a tea, coffee, chocolate, dinner, dessert, or toilet-service, which may have to be fired more than once, and which consists of several pieces, the decoration of each of which may be after a set design of whatever kind, it will be found that the work can be done better, more cheaply and more quickly at the factory, than at home—the standard of work being of course regulated by the cost.

(To be continued.)

An "Arrangement in Brown Paper."

Suggestions for Inexpensive Framing for Prints and Etchings.

BY J. W. GLEESON-WHITE.

DURING a past dispute between two men of light and learning, concerning the merits and demerits of certain harmonies in blue and silver, and arrangements in grey, a brochure was issued in defence of his works by the artist who considered himself insulted, clad in covers of homely brown paper, which was happily nicknamed by the phrase I have taken for my title—one which, from its utter lack of any definite hint of the subject, may be, to an ordinary mind, in keeping with the first cause of the pamphlet itself.

But the arrangement here to be talked over and suggested (though by chance first applied by myself to a charming etching by Whistler) has no other connection with the *cause celebre* than a vague trace of the picturesque, and refers to a somewhat novel application of an old rough and ready way of framing pictures that has often been used before, but hitherto chiefly in connection with very common and small articles, pictures only by courtesy, proving, however, capable of a different treatment, and admired by many artists and art lovers; it has been also (sincerest flattery) imitated by nearly every person who has seen it, that to the many who now may first make acquaintance with it, it will, I hope, prove acceptable from its two great merits—cheapness and simplicity.

In almost every home now one finds prints, etchings, pencil drawings, or photographs, sometimes issued with a popular periodical, or reminiscences of travel that are, while not quite worth framing, yet too good, or with too pleasant associations to destroy. These linger on, having no definite place, never to be found when required, and helping rather to litter than beautify the house, until they ultimately disappear in that mysterious visitation, known familiarly as the "spring cleaning," when so many valuable treasures swiftly and suddenly vanish away, and never are heard of again. If these forlorn pictures were once framed or kept with the intention to do so at a quiet time, not only would they be spared the sad end to which I have referred, but the habit of taking care of them once formed, would lead to the finding and saving many other suitable subjects. It is astonishing how any idea once adopted

finds unexpected possibilities arising out of the ordinary events hitherto unnoticed, and until one begins collecting any object, it seems that there must have been less of it in the world, by the sudden appearance in hitherto unsuspected quarters, of desirable and very often easily procurable specimens.

But without further preamble it will be best to explain the proposed method. Take an ordinary drawing, or print, or photograph. Mount the picture with ordinary paste on a piece of smooth cardboard. Any color, plain or printed, will do if it has only a fair surface, and enough thickness to withstand the warping; let this cardboard be the size of the print (that is, the actual black and white picture, regardless of the margin it possessed in its first state) with an outer margin of equal width all round. In "Touched," the print itself is $5\frac{3}{4}$ by $7\frac{3}{4}$ inches, allow a clear 3 inches each side, making the size of the mount $11\frac{3}{4}$ by $13\frac{3}{4}$ inches, paste the picture (without cutting off the old margin, as it may be useful for references and will be hidden) in the exact centre. Then take a piece of the grey mottled cardboard, now so much used and so easily obtained, cut from the centre a piece either $5\frac{3}{4}$ by $7\frac{3}{4}$, or $6\frac{1}{4}$ by $8\frac{1}{4}$ inches at will. Some prefer the grey mount to touch the picture everywhere, others like a narrow white border with the name of the artist, etc., showing. This is, I think, only to be decided by the character of the drawing, as some are much improved by allowing no other white than that left in the drawing to destroy the value of the tones of the picture itself. Having cut the grey mount, take a piece of rough cardboard, the top of a paper box or other available material, cut it $11\frac{3}{4}$ by $13\frac{3}{4}$, and at the distance of $\frac{3}{4}$ inch below the top, and say $3\frac{1}{2}$ inches from either side, cut two short upright slits with a sharp penknife, and pass a piece of narrow tape through them; this will lie flat on the surface, and should be tied behind in a knot close to one of the slits, so that a firm and unobtrusive support is left to suspend the picture when complete. Then having procured a piece of glass $11\frac{3}{4}$ by $13\frac{3}{4}$ inches, the size of these three pieces of board, lay the cardboard flat on a table, above that place the mounted etching, then over that the cut-out mount, and the glass above all. Next cut some thick brown paper into strips of about an inch or inch-and-half wide; thoroughly paste these and bind the four thicknesses together, the brown paper showing about half an inch all round in the front, and well over the back, being cut in mitre fashion at the angles. When dry it will be ready to hang; and, after cleaning off any paste-marks from the glass, will be found a very pleasing little picture, unpretentious in appearance, the framing being not unlike a plain oak frame at a distance, and an ornament, or at least no disfigurement in itself, apart from the actual etching, in any room it may find itself.

Pictures so treated would be useful not only for the owner's house, but (as I have found) find a very ready and profitable sale at bazaars, and make inexpensive and much-liked gifts for friends; moreover, they also find a warm welcome in the homes of the poor, as any visitor to them knows that a love for pictures, amounting almost to a passion, exists among the most squalid and unlovely surroundings.

The cost of the etching, "Touched," is twenty-five cents, the glass at most twelve cents, the cardboard perhaps five or six cents; so that for little more than thirty-five cents a really beautiful picture may be bought, framed, and hung on any wall. Contrast this with the price for the commonest "Dutch" metal frame, or the once all-popular "Oxford" one, and it will be seen that it is barely half the cost of the frame itself, not counting the print, while the art-beauty of the one is beyond comparison, as a little print in gilt frame is more or less an eyesore anywhere, while this simple substitute is sure to find favor with all or nearly all; and for those who dislike it, I was going to say, so much the worse for their taste, but remembering in time that abuse is no argument, and as a disciple of the "higher culture" (for who, writing under such a heading, could forget the necessity of living up to it?) it is only in keeping to ignore and refuse to allow even the possibility of the other side of the matter—certainly, if monotonously insisting that the "pictchaw is beautiful" be what will be said against it.

But this does not exhaust the possibilities of brown paper. Another way is worth noting. If the old gilded moulding, fly-specked and tarnishing, is well reclothed with brown paper, soaked with paste and well stuck on, so that it shows every feature of the moulding, it gives a very presentable appearance. The paper should be pasted some few minutes before use, and thoroughly moulded on to the wood. Each hollow and fillet will be seen sharply defined, and the whole will dry hard, and, while unlike paper, look somewhat like oak, and present a certain fresh character of its own, not attainable in any other way. In this case the brown paper itself is a pleasant variety to the grey mottled card for the cut-out mount and an ideal setting to many wood engravings, as it gives such value to the blacks and whites of the print, in the same way that a good photograph gains by a dark, dull mount.

A more ornate way of adapting the same idea would be to add to the binding of brown paper a strip of plush or velvet entirely hiding it, and put on after the paper is dry with a touch of glue or bind-all along each edge of the brown paper, the velvet or plush being put on when the adhesive substance is nearly dry or "tacky," as it is technically called. For some subjects the velvet margin might be wider, and touch the line of the drawing or photograph itself with good effect.

To those who live in our larger towns a constant opportunity of picking up suitable engravings presents itself, as almost any old bookstall has some part of an illustrated magazine or frontispiece of an old and valueless book that is well worth securing and utilizing in the way suggested. It may not be an early Durer, a noted Rembrandt, or a Meryan in a fine state, that is to be found; but pictures less valuable, in a money if not an art sense, may often be met with. I came across a copy of Flaxman's "Eight Illustrations to the Lord's Prayer" (an early set), for a few cents; and a nice Bartolozzi or bits of Claude's "Liber Studiorum" are often to be bought (out of the common run of tourists), very cheaply.

And now, in concluding this article, as I run my eye over it and wonder if I have not said too much in praise of my idea, I look up and see a long, low gallery, hung with a greenish-grey paper, with here and there a shelf of blue and white pottery or a few Dutch tiles catching the light. I see that half its charm lies in the pictures that I have framed in the "simple brown paper," and feel that "The Sappho," "Sunflowers" and "Quiet Counsellors" of Tadema, Arthur Moore's "Pansies," Leighton's "Daphnephoria," Burne-Jones's "Studies," and a Meryan ("Notre Dame"), are a true source of beauty and pleasure; for that, if it had entailed the cost of some thirty frames of even the simplest sort of wood, would have been sadly but of necessity foregone; and so with the proof positive so near, I offer no apologies for my much-lauded method, but hope that many a reader of this will follow the example, and thank me inwardly for suggesting this "Arrangement in Brown Paper."

"A New Boy."

BY AN OLD BOY.

THERE is a real and an undeniable awkwardness in most new positions, but of all new positions, that of the "new boy" in a public school is probably the worst. A lad fresh from home and the gentle, refined society of mother and sisters, is turned loose in a large school-room or playground, amongst a noisy, callous throng, of all sorts and sizes, of the *genus* school-boy. It is an ordeal from which the bravest may instinctively shrink—and suffer small reproach in consequence. In a long life many very momentous changes are sure to occur, but in dozens of cases this first will hold its own in the memory right to the very last. It will stand by itself, with its sharp outlines of loneliness, of isolation, of painful diffidence, unsoftened by any lapse of time. The most trivial circumstances and accessories of the starting introduction to a crowded class-room will often be stamped indelibly upon a lad's brain. The ink-stained desk in one corner, the battered books in another, will reappear years after, kindled into life by some like surroundings—just as the scent of a simple faded flower will sometimes bring back to the vision a whole landscape belonging to a long-past holiday trip.

Amongst future schoolfellows first acquaintances are to a great extent decisive. Boys are usually impulsive animals; they quickly rush to conclusions respecting the new-comer, and, having reached them, are not easily persuaded to retrace their steps. What they see—or imagine they see, which practically comes to much the same thing—at the outset colors their views right along the course. Not seldom a nickname is bestowed on the first day of a boy's school career, which clings to him to the final one. Any oddity of his personal appearance, dress, or manners will be seized upon with avidity, canvassed by the whole group, and emphasized until it becomes ludicrous, whether it was so before or not.

Even, sometimes—and one grieves to write it—deformities of physique, over which the new boy has certainly no control, and for which he has no responsibility, will be turned into weapons of bitter humiliation. Boys have scant pity as a class, however it may be individually. Being sturdy and whole of limb themselves, they lack that fellow-feeling with suffering and infirmity which is the foundation of genuine sympathy. It is not always so, of course; there are pleasant exceptions to be found even in schools dominated by the bad moral influence of a Mr. Creakle. But the exceptions, we fear, once again prove the rule.

The rattle of the coach-wheels has died away upon the gravel walk without, and, with the echo thereof fainter and fainter, has grown our new boy's courage. But his wits are soon fetched back from wool-gathering. The babble of voices that at first has been vague and indistinct in his ears resolves itself into a very tempest of questions, some *bona fide*, some satirical; some kindly, some threatening; some

easy to answer, some that he would do much to escape.

One lad wants to know his age, another how his "ma" was when he left her. One is curious respecting his wisdom teeth, another as to what supplies of pocket-money the neophyte can command. A fat, unctious-cheeked boy asks if he has any prime tarts in his box; a gloomy, austere one inquires, with an air of mystery, if he likes *stick liquorice.* Woe betide the tyro if, confused and baffled by this ordeal, and with his strange sense of desertion pressing in keen pain upon his heart, he should burst into tears. His prospects of future popularity will go under a cloud immediately, and many days will pass before the episode is forgotten. The designation of "milksop," thus earned accidentally, and very probably without reasonable desert, will stick. The handkerchief to a new boy's eyes acts on his comrades very much as the proverbial red rag on the nerves of a bull.

The best advice to the tried one upon this point is to maintain self-control at any cost—to take the questions calmly, and answer just as many as he may find convenient. Do not be over reticent unless there should be valid cause for reserve. To give confidence is the surest way to obtain it. And, on the other hand, guard carefully against "gush." In a group of lads there will often be one who can insinuate himself into very sacred recesses of a new boy's heart and draw from him confessions and little innocent stories that will afterwards be used against him as the spoils of a rude mirth. It is well to be on guard against the wiles of this provokingly sympathetic individual. He will then soon give the game up and show himself in his true colors.

Then comes to the new boy the important period of what are euphemistically spoken of as "larks." All sorts of games will be played upon him. His ignorance of school routine will be taken advantage of in a dozen different ways. Many schools have an unregistered but nevertheless rarely varying code of tricks for the tyro's delectation. Just as the merchantman's apprentice has to endure the details of a stereotyped ceremony on first crossing the Line, so the new scholar at "Our Academy" will be sent on a fool's errand here, and will endanger his shins by an unsuspected pitfall yonder. It will be best and safest to take it all in good part, and to refrain from anything approaching grumbling. If the unlucky one laughs persistently at disaster, and mildly edges his way out of blunders, the idea will quickly get afloat that there is good stuff in him, that he is a "real brick."

Never—except in the most unlikely, serious, and aggravated of all cases of practical joking—take the step of appealing to the authorities. To have fastened upon you at the very beginning the name of "tell-tale," "sneak," will be absolutely fatal, in nine instances out of ten, to any chance of school happiness. It is far better to bear in silence. Even should there be a downright bully in the school he will surely grow tired of his amusement, if he can raise no response of anger or supplication. Be patient, and all these petty annoyances will blow over. Games with new-comers are not confined to schools *pur et simple.* They are found wherever young life congregates.

I knew a young man some time ago who thought he had a mission to become a preacher of the Gospel, truly the highest and holiest of all callings. He was an artisan and uneducated, but friends worked him up, and by-and-by, with much effort, found an entrance for him into a training college. He went—after a great flourish of trumpets—but returned crestfallen in less than a fortnight. He used some singular excuses to account for his disappointing *fiasco*, but from hints dropped to acquaintances the opinion grew that practical jokes had been played upon him, as a new-comer, and in his loneliness these had driven him back to his bench—there very probably to vegetate for life.

I knew, too, a boy who tried the plan of telling the head master about tricks played upon him after lock-up, and who found no more peace until his father fetched him away, amidst the jeers (shown in every look and word and attitude) of those who, in happier circumstances, might have become his fast and life-long friends.

In school life, as in the wide arena beyond, it pays best to practice endurance, meekness, and good temper under trial. Let any new boy whom it concerns remember this in the hour of his temptation and his difficulties.

Lastly—for space has vanished—when in your turn you form one of a group to receive "a new boy," have in recollection the days of your own novitiate, and be gentle and considerate accordingly.

Spartan, the Newfoundland Dog.

BY RUTH LAMB.

AMONGST the many four-footed friends of whom I have delightful memories, my father's Newfoundland, "Spartan," stands out conspicuously. What a beauty he was! Large enough to serve as a steed for a little boy; gentle enough to bear any amount of pulling and hauling about by the youngsters. Black, with white breast, throat, and paws, and a tail like a great plume with a snowy tip. One

could not say he wagged that tail. He waved it.

It was a sight to see Spartan stretched full-length on the rug with two large cats lying across him, to say nothing of Leo, a waspish Italian greyhound, that wanted to drive away the cats and have Spartan's great body for his own sole resting-place.

Spartan could have throttled Leo and crunched up the cats with perfect ease, but instead of doing so he let them have their own way, only giving them a lazy glance sometimes, when the dog snarled and the cats swore a little more loudly than usual, as if he wondered they could be so stupid as to quarrel about trifles.

How that much-enduring beast was kissed, hugged, pulled about by his master's children! How droll it was to see him, when he missed his master, steal into the forbidden territory, the drawing-room, where hung a good portrait of him, and seem to find comfort in gazing at the copy in the absence of the original.

Spartan and his master spent several happy years together, and travelled thousands of miles in company.

Once they suffered shipwreck on the return voyage, and after an absence of several months from home. The vessel during a dense fog got aground on the "Knock Sands"—near neighbors to the famous "Goodwins."

The seamen got out the boats, but my father resolved to stay by his ship so long as there was the smallest hope, and at first refused to leave it. The men begged him to go, and at last two of them tried to force him into the boat.

Spartan was the pet and playfellow of every man on board, but he could not permit the best amongst them to meddle with his master. When the first sailor laid hold of the captain, the grand dog flew at him, and, in less time than it takes to tell, laid him flat on his back and held him until my father bade him leave go.

Then the great fellow laid down at his master's feet with a menacing air that seemed to say, "Try that again, if you dare."

The men lingered with the boats, and as the case soon became hopeless, my father at length left the doomed vessel. But he was not quite the last to quit the ship, for Spartan saw him safe in the boat, and then leaped in after him.

When telling us the story of that shipwreck and of Spartan's doings, my father's eyes used to light up with pleasure as he spoke of the grand, old Newfoundland. And we children, never satisfied without hearing just a little more than the story, wanted to know what my father saved beside his life and Spartan when his good ship went down. A smile played on his kind face as he answered, "Well, only three things—my old violin, a MS. written by my uncle, whose namesake I was, and this."

"This" was his pocket Bible. I have it to-day—every leaf yellow, and most of them stained with salt water, his firm, handsome writing on the fly-leaf. But I think there have been some salt drops on the pages that did not come from the sea. And in going over the list of articles saved from the wreck—when money, instruments, all that most men would have thought precious, were lost—one reads the character of the man. Here I will stop. I began to tell about the dog, but somehow I fancy those who read Spartan's brief memoir will leave off, thinking most of Spartan's master.

House Plants.

POTTED plants should not be wet too often. They should not be watered until they really need it. It will be evident that they require wetting, if in taking the earth from the pot it crumbles to pieces like dust; a sure sign is to knock on the side of the pot, near the middle, with the finger knuckle. If it gives forth a hollow ring, the plant needs water; if there is a dull sound, there is still moisture enough to sustain the plant. Plants must not be wet more than once or twice a day; on dry, clear days they require more water than on damp, cloudy days. On the other hand the earth must not be allowed to dry out entirely, for that is also very injurious. In wetting them the water must be poured on in such a way that it will run out again through the hole in the bottom of the pot. If the earth gets too dry, it is best to place the pot in water, so that the water will saturate the dirt very gradually. They may be watered at any hour of the day, except when the sun is shining on the pot or has just left it; for the earth gets hot when the sun shines on it, and then if cold water is poured on it, it will cool off too rapidly. Keep them free from dust, if possible. Cover them over at sweeping time. If the plants are on a table, contrive an upright post or stick to be set in a hole in the middle of the table to hold up the centre of a spread of some kind that will cover the plants. In the absence of such protection, contrive some method of using old newspapers. Before sweeping protect the plants by the use of a covering, and let this remain over them until the dust has completely settled. All smooth-leaved plants, especially ivy, cape jessamine, camellias, and the like, should have their leaves washed with a soft sponge—a rag will answer—on both sides, with tepid

water, at least once a week. If this is once tried it will be found much less trouble than one would suppose, and the increased beauty of the foliage will lead to its repetition. Rough-leaved plants, such as geraniums and many others, cannot be washed to advantage. Set these in a bath-tub, or in a sink, and give their leaves a good drenching by using a garden syringe, if one is at hand, or else a watering-pot, one with fine holes, holding it up high, so that the water will fall with force upon the leaves.

Our Girl's Department.

This department is intended exclusively for "Our Girls," and we hope to make it both interesting and instructive, and to this end we ask our young lady readers to assist by contributions, suggestions, or illustrations. There are thousands of little things that can be, and have been, made and done by young ladies, pertaining to decorative art, needlework, etc., etc., that would be gladly followed but for a want of knowledge on the subject, and we know of no more pleasing task for a lady than that of teaching her younger sisters that which they are anxious to learn, and which may prove of real benefit to them in the future, as well as being useful and interesting for the present. We trust we will have no difficulty in persuading those who have something nice to show or speak of, to make use of this department. Remember, it is open to all, and if you have anything worth knowing suitable for this column, send it along, and we will give it our best attention. Do not be afraid to write because you may fancy your composition is not perfect, or have other scruples of a similar kind. Do the best you can, and leave the rest to the editor of this department, and we are sure you will be pleased with your work.

ONE of the saddest things about human nature is that one may guide others in the path of life without walking in it herself—that she may be a pilot and yet a castaway.

—Welcome hither, as is spring to earth. *Shakespere.*

—A generous friendship no cold medium knows; burns with one love, with one resentment glows.—*Pope.*

—It's no in books, it's no in lear,
To make us truly blest—
If happiness has not her seat
And centre in the breast.
We may be wise, or rich, or great,
But never can be blest.
Burns.

—A new style of vase has a surface imitating pearls, over which is a design of water lilies.

—Gold-fish globes in Austrian crackle glass show fresh designs in violets, fern sprays, and delicate flowers generally.

—A mossy surface, which is given to chinaware, aids the pleasing effect of flowers in relief straying over the pieces.

—A pretty toilet-piece is a rose-tinged shell, opening and disclosing a bottle, also in the pottery, entwined with wild roses.

—A unique lamp-shade may be made of a straight piece of bright-colored silk or satin. Shirr the top to fit the globe, and finish the bottom with lace.

—Corner closets and corner "cupboards" are revived, and utilize space, especially where it is limited. They ought to be more common, and not so difficult of achievement.

—Flower decorations are taking on conventional forms, much brilliant color, very little foliage, and a formality that is quite in keeping with the solemnity of a dinner-party.

—Hall lamps are now square in shape and made of beautifully-designed colored glass, each panel being different. Usually they are mounted in brass and suspended by a short chain or pole of twisted brass.

—Pretty lambrequins may be made of the Aida linen canvas worked in long stitches of olive, pink, gold and blue. On either side of this is black velvet ribbon, feather stitched on with gold silk.

—A handsome table cover is made of the basket flannel now so much in vogue. Take a square of it in crimson or olive and work a pretty border in bright silks. Finish with a fringe of crewel wool tied in around the edge.

—For a banner screen a new idea is a design on discs. These are cut out in satin and appliqued on to deep-toned plush or velvet, while designs of flowers or fruit are worked upon them in filoselles or crewels.

— A tidy that will prove both handsome and durable is made of three stripes of zephyr Java canvas, two cardinal and one of drab. Each stripe is worked with a pretty vine and the ends cut in points. The red pieces are crocheted around with drab and the drab with red. Sew the stripes together, having the drab in the middle, and tip each point with a tassel of wool of the color of the stripe.

— For mantle valances the pleasantest work is done on the coarse linen canvas called "Aida canvas," and wrought in double cross-stitches with single zephyr wool. This work grows rapidly, and is simple and easily done. The fringe is knotted when bought, and the worker ties in wools of different colors in each strand of the fringe; a border of drawn work is placed above the fringe.

— Eastern inlaid applique, used for covers, carpets, and housings, is chiefly made at Resht. It may be briefly summed up as patchwork made with embroidery. The colors used are among the most brilliant, and the patches, which are of cloth, are cut so small, and into such intricate patterns that it is marvelous how they can be joined together. Flowers, birds, and animals are freely used, besides geometric and other patterns. The pieces are stitched together, and every seam afterward concealed with lines of chain-stitch worked over them with colored silks. Not content with a single line of chain-stitch, two or three lines upon each petal of a flower or feather of a bird are embroidered, and each line is worked in a different colored silk, while in many places the entire patch is concealed with embroidery either of gold thread or silk, worked so as to make a shaded design. Frequently, instead of chain-stitches, lines are made with fine gold threads, not laid on flat, but twisted into very small circles, laid so as to form a broad compact line. Gold and silver foil is used instead of gold or silk; it is cut very narrow and folded so as to form zigzag lines, which are then sewed to the foundation, either as lines or to fill certain spaces.

FLORICULTURE FOR JUNE.

"And now the earth prolific swells
With leafy buds and flowery bells;
And all along the branches creeping,
And through the velvet foliage peeping,
Little infant fruits we see
Nursing into maturity."

From the Greek.

The flower harvest has begun. We have come with a stride into summer. But Nature has been at work while our short spring lasted, and the garden bears witness to her bountiful preparations for summer's reception. We must get up early now to keep pace with the daily growth of even our little piece of the world.

Now is the time to make a bargain with summer, to this effect: "If I will give an hour or so before breakfast to making my garden a credit to you, will you give me a little insight into your ways of doing things, and in the end a pretty garden to show for my pains?" I think summer will come to terms with you; she is by nature generous. Your part of the bargain means that you put on a shade hat and garden gloves (though *I* never could work in gloves), and weed, water, and rake every morning, making the toilet of your garden as conscientiously as you do your own.

Your early-planted seeds, etc., should be growing well and beginning to blossom. If you are not tired of planting, you can provide flowers for the dreary days of late autumn by planting seeds of aster and zinnia now, and some strong gladiolus bulbs. You certainly should have a few of the last, and also a plant or more of scarlet salvia; nothing makes a more brilliant display or is more certain to do well.

Don't be chary of picking your early blossoms. The saying "There is that scattereth and yet increaseth" is beautifully exemplified in the flower-garden; you will have more flowers and finer if you keep them well picked off at first. Verbenas and pansies are notable instances of this. Leave a pansy bed alone for awhile, and it will be covered with long-stemmed seedpods, and what flowers there are will be small and poor, and

quite unlike the earlier blooms. Geraniums, too, look very untidy when the flower stalks are left on them, and mignonette soon runs up long seedheads unless it is picked and kept making new growth too fast to think of seeding.

Water your garden thoroughly early in the morning and after sundown. Look out for insects in the early morning when you go your rounds. Soapsuds on rose-bushes and verbenas will help keep off insects; the florist uses whale-oil soap. You will have to use a syringe to get at the under side of the leaves. To destroy the little black flea which eats up sweet alyssum, sweet pea, etc., soon after they come up, dust the plants over with soot.

See how one thing leads to another. Do you not begin to feel by this time how much use you could make of a microscope, a work on entomology, or one on botany?

I have thought that there might be people in the city who got "left behind" this spring with their window gardening through being occupied with the horrors of "moving," or because the changeable spring weather misled them, and summer was upon them before they knew it. They have thus lost the pleasure of raising their plants from seed, but can still, with the florists' aid, make their windows gay, and keep them so by their own skill and care. If you mean to have a window-box, get lobelia, nierembergia, tropoelum (major and minor), mignonette, coleus, heliotrope, verbenas, and (if there is any room left) geraniums and sweet alyssum. These all like a hot sun. If you can raise a trellis, or have some sort of arched handle arrangement on your box, plant maurandia to grow over it; nothing is prettier or grows more rapidly. Maderia vine or German ivy will grow well in a sunny exposure, and the lysimachia or common moneywort makes a pretty fringe for a box.

Have a fine-nosed watering-pot for your window garden, and keep your plants as free from dust as possible. Water twice a day in sunny weather, and let your morning watering be done *early*, before the sun is hot.

As for old plants of geranium, fuchsia, or roses that bloomed for you last winter, if you cut them back a month or so ago, and withheld water from them for awhile, they may begin to grow again now. Wash and scald their pots thoroughly, scrubbing off all the green mold. It is sometimes a good plan to crumble off a little of the old soil and mix in fresh, instead of potting in larger pots. Do not expect blossoms off them, but pick off any flowers that appear; then if the plants make a good strong growth, in July or August you will be able to make cuttings from them which will give you fine plants for next winter.

Have you ever tried to make a living screen? Fix castors on a box the length of the window you wish to screen, and at the ends place uprights of the height you desire; then place a bar or stretch a wire across the top, and at the bottom a few inches above the box, connecting the uprights; from one to the other of these stretch strings or wires; then plant German ivy, Madeira vine, smilax, or maurandia on each side of them, and train up the strings.

This screen can be turned occasionally to give both sides the benefit of the sunshine.

A screen of maurandia, showing a mass of green and pink or green and purple, according to the variety you have planted, and with its outreaching sprays forming a thousand graceful curves round the edge of the frame, and throwing the loveliest shadows, is a pleasant object in a city house. Small screens, that you may roll between you and the sun which shines in your eyes while writing or reading, may be made the same way, by fixing flower frames of suitable shape and size in small boxes on castors. The vines having once grown will preserve their beauty for a long time.

Who knows what brilliant fancies you may not have the honor of originating! This is but one of a thousand "dainty devices" which an acquaintance with the flowers will prompt you to.

As Edward Youl says twice over in his lovely spring poem, "Friendship with the flowers some noble thoughts begets!"

Ellen M. Hooper.

Removal.

WE take this opportunity of informing our friends that we have removed our editorial and business offices to 294 Broadway, New York, where we have secured a suite of spacious and pleasant rooms.

It will give us pleasure to have any of our friends call and see us whenever they can make it convenient to do so.

Our printing-office is situated at No. 15 Dey street, and is therefore some distance from our editorial *sanctum*, which is a much better arrangement than the former one, when the printing, editorial and business offices were in one building.

The increase of our business within the last few years has rendered a removal to more spacious quarters imperative; and in responding to this requirement we have been fortunate in securing the rooms we now occupy for a term of years, a condition that will warrant us in expending a reasonable sum in fitting-up our offices in a suitable manner, an undertaking that would be unwise under a short lease.

A writer on mechanical subjects advises young mechanics to cultivate the nerves and muscles of each hand, so that they can use a hammer, chisel, wrench, file, or any other tool, as well with one hand as with the other; so that they can turn a handle or hand wheel one way with one hand, and another one the other way with the other hand, both at the same time; or so that they can turn them both one way or different ways at different speeds. Such practice in turning handles will be found indispensable in learning to become an expert on the lathe, planer or other machine tool. All that is required to learn this is a little practice until the motion of one limb or member is not at all governed or controlled by the motion of another. There are many things that may be done with one hand as well as the other, but there are some instances when the time required to educate one hand to expertness is as much as the owner can afford. Indeed, for some of the finer manual operations it requires half a lifetime to educate the hand to perform its duties satisfactorily; and to accustom both hands to perform the same performances alike must, as a matter of course, take a great deal more time than if one hand was prepared to do the same duty. Ambidexterity for ordinary operations is to be desired, but for the finer order of artistic and mechanical manipulation, though desirable, is not to be sought after, as the pursuit would be simply a waste of precious time.

The telephone as yet is only in its infancy, yet what wonders have already been performed with it! A few weeks ago a number of very successful experiments were performed in the Postal Telegraph Company's office, New York. The telephoning was between New York and Chicago, and the instrument used was the double Edison telephone, which was employed four years ago in establishing communication between Toledo and Milwaukee by way of Detroit and Chicago, a distance of over 500 miles. It consists of two Edison telephones attached to a single mouthpiece in such a manner that

one can talk into both at the same time, and get their combined effect upon the line connecting the two. It seems to matter little, however, what instrument is used, for the various experiments that have been made with different points at a great distance have all been attended with similar results. It is thought, therefore, that the great success attained must be attributed to the compound copper wires of the Postal Telegraph Company, through which the sounds are transmitted. They consist of a core of steel surrounded by a coating of copper, so combining the strength of the ordinary wires with the conductivity of the copper covering. With these wires there appears to be no limit to the possible use to which telephones can be put. Every word that was said in the Chicago office could be heard as distinctly as when using the wires that run from office to office in this city, and the operators in Chicago were able readily to distinguish the voices of the gentlemen in the New York office. We see no reason why some of our boy readers cannot construct telephones in their own houses, or from there to the houses of some of their near friends. Telephones are easy to make and both useful and amusing, as a great deal of innocent fun can be taken out of them when known friends are at each end. In future issues of the YOUNG SCIENTIST we intend giving this subject our attention, and hope to give such instructions and illustrations as will enable many of our readers to construct telephones of their own.

We believe it was John B. Gough who said that "if you want to succeed in the world, you must make your own opportunities as you go on." Young people who are always waiting, Micawberlike, for "something to turn up," wait long and wearily. It is folly of the most idiotic kind to sit by the wayside and wait for some one to invite you to ride in his carriage to prosperity and fame. We are sure none of our readers—boys or girls—are of the dillydally sort, that are afraid to take hold of work in all its phases, and persistently stick to it until a satisfactory end is attained; but it may be that some of our young friends may not be the worse for reminding that thoroughness, expertness and competency are only obtained by persevering and persistent workers, and that, without these qualities, no opportunities for honest advancement are possible. It is only the competent and industrious that can make opportunities and take advantage of them. There is no rest for the prosperous, and there is none required, for to be busy is to be happy, and to be happy is to be good and useful.

Our Book Table.

The Engineer's Slide-Rule and its Applications. Being a complete investigation of the principles upon which the slide-rule is constructed, together with the method of its application to all the purposes of the practical mechanic. By William Tonkes. Industrial Publication Company, New York. Paper. Price 25 cents.

This excellent little treatise on the engineer's slide-rule is an advanced companion of work manual No. 2, "The Mechanic's Slide-Rule, and How to Use it." Both are particularly good works for mechanics, the one under notice being especially adapted to the wants and requirements of students in mechanical and civil engineering. Young men who are preparing themselves for following any of the constructive pursuits would find it very much to their advantage to become acquainted with the workings of the slide-rule. The study is not a difficult one, and when once mastered, is capable of being applied with exceeding rapidity to the solution of some of the most tedious and irksome problems. Indeed, the slide-rule, in the hands of an expert, is a kind of an elastic calculating machine, and is made to perform some of the most difficult and perplexing feats in mathematics with a minimum of labor. The book under review explains how these things are accomplished, and tells the reasons why the solutions may be performed by the rule clearly and in the simplest of language.

The American Boy's Handy Book. What to do and How to do it. By D. C. Beard. Chas. Scribner's Sons, New York, 1882.

This is really what its title claims it to be: "The American Boy's Handy Book." The object of the work is to teach boys not only how to use their toys and playthings, but also how to make and care for them, and this, we think, the author strives to do in an easy and pleasing manner. The chapters on kites are clear and interesting, and the instructions given for making these aerial playthings are simple and to the point. So also are the instructions for amateur boat-build-

ing, fishing, camping-out, private theatricals, and the other matters the book discusses. Indeed, we know of but few other books we would prefer placing in the hands of our boys sooner than the one under notice, for from the preface to index there is not a line that does not contain some useful hint or idea that, if followed out, would surely lead to moral health and active usefulness. If more books of this kind were found on the tables in our households than there are, and less of the "goody-goody" trash on the one hand and of the "scalp-taking, blood-and-thundery" kind on the other, we should have fewer boy criminals and more solid, sensible, and useful men. We are fully in accord with the author, who, in his preface, says, "Let the boys make their own kites and bows and arrows; they will find a double pleasure in them, and value them accordingly, to say nothing of the education involved in the successful construction of their homemade playthings. The development of a love of harmless fun is itself no valueless consideration. The baneful and destroying pleasures that offer themselves with an almost irresistible fascination to idle and unoccupied minds find no place with healthy activity and hearty interests in boyhood sports."

The Metal-Worker Pattern Book. A practical treatise on the art and science of pattern-cutting as applied to sheet metal work. By A. O. Kittredge. David Williams, publisher, 83 Reade street, N.w York.

The modern tendency to apply sheet metal to many purposes heretofore never dreamed of, has rendered it imperative that workers in this material should possess an accurate knowledge as to the manner of cutting out patterns and shapes for the multifarious forms they may be called upon to execute.

A number of books have been written with a view of enlightening the workman on this subject, and aiding him to obtain good result with as little expenditure of labor and material as possible, and no doubt these books did good service in their time; but the art of sheet metal working, like all other mechanical arts, kept advancing, and new methods and new ideas have developed with each step advanced, until the old methods and manners of manipulation are become obsolete and valueless. The work before us has been prepared to meet present wants and present practices, and is thorough, reliable, comprehensive, and is, withal, written in a plain and simple style, and in language that any mechanic should understand. The work is divided into five general chapters. In the first, definitions and technicalities are considered. The second discusses drawing tools and materials, while the third takes up geometrical problems and their relations to pattern-cutting. The fourth describes the art and science of pattern-cutting, and the fifth and last consists chiefly of illustrated methods of solving the various problems of every-day practice. The work is profusely illustrated, well printed, and handsomely and substantially bound in cloth. The book is one that can be recommended, and will prove invaluable to mechanics who work in sheet metal.

Astronomy for Amateurs.—June.

BY BERLIN H. WRIGHT.

THE PLANETS.—JUNE, 1883.

(All Computations are for the Latitude and Meridian of New York City.)

Venus, in her eastward march past the stars, passes between the Pleiades and Hyades about the middle of the month, and is one and one-half degrees south of the Moon on the 2d. She will pass very close to the planet Saturn on the 19th, being, when nearest, only about one-half of a degree north of him. They can both be brought in the same field of a telescope, and thus make interesting objects. Venus' shape will be somewhat oval, as about nine-tenths of the diameter of her illuminated hemisphere will be visible. She rises as follows:

10th—3h. 6m. morn.
20th—3h. 4m. "
30th—3h. 7m. "

Saturn is about five degrees north of *Alpha Tauri* (*Aldebaran*), and with Venus, the Pleiades and Hyades makes a very conspicuous cluster of bright and interesting objects. The Moon will be in their midst on the morning of the 4th, almost occulting Saturn, passing just below him. He rises on the 10th at 3.40 morn.; 20th, 2.29 morn.

Mars is west of the Pleiades, rising as follows:

10th—2h. 24m. morn.
20th 2h. 4m. "
30th—1h. 46m. "

The Moon will be in conjunction with him on the 2d and 30th, passing very close and south of him in both instances. He will be 1° 7′ north of Neptune on the 27th.

Jupiter, being in conjunction with the Sun on the 5th of next month, will be too near the Sun to be well seen this month.

OCCULTATION.

The first magnitude star, *Alpha Virginis* (*Spica*), will be occulted by the Moon on the 15th. The immersion will occur at 1h. 13m. in the morning, Washington mean time.

METEORS.

The meteors of June are as follows: First, The Aquilids, which radiate from a point near *Alpha Aquila* (*Altair*), about midway between that star and Job's Coffin, east of it. They are slow-moving, and extend over a long period, beginning on the 7th. Second, a group radiating from *Alpha Cepheus*, beginning about the 11th and running through the month. Third, The Draconids II., radiating from the first coil of Draco,

beginning on the 28th. Fourth, The Pegasids II., radiating from a point about midway between the second magnitude star, *Alpha Pegasus* (in the southwest corner of the Square of Pegasus), and the λ of Aquarius. The earth enters this group on the 28th also. Fifth, The Coronids, radiating from a point five degrees south of the beautiful little cluster known as the Northern Crown. The earth passes out of this group on the 30th.

EPHEMERIDES OF THE PRINCIPAL STARS AND CLUSTERS, JUNE 22, 1883.

	H.	*M.*
Alpha Andromeda (Alpheratz) rises	10	8 eve.
Omicron Ceti (Mira) variable, "	3	26 mor.
Beta Persei (Algol) " "	11	48 eve.
Eta Tauri (Alcyone or Light of Pleiades) rises	2	12 mor.
Alpha Tauri (Aldebaran) rises	3	31 "
Alpha Aurigæ (Capella) "	0	50 "
Beta Orionis (Rigel) invisible.		
Alpha Orionis (Betelguese) invisible.		
Alpha Canis Majoris (Sirius or Dog Star) invisible.		
Alpha Canis Minoris (Procyon) sets	7	50 eve.
Alpha Leonis (Regulus) sets	10	43 "
Alpha Virginis (Spica) sets	0	43 mor.
Alpha Bootis (Arcturus) in merid.	8	8 eve.
Alpha Scorpionis (Antares) in meridian	10	19 "
Alpha Lyrae (Vega) in meridian	0	34 mor.
Alpha Aquillae (Altair) rises	7	13 eve.
Alpha Cygni (Deneb) in meridian	2	38 mor.
Alpha Pisces Australis (Fomalhaut) rises	0	52 "

Penn Yan, Yates Co., N. Y.

Novelties for Amateurs.

A very ingenious device for attaching small hooks to walls has recently been brought out by W. H. Hasbrouck, No. 91 Liberty street, New York.

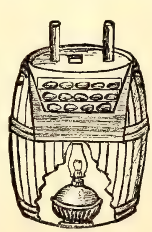
The device consists of a piece of strong paper, printed and cut to some appropriate design, as shown in the cuts. The paper is covered with some strongly adhesive gum on the back, and a small wire hook, having two prongs, is fastened to the paper by the prongs passing through the paper and being bent over or "clinched" on the back side,

The second cut shows a few of the designs

made, but there are styles such as ivy and autumn leaves, and other elegant designs lithographed in brilliant colors.

The adhesive hooks can be used in many places where tacks or nails cannot be driven at all; as on stone or brick walls, metal surfaces, glass, etc., and are easily put up, as they only require to be moistened on the back and pressed firmly against the wall or other surface for a few moments, when they are ready for use. For light articles, such as small pictures, plaques, calendars, match-boxes, almanacs, time-tables, show-cards, brushes, toilet-cases, catch-alls, watches, etc., they are a decided improvement over nails or tacks, and in no case whatever do they disfigure a wall.

For hundreds of years it has been the custom of the Egyptians to hatch chickens by artificial means; the first country in Europe to adopt this method on a large scale was France. About ten years ago it was introduced into America, and now thousands of chickens are hatched in incubators in the vicinity of New York every year. This system has several advantages over the old way. The time occupied by a hen in setting and rearing a brood of chicks is about three months; this occurs at the season of the year which is most favorable for laying. During this time she would probably produce sixty or seventy eggs—another advantage being to secure early birds for the market, when broilers are worth from fifty cents to one dollar per pound. There is no occupation more pleasant or profitable to boys on farms or in villages than rearing chickens. It requires very little capital, and the returns in cash from sale of eggs and chickens will make an easily-earned income.



There are several manufacturers of incubators and artificial mothers; all are expensive, ranging in price from $25

to $600, while the principle of constructing one is so simple, that any boy with ordinary genius can construct one himself at a trifling expense.

The above cut represents one of the cheap homemade kind. It contains every principle in which the more expensive ones are made, excepting in two particulars—it is not self-regulating, and it has not the arrangement by which all the eggs can be turned at once. It requires very little care and attention and does its work well.

Paul Gustave Dore.

Gustave Dore, the famous painter and designer, died in Paris, Jan. 23rd. Paul Gustave Dore was born in Strasburg in January, 1832, and received his early instruction in the lyceums of that city and of Bourg. Before he was twelve years old he had developed a wonderful facility with the pencil, and at a very early age he contributed comic sketches to the *Journal Pour Rire* and other popular newspapers. His education was completed in Paris, and while still a schoolboy his work was recognized as giving more than ordinary promise. His first great work, however, was produced during the period of the Crimean war, and was illustrative of battle-scenes. He exhibited "Les Pins Sau vages," "Le Lendemain de l'Orage," "Les Deux Meres," and "La Bataille d'Alma," in 1855; and "La Bataille d'Inkermann," in 1857.

Dore was, in fact, a precocious wonder. He could draw when a child, and when success came to him, it came with a rush. Before he was twenty-five he had illustrated "Rabelais" and the "Contes Drolatiques" of Balzac, and had given rein to his wild and and fantastical humor in a series of grotesque yet powerful drawings illustrative of the legend of the "Wandering Jew." In rapid succession followed his illustrations of "Montaigne" (1857), Taine's "Voyage aux Pyrennes" (1859), Dante's "Divinia Commedia" (1861), Chateaubriand's "Atala" (1862), "Don Quixote" (1863), "Paradise Lost" (1865), the "Holy Bible" (1866), Tennyson's "Idyls of the King" (1866–'67), and La Fontaine's "Fables" (1867). It is by his illustrations that Dore's highest excellence as an artist will be recognized, and his "Don Quixote" and "Dante" were magnificent efforts.

Dore was a most versatile genius, and al though not as successful in color as in black and white, some of his figure pieces were of considerable merit. In addition to those already named, his most noticeable works in oil were the "Paolo and Francesca di Rimina;" the "Gambling-Hall at Baden-Baden;" the "Neophyte" (1868); the "Triumph of Christianity;" and his most ambitious group, the "Christ Leaving the Prætorium," an immense picture, covering a canvas thirty by twenty feet, which was exhibited in London and elsewhere. Dore was a tireless and indefatigable worker, and is said to have executed not less than 50,000 designs. He had a gallery of his own paintings in Paris, another in New York, and another in London, where his "Christ's Entry into Jerusalem," "The Flight into Egypt," "Spanish Peasants," "Mont Blanc" and other works were shown. At the Paris Exposition in 1878 he exhibited a colossal vase, ornamented with 150 figures. One of his latest works was a sculptural group, "The Prize of Glory," a young hero dying beneath the kiss of glory. He was decorated with the Cross of the Legion of Honor, Aug. 15th, 1861. At the time of his death he was engaged on a series of illustrations of Shakespeare, and among his latest labors must be included his Poe's "Raven," now in press. He was a sculptor as well as a painter, and had just finished his monument to the elder Dumas, which is considered as one of the finest works of art produced in this century. M. Dore was never married.

Scientific News.

—Many persons are puzzled to understand what the terms fourpenny, sixpenny, tenpenny, mean as applied to nails. Fourpenny means four pounds to the thousand nails, sixpenny six pounds to the thousand nails, and so on. It is an old English term, meaning at first tenpound nails (the thousand being understood); but the old Englishman clipped it to tenpenny, and from that it degenerated until penny was substituted for pounds. So when you ask for fourpenny nowadays you want those which will weigh four pounds. When a thousand nails weigh less than a pound they are called tacks, etc., and are reckoned by ounces.

—An English work gives the origin of the "Oak and Ash Tradition" as follows: If the oak gets into leaf before the ash, we may expect a fine and productive year; if the ash precedes the oak, we may anticipate a cold summer and unproductive autumn. In the years 1816, '17, '21, '23 '28, '29, '30. '38, '40, '45, '50 and '59 the ash was in leaf a full month before the oak, and the autumns were unfavorable. In 1831, '33, '39, '53 and '60, the two species of trees came into leaf about the same time, and the years were not remarkable either for plenty or the reverse. But in 1818, '19, '20, '22, '24, '25, '26, '27, '33, '34, '35, '36, '38, '42, '46, '54, '58 and '69, the oak shows its foliage several weeks before the ash, and the summers of those years were dry and warm and the harvests abundant.

— Joseph Albert, photographer to the court at Vienna, has finally succeeded in inventing photography to render the natural colors in the picture by a photographic steam press of his own construction, without the aid of a pencil. An expert painter could hardly give the colors of the object more faithfully in living reality and with the distinctness to the nicest shades than in these colored photographs by the Albert press. The secret of the invention consists in the analysis of the white light into three colors, yellow, blue, and red, and in the recovery of the three colors ready for the press. On a plate, chemically prepared so as to receive but the yellow parts of the light, and the tones of the colors of the object to be reflected, the first photograph is taken, when a negative of that plate is at once put under the press, whose cylinder is dubbed over with yellow paint. None but the tones of the yellow colors are now seen in the impression. After that the object is photographed on the plate made to reflect but the blue colors. This plate now under the press reflects a blue impression, the cylinder being dubbed over with blue paint. In the same manner it receives but the tones of the red colors by means of a third plate. Printing the individual pictures of the yellow, blue and red over each other, a picture is produced true to nature, the colors intermixing by having been printed over each other. The idea, long entertained and prosecuted by Albert, to photograph colors, may no longer be considered as not feasible. It is very hard at the present time to foretell how great a revolution this new invention will produce in the many departments of art.

Practical Hints.

Cement for Fastening Wood to Stone.—Melt together 4 parts of pitch and 1 of wax, and add 4 parts of pounded brick-dust or chalk. It must be warmed before using, and applied thinly to the surfaces to be joined.

To Produce Imitation Ebony.—Take half a gallon of strong vinegar, one pound of extract of logwood, a quarter of a pound of copperas, two ounces of China blue, and one ounce of nutgall. Put these into an iron pot and boil them over a slow fire till they are well dissolved; when cool the mixture is ready for use; add a gill of iron filings steeped in vinegar. The above makes a perfect jet black, equal to the best black ebony. A very good black is obtained by a solution of sulphate of copper and nitric acid; when dry, the work should have a coat of strong logwood stain. —*Bitmead's Practical French Polisher.*

To Imitate Ground Glass.—Put a piece of putty in muslin, twist the fabric tight, and tie it into the shape of a pad. Well clean the glass first, and then apply the putty by dabbing it equally all over the glass. The putty will exude sufficiently through the muslin to render the glass opaque. Let it dry hard and then varnish. If a pattern is required, cut it out on paper as a stencil plate, and fix it on the glass before applying the putty; then proceed as above, and remove the stencil when the dabbing is completed. If there should be any objection to the appearance of clear spaces, cover them with slightly opaque varnish.

Notes and Queries.

In continuing this department, which has been found of so much value, we would remind our readers who wish for information on any of the arts and sciences, that they are cordially invited to make their wants known through this column, and those of them who can furnish accurate answers to questions asked are requested to send in replies. Doubtless many of our subscribers may know of methods, processes, or devices that may be better or more suitable for the particular case in question than anything generally known, and it is this reason that induces us to keep this department open for a medium, where an interchange of ideas and practices may be made to the advantage of all our readers. Correspondents will please send their full address when forwarding their communications—either questions or answers—not for publication, unless expressly so stated, but so that we may know where to find the writer if desirable. Communications should be sent in on or before the first of each month previous to publication, to insure insertion in next issue.

Answers.

71. Oil Colors.—A set of materials and oil colors for flower painting could be made up for from five to eight dollars. You could paint on paper or on wooden panels. If you desire the former get a sketch block for oil painting, which contains 32 sheets, seven by ten inches, for a dollar; ten by fourteen inches for two dollars. If you prefer wood you can get polished panels from forty cents up to $1.60 apiece. You can order at Devoe's, corner of Fulton and William streets, New York, sketch of daisies for plaque. You can also order at same place all your materials mentioned; also "Tilton's Outline Studies of Familiar Wild Flowers," in two parts, $1.50 each part; and "Tilton's Familiar Garden Flowers," in two parts, each part illustrated by twenty chromo-lithographic plates.—Nettie, N. Y.

72. Steamboats.—A kind of a steamboat was patented in England in 1737 by a man named Hull. His patent, and a pamphlet written by him setting forth the great advantages of his invention, are still in existence. Jouffroy tried Hulls' idea on the Saone at Lyons in 1782. Miller, of Dalswinton, and Symington, tried their steamboat on the Clyde in 1789, and accomplished seven miles in the hour. The Charlotte Dundas steam-tug was placed on the Forth and Clyde Canal in 1801. A barge was propelled by steam on the Thames, at two miles an hour against tide, on July 1, 1801. Fulton's steamboat was tried, and collapsed, on the Seine, August 9, 1803. Having visited Symington, and taken notes of the Charlotte Dundas, Fulton tried again, and successfully, on the Hudson at New York, with one of Boulton and Watt's engines sent out to him from England in 1806, since which time steamboats have always been on the Hudson. The improvements made in steam engines by Boulton and Watt rendered successful steamboating possible. The Comet, the first passenger steamboat in Great Britain, started on the Clyde in 1811; the Norwich and Yarmouth boats began in 1813, the London and Gravesend boats in 1815. The first steam-packet to cross the Atlantic was the Savannah, which reached Liverpool in twenty-six days from New York on July 15, 1819. The first English steamer from London to New York was

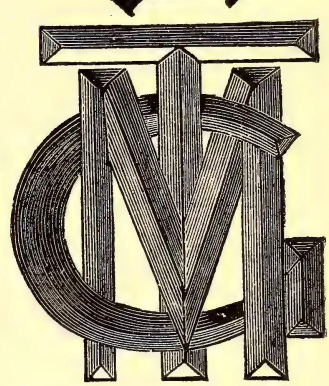
the Sirius, in 1838. The Sirius on this occasion took out Dr. Lardner, who had spent a vast deal of time in "proving the voyage impossible!!"—ONE JENKINS.

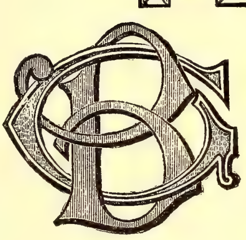
73. THE END OF THE WORLD.—The end of the world is your own death, as far as you are concerned, and it is wise to be always ready for that. No man can fix a date for such an event. The year 1000 was to see the end, but it did not. De Cusa pledged himself to 1704, Swedenborg to 1757, Bengel to 1836, Miller to 1843, Cumming to 1866, Mrs. Shipton to 1881, and there have been many others, and the world lives on and laughs at them. We are not aware that there are any impending predictions at this time. There was a report a few years ago to the effect that Proctor, the astronomer, had predicted that the earth and some comet would collide, resulting in a complete smashing-up of the former. Proctor, however, denied the report. We are inclined to believe that for the future it will be best for timid people to remain satisfied on this point and await events, for it is not likely that any sane person will again predict the exact time when the general break-up of the earth will take place.—CLERICUS.

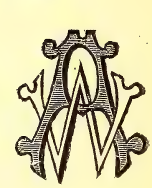
74. PAINTING PHOTOGRAPHS.—Thirza McB. should procure the following for painting photographs in ordinary water colors. Gouache or Chinese white is generally used. The colors necessary for this will be Chinese white, yellow ochre, rose madder, cobalt, sepia, light red, vermilion, black, gamboge (or cadmium). The surface of the photograph is prepared by washing it over with a size which comes for that purpose, and can be procured of any dealer in art materials. The whole of these materials, or any of a like kind, may be obtained in this city—New York—at Devoe's, Fulton street.—AMATEUR.

75. GLASS.—The Hebrew word *zechuchith* is employed to denote "glass." Whether it has this signification in Job xxvii., 17, or whether it relates to some precious stone, is a debatable question. The word *zechuchith* means a pure substance, which does not imply transparency. The Phœnicians, though credited with the invention of glass, have not left any other records except the names of some makers of glass vessels. On some Phœnician relics occurs the name of Artas the Zidonian. Whether the Jews, as neighbors of the Phœnicians, were manufacturers of glass during the Biblical period of their history cannot be proved by any relics. Of glass which came from Assyrian excavations, the British Museum has several specimens; one of 700 B.C. bears the inscription of Sargon. A more direct insight is given by the Egyptian monuments, where we have pictorial representations of glass-making. The earliest relic brought from Egypt bears the inscription of Thothmes III., and was made 1500 B.C. The Coptic name of glass, *badjiein* or *abadjein*, and some variations of this word have no connection with Semitic words. The Arabs have given a wide extension to the word *zajaj* or *zagag* among Mahometan nations. But among the Aryan Mahometans in India, in Persia, in Kurdistan, as also among the Turks, glass is called *shish*. In Hebrew *shish* or *shayish* is the name of marble, and may eventually have been used in the signification of glass. Whether glass was in the earliest days manufactured in Palestine or not, glass vessels must have been known to the Jews. This is not solely to be inferred from the circumstance that the Palestine Exploration Fund has brought to light numerous fragments of glass vessels, for such vessels may have been made at a late period, but it is an indubitable fact that the Phœnician traders, according to the testimony of the Bible (Proverbs xxxi., 24, and Hosea xii., 8), constantly came to Judea to offer their wares. Israelite women liked to adorn their necks with glass beads. Specimens of such ornaments occur everywhere; note for example the specimens found in the tombs of the Egyptians and the Etruscans. Among the treasures which Dr. Schliemann discovered at Hissarlick, the so-called site of Troy, and again in the graves of Mycenæ, Egyptian or Phœnician glass beads have been found. Even beneath the lakes of Switzerland, where the pile buildings of ancient inhabitants have been brought to light, glass beads were discovered, which none but Phœnician traffickers could have carried to Switzerland, just as they brought them into the lands of the ancient Britons. No doubt can therefore exist that the Hebrews of the earliest date were fully acquainted with articles made of glass.—EZRA.

76. MONOGRAMS.—We take pleasure in publishing the annexed **monograms: G. B., M. D. H.,**







L. F. R., W. A., W. W., M. G. T., and G. E. T. We have received several other monograms, which are simply duplicates to those presented.

Queries.

77. CORNER SHELVES.—Would like some instructions regarding a corner bracket or corner shelves, which I desire to have put up in a room. I desire to have them neat and well-finished, but not too expensive. Any one who has had any experience in these matters will oblige me very much by giving me such information as they may think I may need.—JESSIE S.

78. CATAMARAN.—In the April number of the YOUNG SCIENTIST there is an article on cheap boats, and in it is mentioned a catamaran, which is recommended by the writer as being cheap, fast and safe. Can you or Mr. O'Grady give any further information regarding this kind of a craft? If you would publish some it would confer a favor on—LAKE ERIE.

79. SOFA AFGHAN.—I am about to make a sofa afghan. I want some ideas as to length, colors, and stitch best adapted for the purpose; also quantity of wool necessary, and what kind. Will some one who has had satisfactory results kindly give me the benefit of her experience?—CONSTANCE.

80. FRAMING PHOTOGAPHS.—I have a photograph which I desire to frame myself, but am at a loss in deciding how to frame it. I can do the manual part of the work well enough, but would like to have a few hints as to materials and arrangement. Would any of your readers be kind enough to assist me?—BIG BOY.

81. LANGUAGE OF PRECIOUS STONES.—I thank you very much for answering my query (21) regarding trees and flowers, and am encouraged to still further trespass on your good nature by asking for a reply to the following question. What is meant by the "language of precious stones?"—MATILDA.

82. MONOGRAMS.—A. M. wants a monogram of the above initials for inlay work, and asks Bostonian if he will kindly design one and publish it. Monograms are also desired for E. H. H., J. H. J., L. H. H., and T. T. H.

83. FORCING PLANTS.—H. H. Field desires to know how plants may be *forced* to bloom and to early maturity.

NOTE.—"H. H. Field" might get a more satisfactory answer if the variety of plants wished to mature had been named. One way to produce *blossoms* in an early stage of a plant's growth is to cramp the roots by potting in a small pot, pinch off buds that appear weakly, water with liquid manure, and give sunshine plentifully. Some plants run all to leaf when fed with mixed drinks, and need starving to make them bloom. H. H. F. can see that to bring a lettuce, a lily, and a lilac-bush to maturity would require three distinct modes of treatment.—E. M. H.

Market Report.

Retail Prices.

IMPORTED CAGE BIRDS.

Canaries, *Belgian*, per pair	$6.00 to 15.00
" *French*, per pair	6.00 to 15.00
" *German, Hartz Mts.*, each	2.50 to 10.00
Gold Finches, each	1.50
Gold Finch (mules), each	2.50 to 5.00
Bull Finches, not trained, each	2.50
Bull Finches, trained to sing two tunes, each	10.00 to 40.00
African Finches, per pair	2.50 to 5.00
Chaffinches, each	1.50
Talking Mino or Mina	10.00 to 25.00
Linnets, each	1.50 to 2.00
Linnets (mules), each	2.50 to 5.00
Green Linnets, each	1.50
Java Sparrows (blue), each	1.50
Java Sparrows (white), per pair	6.00 to 8.00
English Sparrows, per pair	1.00
Siskins, each	1.00
Gray Cardinal, each	4.00 to 5.00
Nightingales, each	8.00 to 25.00
Japanese Nightingales, each	5.00 to 10.00
Thrushes, each	5.00 to 7.00
Skylarks, each	5.00
Troopials, each	7.00 to 12.00
European blackbirds, each	5.00 to 7.00
Black-caps, each	4.00
Starlings, each	4.00 to 6.00

PARROTS.

Gray Parrot	10.00 to 15.00
Single Yellow-Head Parrot	8.00 to 12.00
Double Yellow-Head Parrot	10.00 to 15.00
West Indian "	4.00 to 5.00
Cockatoo (white)	18.00
Australian Shell Paraquets, per pair	6.00
"Love Birds," African Paraquets, per pair	6.00
West Indian Paraquets, per pair	3.00 to 5.00

All birds that are accomplished singers or talkers bring high and "fancy" prices. Parrots are rated by the number of words, sentences, and tunes they have learned.

AMERICAN CAGE BIRDS.

Canaries, each	2.50
Mocking Birds, females, each	1.00
" " singers	12.00 to 25.00
Robins	2.50 to 5.00
Blue Birds ("Blue Robins") each	1.50
Indigo Birds, each	1.00
Nonpariel, each	1.50 to 2.00
Virginia Cardinal, each	2.50 to 3.00
Bobolinks, each	1.50 to 2.00
Yellow Birds, each	1.50 to 2.00

Prices Paid by Dealers.

Robins, per hundred	12.00
Blue Robins (Blue-Birds), per pair	0.35
Indigo Birds, each	0.50
Bobolinks, per dozen	3.00
Yellow-Birds, per hundred	12.00
Orioles, per hundred	25.00 to 35.00
Virginia Cardinals (Red-Birds), each	0.75 to 1.00
Nonpareils, each	0.75
Blue-Jays, each	0.35
Scarlet Tanagers, each	1.00
Red-Winged Starlings, or Black-Birds, each	0.25
Woodpeckers ("High-Holers"), each	1.00
Partridges, each	1.50
Cranes, each (according to variety)	10.00 to 20.00
Wood-Ducks, per pair	2.50
Wild Bronze Turkeys (one cock, two hens)	10.00 to 15.00

FANCY POULTRY.

Guinea or Pea-Hens	12.00
Pheasants, *English*, per pair	20.00
" *Golden*, "	35.00
" *Silver*, "	30.00
Pea-Cocks, per pair	20.00 to 75.00
Bronze Wild Turkeys	15.00 to 20.00
White Turkeys	10.00 to 15.00
Bantams, trio	3.00 to 10.00
Ring-Doves, per pair	1.50
Pigeons, *common*, per pair	0.75
" *all white, common*, per pair	1.00

BIRD FANCIERS' MATERIALS.

Breeding Cages (double)	1.50 to 4.00
Trap Cages	0.75
Wire " painted	0.50 to 4.00
Wood and Wire Cages	1.50 to 4.00
McAllister's Mocking-Bird Food, 1lb. jar	0.35
" Canary-Bird Food, 1lb. box	0.20
" Mixed Bird Seed, 1lb. box	0.10
" Extra Silver Bird Gravel, qt. box	0.10
McAllister's Prepared Fish Food, per box	0.10
" Song Restorer, for birds, per bot.	0.25
McAllister's Bird-Lice Destroyer, in patent bellows box	0.25
McAllister's Bird Lime, per box	0.25
Cuttle-Fish Bone, each	0.05
Meal-Worms, per hundred	0.40
Nest Boxes, wire and tin	0.10 to 0.15

QUADRUPEDS.

Terriers, *black and tan*, each	5.00 to 30 00
Terriers, *Scotch and Skye*, each	5.00 to 30.00
Newfoundland Pups, each	10.00 to 15.00
Pomeranian or Spitz "	5 00 to 15.00
Greyhounds, *English*, "	10.00 to 25.00
Greyounds, *Italian*, "	10.00 to 30.00
Guinea-Pigs, *common*, per pair	1.50
" " " " large	1.50 to 3.00
Guinea-Pigs, *all white*, "	2.00
Squirrels, *gray*, "	5.00
Squirrels, *all white* "	15.00 to 25.00
Squirrels, *flying* "	3 00 to 4.00
Squirrels, *small red* "	2.00
Rabbits, *common*, per pair	1.00 to 2.50
Rabbits, *fancy breed*, according to age and purity of breed, per pair	3 00 to 15.00
Ferrets, *English*, "	15.00
Raccoons, each	4.00 to 5.00
Cats, *Maltese* (males), each	5.00
" " (females), each	3.00
Cats, *Albinos, pink or blue eyes*, each	3.00 to 5.00
Rats, *white China, pink eyes*, per pair	1.50
Rats, *piebald*, per pair	1.50
Mice, *white, pink eyes*, per pair	0.50
Mice, *piebald*, per pair	0.50

Prices Paid for Pet Stock by Dealers.

Guinea-Pigs, per pair	$0.40
Squirrels, *gray*, each	0.50
Squirrels, *flying*, per pair	0.75
White mice, per pair	0.15
Monkeys, according to variety	15.00 up.

MARINE AQUARIA STOCK.

Purple Bermuda Anemone	2.00
Fringed Sea Anemone, Medium-sized specimens	1.50
White-Armed Anemone	0.50
Small Orange "	0.10

SHELLS.

Collections of small "cabinet" shells for schools, private cabinets, range from $5.00 to $50.00.

Mother-of-pearl shells, for painting, 75 cts. to $1.50.

Single specimens of cabinet shells range from 15 cts. each to $3.00.

Masses of corals, 25 cts. to $3.00.

Green snail and cowry, with the Lord's Prayer engraved on them, 50 cts. to $2.50 each.

Conch shells, for mantels or hearthstone ornaments: West India Conch, 25 cts.; East India Yellow Helmet, $1.00 to $2.50; Bahama Black Helmet, 50 cts. to $1.50; Bahama Hatchet Helmet, 50 cts. to $1.25. These shells are also for cameo engraving. Zanzibar Cameo, 25 cts. to $1.00.

Ground and polished shells: New Zealand Green Ear, 50 to 75 cts.; New Zealand White Ear, 50 to 75 cts.; Japan Black Ear, 50 cts. to $1.00; California Red Ear, 75 cts. to $1.25.

Fine shells for fancy work, according to colors and variety, per quart, $1.00 and up.

Fancy Wood for Scroll Sawing.

The prices given for the various woods used in this work are for the best of qualities of seasoned material, planed on both sides, ready for immediate use. They can be furnished in quantities to suit purchasers. Prices are by the square foot, and vary according to thickness of material.

For all information on this subject, as to reliable dealers, etc., etc., send postal card to Young Scientist, When desired, the goods can be sent through this office, but in all cases remittances must accompany the order.

EXCHANGES.

Only those who are *yearly* subscribers, and whose names are entered on our books have the privilege of inserting exchanges.

Exchanges must be on separate slips of paper or postal cards. If mixed with business matter in letters or cards they are filed away and never reach the printer.

Exchanges must not exceed thirty words.

Buying and selling belong to the advertising department.

We reserve the right to omit the exchange column, when we have not room for it, and the amount of space at our disposal will regulate the number of insertions given to each *exchange*, the preference being always given to those who have not previously used our columns.

"Crystallography" (40c.); "Electricity" (40c.); "Selection and Use of Microscope," abridged, (30c.) Either in exchange for "Workshop Companion," or two for "The Microscope," by Ross, or offers. C. H. Denniston, Pulteney, N. Y.

A printing-press, chase 5½ by 7 inches, in good order; will exchange for a large self-inking press or type. A. W. Barrett, Canajoharie, N. Y.

Home Medical Battery, cost $7; Lemair's Field-Glass, No. 2202 of Queen's Catalogue, cost $15.50; Achromatic Spy-Glass, power 25 times. To exchange for books or offers. Emerson Heilman, Heilmandale, Pa.

Silver watch, key-winder and Home Works, for good microscope or offers. Wm. Hodgson, 128 Mangin St., New York City.

A small collection of coleoptera, comprising 100 species and 300 specimens, all correctly named, in exchange f r bird-skins, insects, books, or eggs. Emil Laurent, 621 Marshall St., Phila., Pa.

A small magic lantern, Ruby pattern, with twelve slides, for a good book on Entomology, with illustrations. Willie R. Hotchkiss, Morrisdale Mines, Clearfield Co., Pa.

Wanted, Thompson's "Witchery of Archery." Must be in good condition. Write before you send. J. Anthony, Jr., Coleta, Whiteside Co., Illinois.

A telescope worth $3.50, for a self-inking printing-press and outfit; chase not less than 2½ by 3½ in. Eddie Judd, 260 Connecticut St., Buffalo, N.Y.

To exchange for offers: $20 scroll-saw, Seneca Falls make, $4 Bailey circular plane, set of Auburn metallic planes, brass-bound four-foot rule, fourfold, Traut's patent combined plow, dado, etc., cost $7. F. A. Rappleye, P.O. Box 12, Farmer Village, Seneca Co., N.Y.

Bee Hive wanted; one of the old-fashioned straw "skeps"; say what you would like in exchange. Apis, care of Young Scientist, 294 Broadway, N. Y.

A first-class type writer, in excellent condition, cost $125.00, to exchange for good microscope, telescope, or valuable scientific books; send full particulars. A. B., Box 114, Lewiston, Maine.

A $30 stencil outfit (Spencer's) for a self-inking printing press in good condition, chase about 6 x 9; rich ores and minerals of Idaho for scientific and instructive books, printing press, type, etc. J. P. Clough, Junction, Lemhi Co., Idaho.

Wanted pyrites of iron from Colorado gold mines in exchange for sea shells and other gems; send list of what you have to exchange. S. Ferguson, Eureka Springs, Arkansas.

A banjo in good condition, two pairs of rosewood bones, three splendid games, and a fine set of drawing instruments, for a good cornet, viola, violincello or double bass. L. B. Hill, Kalamazoo, Mich.

Scientific specimens of various kinds for same. Geo. E. Frazier, Caldwell, Ohio.

Lester W. Mann, Randolph, Mass., Box 162, has Demas scroll saw, lathe and tools, emery wheel; $20 worth patterns; Smithograph; large harmonica, cost $1.75; novelties in seeds; for large self-inking press or offers.

10 volumes Chambers' Encyclopædia, American Book Exchange edition (cloth); Bonanza printing press, chase 3 x 5, card type, ink roller; spyglass, power 10 times; for French triplet, 1-5 in., or offers. H. P. Nichols, P. O. Address, Bridgeport, Conn.

A good telescope, also foot-lathe and saw combined, each worth $10 00, for shells, fossils or relics. Independent, Conncautville, Crawford Co., Pa.

Birds' eggs to exchange for others; send list of what you have to exchange. Emil Laurent, 621 Marshall St., Philadelphia, Pa.

Twelve or fifteen volumes of the American Agriculturist to exchange for scientific books or offers. W. H. Osborne, Chardon, Ohio.

J. D. Rice, P. O. Box 473, Trenton, N. J., would be pleased to correspond with mineralogists for the purpose of exchanging specimens and ideas.

To exchange, my collection of nearly half a thousand rare postage stamps with catalogue, for second-hand Flobert rifle; must be in good condition. H. E. Whitman, Station M, New York.

I have a large assortment of foreign stamps to exchange, also Confederate money. Collectors send sheet and I will return it with mine. Box No. 2, Coeymans, N. Y.

Electric bell engine, cost $15; pair of analytical scales, cost $10; pair of Bell Telephones to exchange for a printing press, watch or offers. Geo. N. Bigelow, Box 754, Palmyra, N. Y.

Any person wishing to trade bird's eggs may apply to me and I will send them my list of bird's eggs. I have only a few at present, but am receiving a number every month. A. G. G., Box 26, Summit, New Jersey.

Minerals of Idaho for Standard Works on the Horse—Wallace's Registers and turf journals. Wanted, also other useful books, bound and in good condition. Many varieties named in my list. J. P. Clough, Junction Lemhi Co., Idaho.

To exchange for offers first four (fifth when completed) bound volumes of YOUNG SCIENTIST. J. N. Brooks, P.O. 1468, N. Y. City.

Wanted engraver's tools with book of instructions, for a Victor Press, with cabinet, 2 type cases, type, ink roller and furniture complete; perfectly new. L. Warren, 72 Cumberland St., Brooklyn, N. Y.

A Fletcher Foot-Blower, cost $5, as good as new; will exchange for a Cushman, 2 in or up scroll chuck, or other make; will give a satisfactory trade on the difference in price, if any. Louis Lutz, St. Clair Street, Toledo, O.

I have a lot of "Galaxy" (magazines) which I would like to exchange for an air rifle in good condition, a collection of birds' eggs, or offers. W. B. Greenleaf, 480 La Salle Ave., Chicago, Ill.

I have a Mechanical Telegraph with book of instructions, books, etc., which I wish to exchange for good microscopical objects, mounted on 3 x 1 slips. Address, with list, J. H. Frey, Millersburg, Ohio.

To exchange, "How to Use Microscope," Wells' "Natural Philosophy," and many other books, chemical apparatus, etc., for good photographic camera, and lenses. W. H. Weed, 254 Putnam Ave., Brooklyn, N. Y.

Wanted "Quimby's New Bee Keeping," for "Our Own Birds of the United States," by W. S. Baily; new. Joseph Anthony, Jr., Colota, Whiteside Co., Ill.

Wanted a good book in anatomy, in exchange for a book on chemistry, or for story books. A. G. G., Box 26, Summit, New Jersey.

A German-silver trimmed, patent lined, cocoa flute, cost $4, in good order, for good spy-glass, photo-material, or offers. Ewing McLean, Greencastle, Ind.

I have some fossil shells from the west bank of the Mississippi, to exchange for Indian relics. A. W. S., 187 E. 71st St., N. Y.

I have a magic lantern, Ruby pattern, nearly new, and 5 views; also "Our First Century," bound in leather, cost $7; state what is wanted in exchange. I. N. Spencer, Box. 217, So. Manchester, Conn.

First-class telegraph instrument and attachments, and "Wood's Botany," for bound volumes of periodicals, books, or offers. H. P. Albert, Anderson, Iowa.

Wanted a book on treatment and care of canary, also breeding of same; will give in exchange book named "Market Garden, Flower Garden and Bees," or 40 "Scientific Americans" or "Seaside Libraries;" want also old books. M. J. Mulvihill, Norwalk, Conn.

HOME ARTS.

VOL. VI. NEW YORK, SEPTEMBER, 1883. No. 9.

Canaries: How to Keep and Breed Them.—II.

BY GORDON STABLES.

YOU can turn the hen into the breeding-cage—it will be her home; but the male bird must be kept in another cage and in another room. And in this manner they must be kept separate until the breeding season, namely, about the second week of March, if the weather be mild and fine, but not until the last week if it is not so. If you do not attend to this hint illness of the hens and death of the nestlings may be the result, and you will have your labor lost and your hopes all blighted.

Now, some breeders, before turning the male bird into the breeding-cage, place the two cages in the same room and in sight of each other for a day or two. You may do this or not, as you please. I have sometimes thought it did good, but such great authorities as Mr. W. A. Blakston think it quite unnecessary. Anyhow, after you have turned in your birds, in nine cases out of ten they will soon become friendly enough, and the male will commence to feed his mate on the egg and bread-crumbs which you now specially prepare for them. Give them two or three teaspoonfuls of this fresh every day; and it may be as well to mix with it now and then a little maw-seed or scalded summer rape, and now and then a little crushed hemp-seed. A portion of green food will also do good, either groundsel or chickweed. The bread-crumb should be stale, but not old. Lunch biscuit is perhaps as good, if not better, than bread, and a morsel of sponge-cake may be placed between the bars of the cage. Your birds are now properly paired, and matters, we trust, will go on swimmingly. By-and-by the hen will begin to lay, and it is a good plan to remove the egg very carefully each morning, placing it most gently in cotton wool, and substituting, if you

choose, an ivory nest-egg, although this is not at all essential. As soon as the third egg is laid you may restore the others, and the hen will then sit. As a rule, the male will be very kind to her, but instances occur sometimes of males being very troublesome to their mates during sitting time; he must in a case of this kind be kept by himself in the other compartment of the breeding-cage.

The eggs take thirteen days to hatch from the time the hen has been set; but when the nestlings do come out both parents are prouder far than princes, and the male will take at once to assist the hen in rearing their darlings.

You must continue the same food for weeks, until, indeed, the young birds are able to feed themselves with the ordinary bird seed.

It will be as well to keep your breeding-cage in your own room. Always approach the cage gently, and never make startling movements or noises, especially when the hen is sitting. As I have already said, in order to get good results your birds must be each of them in good health at the time of pairing. How are you to know this ? By their actions. A healthy bird is a happy bird—happy, and jolly, and frisky, with a "ten-horse power appetite." See well to the behavior of Mr. Canary after the young are hatched, for there are such anomalies as cannibal canaries.

See, too, that the hen does not sit too closely on the birds, or she may sweat and kill them. If she does this, probably the best plan will be to remove the male, so that she will be compelled to leave the nest to feed herself. Some recommend giving the hen a bath; others place bits of stick about the thickness of stocking-wires inside and across the nest, but not touching the birds; while others, again, think there is no cure for "sweating," as it is termed. My own humble opinion is that the hen herself in such cases cannot be in the best of health, and a rusty nail placed in the water by way of tonic, or a few drops of the tincture of steel, cannot do harm and may do good.

Wean your young birds gradually from the egg-food. I had almost forgotten to say that the breeding-cage ought to contain a good sprinkling of sea-sand at the bottom of it, and some breeders add morsels of old lime.

If you have your breeding-cage in your own apartment you will be sure no one meddles with or frightens your pets, and you will be better able to see that they have always a good supply of fresh water. Do not place the cage in a draught, nor in the sun, but in an elevated warm corner; keep it very clean, and also keep the apartment well ventilated. If the sun shines in at the window, it will do good to place the cage for a short time daily in its rays, but do not forget and leave it there.

Talking of cleanliness, the bird's perches ought to be always free from dirt; so should the feet of your canaries, and the claws must not be suffered to grow long enough to endanger the safety of the eggs.

There are many, many things connected with breeding that I need not tell you here, but which experience will teach you; and whatsoever experience teaches one he is far less likely to forget.

Sometimes a hen canary has a difficulty in depositing her egg; she becomes what is called in common parlance "egg-bound." This arises from a want of tone in the bird, or power of expulsion. To more immediately assist her, she ought, after sitting some time, to have the after-part of the body held over steam—not too hot, remember, else you may destroy her. Or the parts may be oiled with a feather and the steam-bath afterwards tried.

I have advised you to procure strong, healthy parents of the variety you have a fancy for, and of the best prize strain; you will thus have a chance of breeding something really good and worthy of exhibition. But I warn you not to be over-sanguine. It is difficult to breed anything of rare excellence. Anyhow, you can do your very best, and live in hope.

The breeding season commences, say, in the middle of March. Well, it must not last over five months. Make this a rule, and stick to it.

Be very careful with your feeding, and

attentive to the cleanliness of all the bird's surroundings during the breeding season, remembering that the food must be nourishing. When a hen gets delicate it will be judicious to give her a month's rest and a tonic.

The temperature of the apartment where your breeding-cage is placed should be only moderately high, and it should be equable. Never keep birds in a room that is heated by gas, or those terrible abominations called petroleum stoves.

The less luxuriously canaries are fed in ordinary times—when not breeding—the better. Birds of this kind, if kept clean and nice, thrive best on simply what are called the white-and-black canary-seeds. See that they are good and fresh, and free from dust. You may let them have a tiny morsel of loaf-sugar, but the fewer delicacies the better. Be careful to wash out the glass every morning before you place the fresh water in it, and let the bird have a saucer bath every day if it be so minded.

Green food should not be forgotten, but always give it fresh. Groundsel and chickweed are probably the best.

(To be Continued.)

Amateur Carving.

LAST month we gave several examples of amateur carving, executed by some of the students in the Cincinnati School of Design, under the superintendence of Mr. Ben. Pitman. This month we exhibit two other examples executed by students in the same school. The examples shown are simply surface carvings, and are suitable for base-boards, skirtings, or any flat members. The designs are easy to execute, and may be wrought in pine, cherry, oak, walnut, or other suitable wood.

Fig. 1 shows a flower pattern conventionally treated. If handled with boldness, this design makes a very effective baseboard, and if finished as described in our last number, would be as pretty as effective.

Fig. 2 is equally adapted for baseboards, mantel friezes, or window cornices. It is easier to execute than Fig. 1, and therefore more likely to be adopted by the amateur. Care should be taken on the straight lines, for nothing spoils carved work more than broken straight lines or ragged edges.

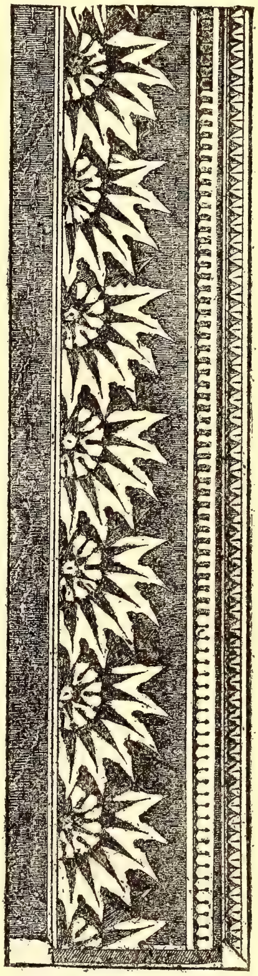

Fig. 1.

CARVED BASEBOARD—FLOWER PATTERN.

Figs. 3 and 4 show two designs of carvings in Moresque style, which is becoming very popular just now. The Mahometan religion forbade ornament, and hence we seldom, if ever, find the slightest effort at natural carving in Moorish architecture or furniture. This, at first thought, would seem to indicate

that the Moresque must be a very cold and geometrical style indeed. But such a notion would be due more to our own freedom of fancv than to any serious restriction actually weighing upon the Mahometan carver. The religious law alluded to in no measure deteriorates Moorish production. On the contrary,

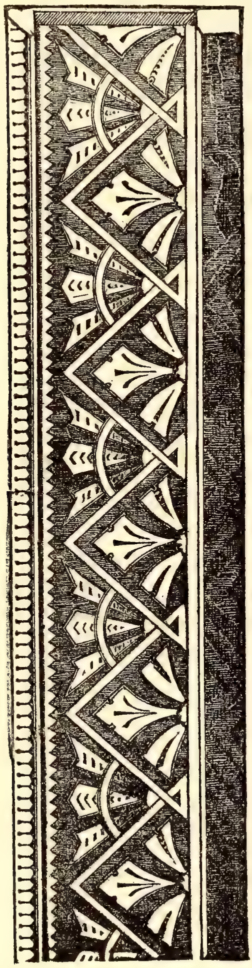

Fig. 2. CARVED MANTEL FRIEZE, BASEBOARD, DOOR-RAIL, OR WINDOW CORNICE.

it has led the Eastern carver to search elsewhere, and has forced him to think more deeply than he would have done had he been free to simply copy nature. Such observation as the Moors indulged in naturally improved their taste, and brought to their notice many methods of procedure which, had they been as free to choose as we are, they, perhaps, would never have known. Thus prevented from copying nature in her integrity, they the more eagerly studied her set laws, and upon these founded one the most beautiful styles of decoration that the civilized world has known. Perhaps the most useful law of nature which the Moors followed in their surface decorations is that of radiation from a parent stem. Every part of the design can be traced to its branch and root, to whatever distance the decoration may go. There is no stopping of the design at one place and starting it again a little higher up, and, what is also of great importance, no foreign or incongruous matter is ever introduced. Vases and festoons, figures and masks, appear in other styles, and are all very well in their way for decorative purposes. It is an open question, however, whether a vase carved upon a panel, with a bunch of healthy flowers growing out of it, is not a little too far-fetched to be classed as high art. The Moors never so indulged their fancies. They commenced their design from the ground, and then, by bending the branches into elegant curves, and filling the interstices with leaves and buds, they generally capped it with some form, either floral or astral.

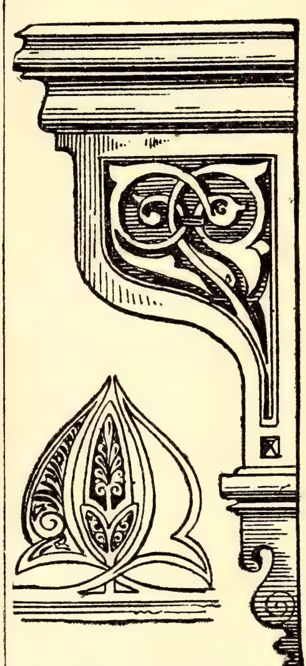

Fig. 3.—BRACKET.

Fig. 3 is a bracket upon which the carving is peculiarly Moresque. There is one

scroll springing from the lower part, swelling outwards and folding inwards. At the completion of the scroll a new member is started in the form of another scroll, which is turned in an opposite direction; then the two scrolls are tied together, and the leaves are thrown out so as to fill up the empty spaces.

Fig. 4 is a drawer front. The design is composed of geometrical bandings overlapping each other and forming panels which are carved, incised or left plain. In the centre, space should be left for the handle.

This design may also be used as a panel design for doors or wainscot, or other suitable places.

Fig. 4.—PANEL OR DRAWER FRONT.

The bracket (Fig. 3) is capped with a moulding consisting of the ogee and chamfer mouldings. These two members are most frequently met with in good work. In preparing Moorish mouldings it is well to avoid the more common curves, such, for instance, as can be struck out with a compass from one centre like the quadrant of torus, and rather to adopt the more subtle lines, such as ogees and the conic sections. We have seen Classic mouldings employed upon modern Moorish work; but although they may suit the eclectic taste of some, they are certainly not true to style. We hope that these few sketches and suggestions will be useful to those amateur carvers who are anxious to become acquainted with Moresque Art.

Glass Making in Ancient Times.

IN the various branches of industry which has been attributed to the ancient Egyptians, superiority is particularly to be noticed in the case of their glass manufactures, from the specimens which have come down to posterity. Thus, in the monumental works executed in the time of the Pharaohs, we find, in addition to glass vases of ordinary shape, small vases (both dull and transparent) ornamented with the richest and most diversified colors, which bear witness to considerable progress in artistic decoration. The form of the lotus-flower in outline and other tasteful ornamentation, in blue on a white ground, is found in these specimens; likewise jars with waved or zig-zag lines in white on blue, or in yellow on a light blue ground, have been found amongst specimens of ancient Egyptian ware.

In giving some comprehensive details on the subject, the *Revue Industrielle* alludes to a small terra cotta figure representing a lion, which may be seen in the Louvre, the eyes of which (formed of incrusted glass) have a life-like expression about them. That the Egyptians were acquainted with the art of glass-blowing would seem established by the sculptures found in the grotto of Beni Hassan-el-Gadim, dating from a period seventeen centuries before the Christian era. In these the process of glass-making is represented in a clear manner. In the vicinity of the Salt Lake there have also been found remains of an ancient glass-making establishment. The industry seems, however, to have concentrated itself in the vicinity of Alexandria. According to Strabo, the glass factories did not require to obtain the necesary materials for their industry from the territory of the Phœnicians, but they used a so-called "glass-making earth," found in Egypt, and without which the manufacture of glass so rich in ornament and in variety of color would have been impracticable.

Etruscan glass decoration, it is remarked, has in some points a resem-

blance to the artistic ornamentation employed by the ancient Egyptian artificers. Chemical analysis shows that the bluish tint so often to be seen in Etruscan glass is produced by cobalt, and this kind of manufacture is stated to have been usual in various important factories.

The fineness of the ware produced in ancient Rome is said to have been marvellous. A glass-maker, who lived during the reign of the Emperor Nero, produced glass vessels of wonderful lightness, which commanded as high a price as about $150 each. Martial speaks of them as "glassy vapor." There is a specimen of this delicate kind of manufacture in the Rouen Museum. It is a drinking vessel of white glass with a handle. Its circumference is 13 inches, and its height 4 inches, while its weight is said to be a fraction under 2 oz.

The Blue Process.

BY JAS. MACDONALD, M.E.

THE introduction of the blue printing process for duplicating drawings, has caused a decided change to be adopted in their preparation. The common practice now is to construct the drawing in fine hard pencil lines, and trace them without being "inked in" on tracing cloth or paper, as the drawing to be copied must be made on transparent material.

The blue printing process is very simple and comparatively inexpensive, and may be practiced by anyone who can procure a piece of plate glass large enough to cover the drawing to be copied. The tracing should be made in good strong black lines. The figures, indicating dimensions, must also be put on plainly; the dimension and centre lines should always be broken or dotted, preferably in red, so that they may be distinguished from the other lines of the drawing, on the blue print. In working drawings, all the dimensions must be given in figures, as no measurements can be made on the blue print. The paper shrinks or changes its shape so much when being washed, that it is no longer a duplicate of the original, so far as size is concerned. The tracing must be kept clean, flat and smooth to insure good work, as any creases or folds in the material will be reproduced in the print. The kind of paper to be used in the blue print, will depend on the use to which it is to be put. Almost any kind of paper may be used, so long as it is white; but for copies of drawings that are intended for office use, to be filed away for reference, or that may be sent through the mails, it is advisable to have thin tissue paper. This will stand a moderate usage, and will fold into a small compass, and may be placed in envelopes if necessary, and filed. For prints that are to be used as working drawings in the shop, or on buildings, a thick heavy white paper is best.

The chemicals necessary for preparing the paper and their proportions are as follows: $1\frac{7}{8}$ oz. citrate of iron and ammonia; $1\frac{1}{4}$ oz. red prussiate of potash. To be mixed with 16 oz. water. The iron and potash should be thoroughly dissolved in the water, and the mixture filtered through bibulous paper. The operation should be performed in a dark room. Keep the mixture from the light. To prepare the paper, it is laid flat on a table, and with a soft brush the surface is coated evenly with the chemical preparation, care being taken to avoid "streaking" or brush marks, as any unevenness of this kind will show in the print. Colored lights, such as from a lamp or gas jet, will not affect the preparation, but it must be kept from the sun or electric light. To take the print, the prepared paper should be laid with the chemical side up on a flat soft cushion, which may be a thick blanket spread evenly on a table; on this the tracing is placed with the blank side next to the paper, and both covered with the glass plate. An exposure of from 4 to 30 minutes, will be necessary according to the intensity of the sun light. If it receives the direct rays of the sun, the paper will turn iron grey in color, after about four or five minutes, and then must be removed quickly. It may now be placed against an inclined surface, and be thoroughly washed by directing a

stream of water against the printed side. In a few moments the chemical that has been covered by the black lines of the drawing will be washed away, leaving the white paper exposed, which will represent the lines of the drawing; the surface of the paper which *has* been exposed, will retain the chemical, and in various shades of blue, according to the amount of time it has been exposed to the light. It is now only necessary to hang the print up, and allow it to dry to be ready for use.

Something About Saws.—VII.

BY "OUR NED."

IN the July number of the YOUNG SCIENTIST I described and gave several illustrations of clamps and other devices for holding and sharpening saws. Perhaps I ought to have shown and described the "saw sets" shown in the present article, for the setting of a saw must be done before the filing takes place, otherwise the teeth will have their fine cutting edges broken away. Every amateur who uses a saw should make a note of the above hint, and in no case set a saw after it has been newly filed.

Sometimes, if a saw is very much out of order, it is roughly filed, so as to give the teeth the right form, pitch and size, before setting; but when such is the case, the saw, after it has been set, is again filed, and the teeth brought up to proper working order.

When a saw is in very bad shape, similar to the illustration shown at Fig. A, in the February number of this journal, it cannot be "set" accurately until the teeth are made the right shape and size; and this can only be done by first jointing the edge of the saw with a fine flat file, cutting down the points of the teeth until the jointing file touches every one of them, and the line of teeth, from handle to point, is straight and regular. When this is done to the satisfaction of the operator, then the rough filing may take place, and proper form, size and pitch given to the teeth, after which the setting process may be performed, followed by filing the teeth to working order.

There are a great number of "saw-sets" in the market, each claiming for itself special merit, but I am of the opinion that there is no tool offered for sale that will set a hand-saw as good as the old-style hammer set, when in the hands of an expert setter.

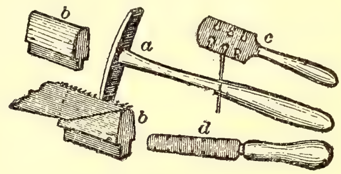

Fig. 1.

Fig. 1 shows the kind of hammer, *a*, the sawmaker generally employs when setting hand-saws. The saw being laid nearly flat, with its teeth along the ridge of a rounded-edged anvil or stake, *b b*, held in the tail vise; the angle is in great measure determined by the curve of the stake, which is, for fine-toothed saws, considerably pointed. Half the teeth having been bent, the saw is turned end for end, and the intermediate teeth similarly treated.

The sets *c d* are commonly employed by the users of saws, requiring less skill to give the proper inclination to the teeth—*c* is used for large, and *d* for small saws. They consist of narrow blades of steel, with notches of various widths, to accommodate different thicknesses of blades. The saw is held between clamps, the alternate teeth inserted a little way into the notch which they most nearly fit, and bent over to the proper angle by pressing the handle of the tool; the operation is then repeated on the intermediate teeth.

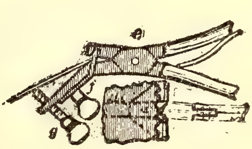

Fig. 2.

Sometimes saw-set pliers, *e*, Fig. 2, are used. These require two adjustments:

one for setting the jaws to the thickness of the teeth, which is effected by a stop held by the thumb-screw *f*; and the other for determining the angle to which the teeth shall be bent, which is regulated by the thumb-screw *g*.

Fig. 3 is so constructed that it may be stuck in a hole in the work-bench. The punch *C* is pivoted to the stock, and is struck by a hammer. The gauge *D*, against which the points of the teeth rest, graduates the position of the saw in accordance with the length of the teeth and in relation to the hammer. The blade rests on *H*, whose vertical adjustment determines the degree or *set*.

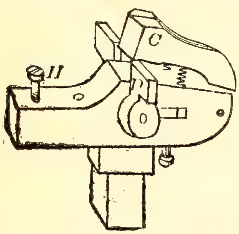

Fig. 3.

Fig. 4 is another form of bench implement, in which the punch is placed in a socket of the adjustable spring. The saw-rest has an inclined lower side, and the brackets vary in elevation to suit, so that the rest can be moved endways to alter its elevation and the set of the saw, such movement not destroying the horizontality of the upper edge of the rest.

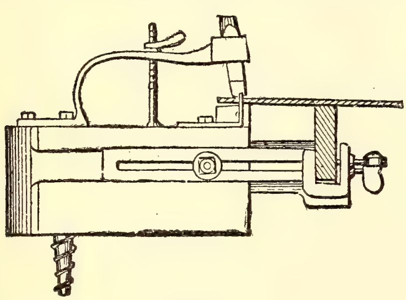

Fig. 4.

Fig. 5 shows another set suitable for putting in a bench. It is on the hammer principle, and can easily be adjusted to give the requisite set by raising or lowering the two set-screws.

Hand-saws may be set very well with a small punch or nail-set. Place the blade of the saw on a piece of hard wood; then take a small punch, putting the flat end of it on the tooth to be set; strike the top of the punch a short, sharp blow. Examine the tooth; if all right, go over the other teeth in a like manner, giving each tooth the same sharp blow. If the set is too much, strike lighter; if too little, strike heavier. Go over every other tooth first; then turn the blade over and repeat the process.

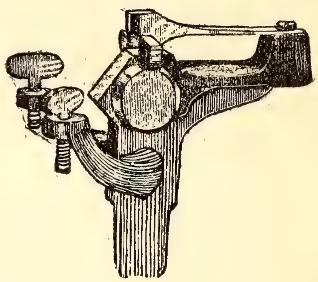

Fig. 5.

Sufficient has now been said on the subject of saws, in this journal, to enable the amateur to file his own saws tolerably well; but should he need further information he may obtain it from a work recently published by the proprietors of this journal, entitled "Hand-Saws, their Use and Abuse; How to Select and How to File." Price $1.00. I have drawn freely from the work in the foregoing papers.

Breguet.

IN days gone by, the clepsydra, the sun-dial and the hour-glass were used to record the flight of time. The clepsydra was a transparent case filled with liquid which slowly trickled through an aperture in the bottom, the receding waters marking the passage of the hours, which were indicated by characters traced upon the glass. This was the oldest and simplest form of the clepsydra; and the hour-glass was but a modification of the same principle, sand being substituted for water. The advantages of the hour-glass over

the clepsydra were two-fold: first, the sand would neither freeze nor evaporate; second, when the glass was full it would run little faster than when it was empty. The term "clock" originally signified "bell," and as the French use it to-day ('*cloche*'), still retains that meaning.

For several hundred years after their invention they were exceedingly rough and very irregular in their movements. To Galileo is due the discovery of the pendulum, which added greatly to the accuracy of time-keepers

One of the most celebrated clock-makers of the world was one Breguet, a native of Neuchatel, Switzerland. While yet very young, this remarkable individual was sent to Versailles for the purpose of learning his trade as a horologist. He there served a regular apprenticeship, and his advancement is said to have been most remarkable.

His parents being poor, it was necessary for him to rely upon his own energy for his advancement. This he did, and worked with a vim and enthusiasm beyond his years. He at last finished his apprenticeship, but not content with that, he worked three months over his time, without salary, to perfect himself in some of the branches in which he thought himself to be lacking. About the time he finished these three months, he lost his mother and father, and his eldest sister was left for him to support. He felt that the knowledge of mathematics was absolutely indispensable to attaining perfection in the art, and accordingly he found means to attend a course of public lectures which were given at the College Mazarin. The professor was struck with the unwearied assiduity of his young pupil, and they became fast friends, and this friendship contributed not a little to the progress of the student. Time and perseverance conquers everything, and the young clock-maker soon became a skilful workman, and in a short time an accomplished artist. A few years only, and the name of Breguet was celebrated throughout the globe.

The revolution of 1789 destroyed the first establishment of Breguet, and the great artist was obliged to seek an asylum on a foreign shore.

After an absence of two years, however, he returned to Paris and opened a new establishment, which flourished until his death, which occurred in 1823.

The following little anecdote will serve to prove the high esteem in which this artist was held even out of France. One day a watch, to whose construction Breguet had given his entire attention, happened to fall into the hands of one Arnold. Now Arnold was a celebrated English watchmaker, and he surveyed with admiration the simplicity of its mechanism and the perfection of the workmanship. He could scarcely be persuaded that a specimen thus executed could be the work of French industry. Yielding to the love of his art, he immediately set out for Paris without any other object than simply to become acquainted with the French artist. On arriving in Paris he went immediately to see Breguet, and soon these two men were acquainted with each other. They seem indeed to have formed a mutual friendship. In order that Breguet might give Arnold the highest token of his affection and esteem, he requested him to take his son with him to be taught his profession, and this was acceded to.

Breguet was member of the Institute, was clock-maker to the navy, and member of the bureau of Longitude. He was indeed the most celebrated clock-maker of the age. He had brought to perfection every branch of his art. Nothing could surpass the delicacy and ingenuity of his free escapement with a maintaining power. To him we owe another escapement known as the "natural," in which there is no spring, and oil is not needed; but another and still more perfect one, is the double escapement, where the precision of the contacts renders the use of oil equally unnecessary, and in which the waste of power in the pendulum is repaired at each vibration.

The sea-watches or chronometers of Breguet are famous throughout the world. It is well known that these watches are every moment subject to change of position from the rolling and

pitching of the vessel. Breguet conceived the bold thought of inclosing the whole mechanism of the escapement and the spring in a circular envelope, making a complete revolution every two minutes. The inequality of position is thus, as it were, equalized in that short space of time; the mechanism itself producing compensation, whether the chronometer is subjected to any continuous movement, or kept steady in an upright or an inclined position. Breguet did still more; he found means to preserve the regularity of his chronometers even in case of their getting any sudden shock or fall, and this he did by the parachute. Sir Thomas Brisbane put one of them to proof, carrying it about with him on horseback and on long journeys and voyages. In sixteen months the greatest daily loss was only a second and a half—that is, the 57,600th part of a daily revolution.

Such is the encouraging example of Breguet, who was at first only a workman; and to this he owes his being the best judge of good workmen, as he was the best friend to them. He sought out such everywhere, even in other countries; gave them the instruction of a master of the art, and treated them with the kindness of a father. They were indebted to him for their prosperity, and he owed to them the increase of fortune and fame. He well understood the advantages of a judicious division of labor, according to the several capacities of artisans. By this means he was able to meet the demand for pieces of his workmanship not less remarkable for elegance and beauty than for extreme accuracy. It may indeed be said that Breguet's efforts gave a character to French horology that it has never lost. So much may one man do in his day and generation to give an impetus to an important branch of national industry.

AERIAL NAVIGATION.—A discovery has been made in Paris of the twelve manuscript books on aerial navigation, by Leonardo da Vinci. The screw propeller is the system on which Leonardo made his experiments, and his sections and diagrams are all clear and neat.

Art at Home.—Artistic Household Adornments at Small Cost.

A VERY handsome ornament can be made of an unglazed terra cotta vase. This ware is porous, and hence it can be easily saturated by placing the vase in a bucket of water for twenty-four hours; then remove it and scatter over the surface small seeds, completely filling the interstices, from which there will shortly appear an interesting germination, forming a "living vase" that is remarkably ornamental. When the plants are developed, to prevent them from becoming detached take pack thread or fine wire and pass a row or two around the vase; the same will soon be concealed by the increased vegetation. Should the vase selected or preferred be a non-porous ware, cover it with a piece of cloth thoroughly wet and scatter over this the seed, the growth of which will be very prolific and exceedingly novel.

A pretty piece of industry for the warm weather may be found in utilizing a yard or two of "butcher's" linen. Fringe out the edges, and for a pretty heading draw out the threads to the width of an inch, hemstitch the same with French embroidery cotton; for the centre draw with a lead pencil a wreath of scroll work and trace over the lines with cotton a chain stitching, and where the curves are sharp do them in double chain stitch which gives a pretty change producing quite an ornamental pattern. When the article is finished it can be used in several ways if spread over the centre of a dark tablecloth. Where the gaslight or lamplight is reflected on the white linen, the effect is very novel. A set of covers for a bureau and washstand can be easily made of this same style of linen. Fringe out the ends to the depth of four inches, then knot a heading by taking ten threads in a cluster and tying the same at the top; over the tie, knot a coarse thread of French embroidery cotton, clipping the ends closely; dot the sides with the same kind of thread, which must be carried to the next dot without clipping, and in this manner a pretty network is traced with-

out any difficulty. Embroider in the centre some sort of Japanese design; the pattern selected should be as quaint as can be found, and executed in blue cotton if the dots are wrought in scarlet.

A unique shopping bag is made of common bed ticking, the blue stripes covered partially with gold thread (a good sized ball is sold for 18 cents); the effect is artistic; the blue tint just visible gives a charming subdued beauty to the gold work; the white stripes are adorned with point russe; stitch in embroidery silks of bright shades spanning the stripe at short intervals. The effect is very rich, showing off splendidly the color combinations; finish the top of the bag with silk or satin and adorn the corners with silk tassels or ribbon bows. The cost of these materials will not exceed $1.50, and a bag is made that will look far more artistic than one formed of cotton macrame lace. The linen macrame lace is very handsome, and when brought in combination with handsome ribbons and good silks the results of such artistic work is exceedingly satisfactory.

A wall pocket, formed of Japanese fans is quite an addition to a prettily furnished sleeping room. Arrange the fans one above the other, taking two for the base; shorten the handles of the other three fans, which should be tacked to a strip of stiff paper, covered with satin or brocade. Around the fans run a fluting of narrow lace, and adorn the handles with very narrow ribbons, Maypole style; cross the handles of the first or lower fans, and here place a cluster of buds or a brilliant butterfly with spread wings, and tack the pocket to the wall.

Oriental embroidery is very effective on plain Swiss muslin curtains. Select quaint patterns and finish off the edge with a ruffle of the same goods laid in fine knife plaits. Another pleasing style of curtain drapery is obtained in this manner: Take unbleached muslin, (that at six cents per yard is the best), cut the same into strips about four inches wide; purchase common lace insertion, and buy half an ounce of cochineal, put this into a quart of vinegar and water, and dye the insertion a rich pink. When combined with the cloth pieces a very attractive bedroom curtain is obtained at small cost and very little labor. Cheap unbleached muslin curtains are made to look very picturesque by drawing out the threads a space of two inches on the sides and at the lower edge; hemstitch the same with French cotton and trace with embroidery cotton at regular intervals over the rest of the drapery clustered leaves, and give to the outer edge a finish of pleated lace, which may be had for five cents a yard.

A collection of specimens of plants, carefully dried and preserved in a book manufactured for this purpose, forms an exceedingly interesting industry, and also gives an excellent opportunity for acquiring a knowledge of plants that might not be obtained unless engaged in forming a hortus siccus. In order to make this style of book interesting beyond the mere sight of the plants, a brief sketch of the same should be written on the opposite leaf. Some flowers are difficult to press, and especially when about half dried, the leaves break off or the stems crumble to pieces, and thus the plant is made useless; however, with care and particular attention this trouble can be obviated. When plants are gathered they should be at once arranged and laid between the leaves of an old book or in a newspaper; if the latter, then an old book cover or stiff pasteboard is required, into which lay the paper containing the plants, and place the whole beneath a weight. Leave it there for several days, then look at the work, and turn over the plants; should the paper be much stained remove it and lay the flowers in fresh paper. When sufficiently dry place in the blank book, classing them. A narrow bit of ribbon formed into a bow and glued to the stems clustered gives a bright finish to the page. When ferns are bleached they make an interesting decoration to the pages of a hortus siccus. The bleaching is done in this manner: To three quarts of water put six ounces of liquid chloride of lime and twelve ounces of sal soda. Lay the fern leaves into a basin of clear water, adding a small portion of the preparation from time to time until the leaves are nearly white: then

remove them with a bit of blotting paper and place them on a board (covered with a towel), and let them dry gradually by not exposing them to the full rays of the sun.

Spatter work is exceedingly interesting, and when neatly executed the result is particularly pleasing. Almost every kind of leaf can be used. Some prefer ferns to all others, and every kind of small flower may be used to advantage. Press the leaves for an hour or so before using. The process of spattering is simple, and may be executed by quite small girls. Place a piece of thick paper on a smooth board, tacking the same at the corners; lay on the leaves as required that is suiting special taste, and tack them down; then go over the paper with a brush saturated with India ink, or take a very fine comb and use this instead of the brush; when the paper is dark enough remove the leaves.

Portraiture for Amateurs.

THE taking of portraits in groups —even in a well-appointed studio, where the light is under full control and the most perfect of apparatus at command—is one of the most difficult phases of portrait photography, and one that taxes the skill of the operator to its fullest extent in order to obtain satisfactory likenesses, at the same time combined with an artistic picture.

After calling attention to this fact it will be manifest that one of the principal considerations in connection with outdoor portraiture—and one upon which much necessarily depends in obtaining satisfactory pictures—is the judicious selection of a situation for our operations. On this part of the question no definite instructions can, of course, be given, as all must of necessity be dependent upon the space available. However, we shall endeavor to give the student a few practical hints which may materially assist him in his selection, and, at the same time, help him to make the best of what circumstances have placed at his command.

First, let us consider our present requirements apart from the apparatus, as that portion of the question has been fully disposed of by abler authorities. A space is required where the sitters can be posed so that the sun does not shine directly upon them, and where the surroundings will form a good natural background. This is an important matter from a pictorial point of view; for what looks worse than to see a picture, otherwise good, spoiled by an unsightly background? Yet one often sees a group of figures posed before a plain, flat brick wall; and nothing uglier than this, in the eyes of an artist, can well be imagined as a background.

One thing to be specially guarded against, when it can possibly be avoided, is to include any portion of the sky in the picture, except, perhaps, when taking sunlit pictures. We also require sufficient space to allow of the camera being placed at such a distance from the group that the whole of the figures are included on the size of plate with which we are working. Furthermore, it is very desirable that the situation chosen be one in which the sun does not shine upon the lens; for, although the direct rays may be shielded from it during exposure, it will not be possible to obtain anything like so brilliant a negative as if it were shining in any other direction. If a veranda be available, it will, as a rule, form a very desirable spot for operations, as the main building with which it is connected will block out the sky, as well as tend to shield the lens from extraneous light. It will also afford us facilities for obtaining good *chiaroscuro*, as, generally, the supporting columns are covered with trailing plants of some kind, whose foliage casts shadows which may be utilized with advantage in the composition.

In posing a group under or about a veranda, care must be exercised that none of the figures are placed in deep shadow while others are in strong light, otherwise in the picture some of the faces will be dark—sometimes nearly black, while others are all that can be desired. This is very likely to occur if the roof be a low one and some of the figures are standing beneath it. When any of the figures are

arranged under a low veranda they should be sitting, or, if standing, brought well forward, so that the shadow cast from the roof or foliage does not fall upon any of the faces. This arrangement, if the central figures be under the veranda, will suit the requirements of the lenses admirably. When very fair and very dark persons have to be included in the same picture, the blondes may with advantage be posed somewhat under cover, whilst the brunettes are brought more into the open.

In composing the group, the figures should be arranged as much as possible in the middle of the plate, the principal figures occupying the most central position, as the centre should always be the most important part of the picture. A few plants or shrubs in pots, judiciously distributed, will form charming acccessories when the group is posed in the vicinity of a veranda. Some of the most successful outdoor groups we have ever seen were taken under or about a veranda that was charmingly covered with creeping plants.

A portico or porch affords a very admirable situation for posing a group, particularly when only a few figures have to be included, as some one or two may be arranged within and the others outside, taking care, as in the case of the veranda, that those which are posed within are in no way placed in direct shadow. This is best avoided by having those within seated and fairly well forward, so that they will be clear of the cast shadows from the roof and sides. Porticos are usually covered with foliage of one description or other, which is a great advantage for our present purpose. When the foliage happens to be ivy (which it frequently is) a very full exposure must always be given to the negative, otherwise the background will be exceedingly dark in the resulting picture, the foliage of ivy being of such a very non-actinic character; and, unless the sun be shining directly upon it so as to produce bright reflections from the leaves, it will always look unpleasantly heavy unless very fully exposed.

Very admirable groups may be secured with an open window as a background. Some of the figures may then be arranged within the room, while others are without on either side. If the window be a French window, opening to the ground, so much the better, as then the whole of the figures of those inside the room, whether standing or sitting, can be included in the composition. It is necessary, in arranging a group thus, to be careful that none of those figures which are outside shall be in such a position as to cast a shadow, at least, on the faces of those within. This arrangement, it will be seen, favors the lens, as the centre figures are situated at a greater distance from it than those at the sides.

When some of the sitters happen to be in very light dresses, it is always advisable to pose them in such a manner that the dress, or the major portion of it, is hidden or subdued. This is easily accomplished with the window background, by placing such sitters inside the room, or, in the case of either of the other situations, by arranging those in the light dresses somewhat behind the others, so that the dress is, for the most part, hidden by those in front, or a strong shadow from them is cast upon it.

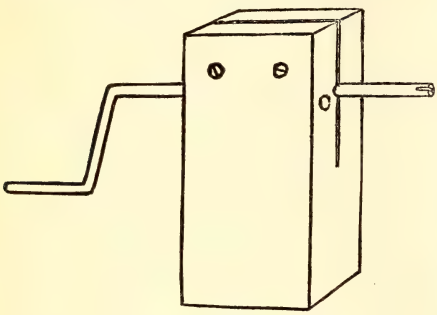
In taking a photograph where a window forms part of the background, care must be observed that no reflections from the glass is shown in it, otherwise it will cause the picture to look patchy. These reflections should be carefully looked for when focussing, and, if any be noticed, they can generally be avoided by slightly altering the position of the camera—placing it at a slightly different angle with regard to the reflecting surface.

In concluding this article, we cannot too strongly impress upon the student the necessity of observing, when the group is finally arranged, that all the faces are equally illumined, otherwise it will be impossible to secure equal density in the negative, which, if successful portraits be the chief consideration, is most essential.

— Out of all the myriad lights in the heavens, the Earth is visible only to the Moon, Mercury, Mars, and Venus.

A Tool for Winding Coiled Springs.

A CONVENIENT tool for winding coiled springs may be made as shown in the accompanying illustration. Procure a block of hard wood of any convenient size, say about four inches wide, about two inches thick and about eight inches long. Bore a hole through it near the upper end to



receive the cranked rod as shown. This rod may be of the size that the spring is to be made, or a little less in size, as the spring will open some after being wound. Saw a slot down through the centre of the block and the centre of the hole bored to receive the rod. Let this slot extend about half the length of the block. At the upper end put in two common wood screws, that do not quite reach through the wood. These screws, when turned in, will serve to keep the rod steady, especially if it be a little smaller than the hole; or, if one rod is of little less diameter than another. One end of the rod is bent in form of a crank as a means of turning it, and the other end has a small slot made in it to receive the end of the wire, and so hold it when beginning to form the coil. A small staple is driven into the block through which to pass the wire. To coil a spring, draw the rod back so that only the slotted end projects, pass the wire through the staple, and insert the end in the slot of the rod. Now turn steadily, and as the wire is wound it will draw the rod endwise through the block. This will form a close wound and even spring.

To make an open spring, two wires can be wound side by side, and the opening will be of the diameter of the wire. To make a greater or less opening, hold a hooked piece of iron on the rod, and let this come between the wire as it is wound on the rod. Its width will determine the opening of the coil.

To have larger or smaller springs, wire of greater or less size must be used, and different sized holes to receive these rods may be made in the same block. The length of the rod will govern the length of the spring, although when wound as long as the rod will permit, the spring can be pushed off, and the lost turn caught in the slot at the end of the rod, and another length made.

The block can be held in a vise, or it can be held to a bench or plank by means of screws put through the lower end.

Strange Weapons, and Stranger Ways of Using Them.

FROM the stick, stone, or club carried by many a savage hunter to the intricate and carefully-finished piece of mechanism which forms the equipment of the sportsman of civilized countries, is a very long stride, but between these two extremes are to be found a number of weapons and devices for capturing and destroying the various wild animals—or even man himself—which, as the invention frequently of beings who occupy a very low position in the human scale, cannot but raise a feeling of admiration and astonishment. It is of some of these I purpose to speak in the present article.

We will commence by a description of the hunting of horses by means of that terrible weapon of Central America, the lasso. Without the lasso, the Mexican owner of large herds of half-wild horses would find it utterly beyond his power to capture the members of his flock, either for the purposes of sale or of ridding them of the numerous insect pests which in many cases would make short work of the unfortunate animals whom they persecute with their attentions.

Let us see how the *vaquero* goes to work. Armed with his lasso—which is composed of three strips of raw leather, plaited, and is about forty feet in length—and mounted on a powerful horse, he follows the animal he has selected until he finds himself within a proper distance for throwing his weapon with the best effect. Seizing the iron ring which is attached to one end of the lasso with his left hand, he draws the lasso through it with his right, and, stretching out his arms so as

to make a noose of some six feet in length, he grasps the ring with his right hand, whirls the noose several times round his head and hurls it with unerring aim, seldom failing in placing it around the horse's neck. The noose immediately runs up tight, when a dexterous twist causes a coil of the lasso to encircle its nose, and the interruption of the respiration which ensues brings the horse to a dead halt. The *vaquero* then springs from his steed, carefully approaches the captured animal, bandages its eyes with his handkerchief, and speedily relieves it of the pests which would otherwise literally devour it.

Somewhat akin to the lasso is the bolas of the Indians of the Pampas, Patagonia, and other parts of the great American continent. This formidable weapon is composed of two thongs formed of several strands of raw hide, plaited together, and measuring from four or five to nine feet in length. At one extremity of each thong is a ball of stone, iron, or copper, as the case may be, the latter being the most valuable on account of its superior weight, and therefore the smaller size which the balls may be made, and the consequent greater handiness of the weapon. When stone is used, the bolas are about as large as a cricket-ball, and are fashioned with great care by the Indian women, the grinding of one stone to a circular shape making a good hard day's work. The balls are then placed in bags of leather, which have a number of holes round their mouths, into which the thongs are plaited and interlaced, the other ends being connected together by a short piece of raw hide. The Indian twists the bolas round his body in such a way that it can be immediately detached when opportunity occurs for its use. He then, with a preliminary whirl around his head, launches it at the mark, be it man or beast, and such is the dexterity with which it is thrown, that he can either cause it to slay outright by twisting round the neck of the victim and choking him or dashing out his brains with the heavy balls, or he can content himself with simply breaking a limb or merely twining the thongs around the body and causing the balls to fall in such a way as to hamper the movements of the swiftest animal, and give the hunter time to approach and secure it.

John Chinaman's method of taking ducks is a sample of the ingenuity and wiliness which form a staple part of the character of the "heathen Chinee." John sees a flock of ducks disporting themselves on the surface of the river, and, getting above stream, cautiously launches a gourd from the bank, which is soon carried into the midst of the feathered bipeds. Of course, a vast amount of quacking immediately ensues; but presently the ducks' suspicions are overcome, and they allow the successive gourds that John sends out to make their way amongst them with less and less comment. Now is John's opportunity, and, placing over his head a gourd, which he has carefully hollowed and provided with loopholes for looking through, he wades cautiously into the stream, and presently is in the midst of the feathered convoy, the whole of his body being concealed beneath the water. The ducks see nothing suspicious in the arrival of the new gourd, and one after one they are dragged beneath the water without a sound, and fastened to the girdle of our friend, who in this way reaps a splendid harvest.

The unfortunate duck is made the victim of another fraud in swampy fens. There, on the broad sheets of water which form the distinctive feature of these districts, the trapper builds a long tunnel of wicker-work, which is bedaubed with clay, half concealed with rushes, and made to look as innocent as possible. Then he sets afloat two or three carefully-trained decoy ducks, which, getting amongst the flock of wild ones, gradually lead them to the mouth of the tunnel. In this work the decoys are assisted by dogs trained to run along the banks, and, by their barking, frighten the wild birds, and drive them in the required direction. Led by the decoys, they are only too glad to take refuge in the innocent-looking tunnel, but at the other end the hunter is waiting for them, and, once within the mouth of the deceitful haven, they have passed far towards that bourne from which no duck returns.

Here is a plan adopted by the peasants on the French side of the Pyrenees for the capture of the flocks of birds of passage which at certain periods of the year pass through the country which they inhabit, and generally for taking all kinds of birds that fly in flocks in that part of Europe. it is customary for the inhabitants of the villages to combine together to erect a number of tripods, which rise to a height superior to that of any of the trees in the neighborhood, and on the top of each is placed a hunter, provided with a sort of kite in the shape of a sparrow-hawk. At some considerable distance from the tripods are a number of nets, suspended between the trees so as to form a vertical wall of net-work, rising to a height of thirty, forty, fifty, or sixty feet and upwards. Upon the ground, in a little hut is another hunter, lying at full length, and peering through a small hole left in the front of his shelter-place. As soon as a flock of birds is descried, it is allowed to get between the line of tripods and the nets, when first one hunter and then another launches

out from him his sparrow-hawk kite, which he draws back by the cord which retains it, launching it out again and again as occasion may require. At the same time the whole body of hunters raise a chorus of the most unearthly cries. Frightened by the din, and the sparrow-hawks floating over them, the flock of birds gradually descend lower and lower, until, by skilful manœuvring, they are made to alight just beneath the vertical nets. Now is the time for the gentleman in the shelter-hut. He lets go the cords which retain the nets in position, the nets fall forward upon the frightened birds, and, *voila tout!*

Of pigmy stature, and of perhaps the lowest grade of any of the races of humanity, possessing neither headmen nor chiefs, nor even proper names, the miserable Bushman or Bosjesman of South Africa is yet dreaded and avoided by the stalwart and warlike Kaffirs, Zulus, and Hottentots by whom he is surrounded. So much is this the case that these tribes submit in quietness to the loss of the greater part of their worldly goods in the shape of cattle and horses, which are constantly being stolen by their crafty little enemy, who can hide himself behind a stone or a few shreds of scanty herbage, or, if necessary, bury his yellow body in the sand, which in color it so nearly resembles, in order that he may escape detection and carry out his nefarious designs. Indeed, it is not until their patience is utterly exhausted by the numerous depredations to which they are subjected that a number of them will reluctantly combine together to root out their wily foes. And why is this ? No one who looks at that puny savage carrying a tiny little bow and a quiver of wretched, featherless arrows, never exceeding eighteen inches in length, and of about the thickness of a quill, the heads frequently composed of pieces of bone, and only occasionally of small triangular-shaped bits of that to him almost priceless metal—iron, would imagine that he possessed much power to harm any living being, much less the magnificent natives of the Cape and the adjacent country. But these same wretched little arrows are tipped with a subtle poison, which in almost all cases carries death with a scratch, and in some cases, according to the kind of poison used, causes the victim excruciating torture, speedily ending in the loss of reason and death. The little weapon is manufactured first of a reed, bound at one end by a piece of ligament from an ostrich, or some other animal; on the other end is placed a piece of bone, to give weight at the tip, and assist the arrow in its flight; and next comes the sharp triangle of bone or iron which is to form the barb, and which is placed loosely in its socket, so that when it has struck the mark the shaft of the arrow may be withdrawn, but the head will remain within the wound. Three kinds of poison are used, the first entirely vegetable, the next vegetable with which is mixed virus extracted from the poison-bag of the cobra, or some other venomous serpent, and the third consisting of the juice of a grub called n'gwa or k'aa, which latter kind causes the indescribable agony already referred to. It is a disputed point whether or not any antidote exists with regard to the first and third of these poisons, but in respect of the second the mixed nature of the venom renders the application of any remedy out of the question. Fortunately for his neighbors, the Bushman is but an indifferent marksman, and unless he can get within six or seven yards of his target anything smaller than a haystack is pretty certain to escape unhurt. The Bushman carries several of his arrows in his headdress. This is his invariable practice, so that he may always have some ready to hand, and such is the rapidity with which he can snatch them from their place and fit them to his bow that it is no uncommon feat for a Bushman to get off three shots within two seconds.

Now we come to what is perhaps the most remarkable of all weapons. Certainly it is the only one that possesses the power of returning to the hand of its owner after it has been thrown, providing always it has failed to hit the mark, and its flight has not been affected by coming into contact with any object. An Australian native is not overburdened with goods and chattels, and usually carries the whole of his worldly property with him. This consists of his loin cloth, with a cord spun from the fur of the opossum round his waist, in which is stuck at the back, his hatchet, the head of which comes exactly over and in a line with his spine. In the same cord, which is very elastic, are placed his boomerang, or kiley, and his dow-uk, a short heavy stick for flinging at the smaller animals. In his left hand he carries his throwing-stick and several spears, headed in two or three different ways, to answer the various requirements of war or of hunting. See him when engaged in the chase of the cockatoo, as he crawls noiselessly towards the edge of some broad lagoon, yet not so noiselessly but he rouses the suspicion of the sentinel cockatoos, who draw in to the main body of the flock, which is asleep on the branches of the trees which cover the banks. Presently the Australian springs to his feet as the birds take the alarm and circle in dense masses above the still water. Raising his right hand over the shoulder, he takes

one or two steps forward, and away flies the boomerang straight before him, but gradually nearing the surface of the lake, when just as it appears about to bury itself in the dark water, up it soars with inconceivable velocity into the midst of the startled cockatoos, striking right and left upwards and downwards, its wild gyrations rendered still more extravagant by the resistance of the birds which fall victims to its blows.

Another very remarkable weapon is that in use amongst several of the tribes of Guiana, notably the Macoushie Indians, who have the reputation of being the best makers of it. The wonderful blowpipe which varies in length from nine to eleven feet, and is formed out of a reed, which must be absolutely devoid of anything approaching the semblance of a knot, and the bore of which must not diminish appreciably throughout its entire length. Let the studious reader imagine what the complete reed must be like which fulfils these requirements. It is estimated that it must be at least 200 feet in length, and is probably an aquatic plant, the weight of which is supported by the water. Slender as the tube is, it would readily be broken were it not protected by an outer case, formed of the stem of a young palm-tree, from which the pith has been extracted, and in the centre of which the reed is cemented with kurumanni-wax with mathematical accuracy. A foresight with a dent in it similar to the backsight of the modern rifle is formed from a seed of the acuero, and the two upper incisor teeth of a small rodent called the acouchi, provide the backsight, which again bears some resemblance to the foresight of our best rifles. The projectile, which is made from the leaf ribs of a palm, is about nine inches in length, of the thickness of a knitting-needle, and is sharpened to the utmost degree. A pad of cotton is fastened at the feather end of this tiny arrow, which exactly fits the bore of the blow-tube. But the instrument is not yet complete. There remains to dip it in the deadly *wourali* poison—so deadly that should the Indian accidentally scratch himself with his venom-tipped dart, he immediately bids farewell to his friends and relatives, knowing that his hours, nay, his moments, are infallibly numbered. To provide against such a contingency he carries his darts in a peculiarly-shaped quiver, which, whilst it permits him to withdraw one arrow at a time, effectually prevents the points from coming into contact with his hand. The *moment* his quarry is struck the poison begins its work. The bird is unable even to lift its wings, and after nodding drowsily for a few moments, it falls dead at the Indian's feet. But for this rapid action of the poison the weapon would be of little avail, for in a country where vegetation is so dense, and grows with such amazing luxuriance and speed that a road which is made to-day cannot be found a fortnight hence, a flight of a very few yards would mean the almost certain loss of the animal in the tangled foliage. How the birds killed by so terrible a poison are made harmless food for man has not been explained by travellers.

Last, we come to a device which is used for the capture of that Ishmael amongst quardrupeds—the wolf. A strong stake is driven into the ground, and around it an enclosure is constructed, without any opening whatever. At the distance of from two to three feet from this is erected another enclosure, with a door in it opening inwards, and prevented from going too far back by a stout post driven into the ground. Each of the walls is of a sufficient height to prevent the wolf from leaping over it. To the stake a young lamb or kid is fastened, whose frightened bleatings soon fall like music on the ear of the ever hungry wolf. At once he makes his way to the enclosure, and, entering by the door, walks round, seeking an opening by which he can get at the young mutton so temptingly displayed a few inches beyond his very nose. Arriving at the gate which bars his further progress, he gives it a push. It fastens with a spring, and all that remains is for the hunter to quietly walk in, bind the wolf's jaws and legs, and congratulate himself on capturing one more despoiler of his flock. The securing of the wolf after he is in the enclosure is a task of no difficulty, for although he will fight to the death in the open, when he is cornered his courage entirely leaves him, and he may be bound without offering the least resistance.

Amateur Theatricals.

AS a hint, or series of hints to some of our readers who "indulge" in amateur theatrical exhibitions, we give the following experience which was obtained from before and behind the scenes:

"Passing through the folds of a remnant of old sailcloth I find myself in the corner of a large loft—partly covering a row of stables—stables unmistakably, from the occasional clamps of tired horses and the fragrant odor which proceeds therefrom—a little below the level of the foot-lights, and on the far side of the stage. There are no reserved seats whatever. From the raised platform to the outer walls are a number of rough planks ranged longitudinally, rising one above another as in an ordinary gallery. In the topmost corner on the right hand

is a small inclosure with a counter, devoted to the sale of "oranges, apples, and lemonade." The arrangements behind the curtain are primitive and simple; there are four tolerably well-painted scenes slung upon rollers, comprising an exterior, an interior, a wood, and a street. The brick-work at the back of the stage is colored to represent a landscape. Wings there are none; but the proscenium—three feet wide on each side—being fixed parallel with the seats, offers some slight protection to the actors in their entrances and exits. The musical element was sparsely represented; one instrument only—a violin—(an organ would have answered just as well) constituted the entire orchestra. Gas, of course, was unvailable, and candles were too insignificant; the boys, therefore, resorted to the use of a fearful compound of grease and oil, the fumes of which were suffocating. Five pans, in shape like huge garden saucers, were filled with this precious liquid and placed at intervals along the edge of the platform to do duty as "floats." Sometimes the business of the drama required a night effect; this was managed by means of a long slip of board fastened to the stage by hinges, but lying flat thereon, until the appearance of the blood-stained spectre or the pallid ghost called for darkness, when, by the aid of a cord attached to each end, it was raised, and the necessary result followed. It should be mentioned that there are three "houses" or performances nightly, each of which lasts about an hour. The reader is supposed to be present at the first of these, say at 7 o'clock. By this time the audience has increased in number, and of course, to be like boys, they must make a noise that is deafening. "Stop it, old scraper" or "Rosin your Bow." "Pull up the rag!" "Now, then, look alive!" etc. Before the curtain rises, however, it may be as well to mention a little peculiarity attaching to the dramas enacted here. To-night we are to have "The Highland Cateran;" to-morrow, perhaps, "The Outlaw," and the night following, "The Freebooter." Thus with variations—harping on the same old string—we at last arrive at "Rob Roy" which generally ends the series of performances."

— We cannot tell how much we love by how much we feel. The matter of feeling is purely a matter of a little more or a less nerve put into the fibre—a little more or a little less sensibility. There is no moral quality in the basic element which constitutes a test. The strength and depth and purity of love is the heroic test. How much will your bear? How much will you suffer? How much will you sacrifice.

Our Girl's Department.

This department is intended exclusively for "Our Girls," and we hope to make it both interesting and instructive, and to this end we ask our young lady readers to assist by contributions, suggestions, or illustrations. There are thousands of little things that can be, and have been, made and done by young ladies, pertaining to decorative art, needle-work, etc., etc., that would be gladly followed but for a want of knowledge on the subject, and we know of no more pleasing task for a lady than that of teaching her younger sisters that which they are anxious to learn, and which may prove of real benefit to them in the future, as well as being useful and interesting for the present. We trust we will have no difficulty in persuading those who have something nice to show or speak of, to make use of this department. Remember, it is open to all, and if you have anything worth knowing suitable for this column, send it along, and we will give it our best attention. Do not be afraid to write because you may fancy your composition is not perfect, or have other scruples of a similar kind. Do the best you can, and leave the rest to the editor of this department, and we are sure you will be pleased with your work.

IF anything affects your eye, you hasten to have it removed; but if your mind is disordered you postpone the term of cure for a year.—*Horace.*

— Comparison, more than reality, makes men happy, and can make them wretched.—*Feltham.*

— To what atrocities cannot that mind reach which is impelled by selfish avarice.—*Virgil.*

— Let friendship creep gently to a height; if it rush to it, it may soon run itself out of breath.—*Fuller.*

— Many are ambitious of saying grand things—that is, of being grandiloquent. Eloquence is speaking out, a quality few esteem and fewer aim at.—*Hare.*

— Religion gives part of its reward in hand, the present comfort of having done our duty; and for the rest, it offers us the best security that Heaven can give.—*Tillotson.*

— The lightsome countenance of a friend giveth such an inward decking to the house where it lodgeth, as proudest palaces have cause to envy the gilding.—*Sir Philip Sidney.*

— There is a thread in our thoughts as there is a pulse in our feelings—he who

can hold the one knows how to think, and he who can move the other knows how to feel.

— Open rebukes are for magistrates and courts of justice. Private rebukes are for friends, where all the witnesses of the offender's blushes are blind and deaf and dumb.—*Feltham.*

— People may make injuries worse by unreasonable conduct, by giving way to anger and satisfying that for the moment, instead of thinking what will be the effect in the future.—*George Eliot.*

— A good memory is the best monument. Others are subject to casualty or time, and we know that the pyramids themselves, rotting with age, have forgotten the names of their founders.—*Fuller.*

— To divert at any time a troublesome fancy, run to thy books. They presently fix thee to them, and drive the other out of thy thoughts. They always receive thee with the same kindness.—*Thomas Fuller.*

— What we call miracles and wonders of art are not so to Him who created them; for they were created by the natural movement of His own great soul. Statues, paintings, churches, poems, are but shadows of Himself.—*Longfellow.*

— I always fancy I can hear the wheels clicking in a calculator's brain. The power of dealing with numbers is a kind of "detached lever" arrangement, which may be put into a mighty poor watch.—*Holmes.*

— Socrates called beauty a short-lived tyranny; Plato, a privilege of nature; Theophrastus, a silent cheat; Theocritus, a delightful prejudice; Carneades, a solitary kingdom; Domitian said that nothing was more grateful; Aristotle affirmed that beauty was better than all the letters of recommendation in the world; Homer, that it was a glorious gift of nature; and Ovid, alluding to him, calls it a favor bestowed by the gods.—*From the Italian.*

— Very many ladies have a habit while traveling of gathering leaves, sprays, or single blossoms, small reminiscences of pleasant journeys, etc., and pressing them in a sketch-book or small portfolio, previous to their being taken home and prettily arranged in the long winter evenings, when they awaken pleasant or sad remembrances, as the case may be, of days long past. The dried flowers, leaves, grasses, moss, etc., should be arranged on pieces of cardboard cut the same size, either in different groups of flowers, or like a graceful frame around a small sketch, with a quotation from a favorite poet below, in this case the single flowers must be gummed on with rather a thick liquid gum, which of course requires great care. If kept in a case on purpose, the collection will soon form a pretty album.

In passin' thro' this warld o' cares,
  Hoo aften dae we feel
Sad an' forlorn 'neath Fortune's scorn;
  E'en Reason seems to reel.
Yet we su'd ever bear in mind
  That He wha dis nae wrang,
Has made a law that ane an' a
  Maun creep afore they gang.
    Sae creep afore ye gang.
    Jist creep afore ye gang.
An' dinna let yer heid hing doun
  Tho' griefs the bosom thrang;
For bit by bit ye'll yet come roun',
  Then creep afore ye gang.

We've a' oor sorrows mair or less
  Oor lifetime tae endure,
But oh, how hard it is for some
  A leevin' tae secure;
Yet mony rise tae eminence
  Who sat in sorrow lang,
An' sae may we, gin we've the sense
  Tae creep afore we gang.
    Sae creep afore ye gang,
    Jist creep afore ye gang,
Ye canna thraw what's been decreed
  E'er man tae being sprang;
An' will be till the end indeed,
  Tae creep afore ye gang.

—*John Adam.*

— Pocket-handkerchief flirting has gone entirely out of the fashion, at least so say the girls. Parasol flirtation is the latest accomplishment in the art. The covered and figured heads are symbolic,

a plain crook meaning honesty of intention, a swan's head coyness, a crutch sympathetic, a hound devotion, and so on. The parasol carried plump overhead means keep away, as it is necessary to look about. Slightly on one side flashes the intelligence that the approach must be deferred. Thrown over the back conveys the intimation that the coast is clear. Carried way forward intimates that discretion must be exercised. Swinging round in the hand is a danger signal, meaning go away as quickly as possible. Held close down over the head means secresy. There is no significance in color, as this, if not a matter of taste, is regulated by the dress.

— A lively old lady who died far advanced in her eighties, and was proud in extreme old age of her beautiful dark hair, was accustomed, when a girl, to hang up her night-cap every morning filled with salt. This was shaken up into a japanned dressing box every night on retiring, but enough salt remained clinging to the cambric to secure, as she thought, the remarkable preservation of her hair. Dr. Holmes has sung or gossiped about the "widening part," which is one of the tell-tale tracks of passing years; but until lately the prevailing fashions of dressing the hair did not make any parting to show. Those who wear the hair in true classic style, with the pure white line from brow to crown, may find some use in the following recommendation of the New York *Evening Post* for strengthening the hair and renewing thin spots: "To a quart of warm water allow one tablespoonful of salt, and just before retiring for the night wet the head thoroughly with this, not along the widening seam alone, but the entire head. Repeat this operation for one or two nights each week until good effects are apparent." It is likely that the vigorous rubbing which this treatment makes necessary afterward is of as much use to the hair as the saline treatment.

— "Women," said a successful woman jeweller, "can do anything and everything nowadays. When I first had to earn my living I thought myself fortunate when I secured a place behind a milliner's counter. Well, I sold bonnets for a year, and the store was closed. Then I painted furniture, if you will believe it. It wasn't hard to learn, and I earned twelve dollars a week instead of seven. But I soon quit that for better employment, and was hired in a jewelry establishment. There I learned the trade, and I am as independent as you are." Miss Dora Kinney, of Wild Cat, Ind., is the boss shepherdess of the Wabash. A few years ago an uncle gave her an orphaned lamb to raise, by hand, which she did successfully, and becoming so much interested in sheep husbandry, she procured a mate for the lamb, and she now sports a fold of twenty-eight old sheep and thirty-three lambs—sixty-one in all, all from the first starting pair. Miss Kinney attends to her flocks altogether herself, both winter and summer, and now receives quite a handsome little income from the annual sales of wool and mutton. New occupations for women are yearly springing into being. The latest things I've heard of are landscape gardening, bird-fanciers, architects, junk-dealers, and pawn-brokers. Women do all these things now. Indeed, I'm afraid a bad time is coming. Women do so many kinds of work that the men will all become dudes. The fine, idle creatures these days certainly are not women.

BEAUTY.—II.

Diana of Poictiers, Duchess of Valentinois, was the reigning beauty at the courts of three successive kings of France. The historian Brautome says, "I saw this noble dame when she was about seventy years of age, and she was as charming, as fresh, and as lovely as any lady of thirty. Her beauty, grace and majesty were such as she had ever possessed. It was said that certain skilled doctors prepared for her daily a potion of soluble gold, and that this, or some valuable drug, preserved her beauty." It was not soluble gold, or valuable drugs, but a daily bath in rain water.

Mary Stuart and Margaret of Anjou, in

early times, were as wise as serpents in the magic of the toilet, disdaining neither May dew or other simple beautifiers.

Sea bathing is now so fashionable in summer, that it must be spoken of in a cosmetic point of view. It is an admirable tonic to the general system, and increases the circulation to a marked degree. Thus it often improves the looks. But as an author of reputation remarks, "As an agent for preserving the softness and delicacy of the healthy skin, and the bright hues of the complexion, it is inferior to the tepid bath." Those who live by the sea are often robust and comely, but rarely have fine skins.

The noble dames of ancient Rome, who have never been surpassed in luxury, were wont to plaster their faces at night with a poultice of bread crumbs and asses milk, which, on being removed in the morning, left a freshness and whiteness very much prized in their day. They also bathed in fresh milk, which was rather an expensive luxury.

Erasmus Wilson is said to have been the first to propose sulphur lotions for eruptions of the skin. The usual lotion of the flowers of sulphur, with glycerine water, is a valuable remedy, but from the readiness with which the sulphur separates, is inconvenient, and is not quite satisfactory in its results. A far more efficacious mode of using sulphur, is to dust it on the face every night with an ordinary puff used for toilet purposes; recently, however, cases of acne of two years' standing, which had resisted the ordinary methods of treatment, yielded at once to sulphur thus applied. If the sulphur be scented with oil of lemon or roses, it will form an elegant cosmetic. Sunburn is a redness which remains on the skin after exposure to great heat. The skin sometimes peels off, and the surface is hot, inflamed, and tender. It may be produced by the sun, or by sitting too near a hot fire. Those who cherish a delicate complexion should never sit too near the fire. When the sunburn is only occasional, it can readily be removed by the following formula. It may be applied at night after washing the skin, and be allowed to remain till morning. It not only lessens the redness, but soothes and allays the burning, dry, and irritated feeling: Spermaceti, 2 ounces; oil of almond, 2 ounces; honey, one teaspoonful. Melt the spermaceti, then add the oil of almonds; when they are thoroughly mixed stir in the honey. Take the mixture off the fire, and stir until cold. Some persons burn red much easier than others, and it is popularly regarded as a sign of health. The same difference in individuals is observable in tan. This is a brown discoloration rapidly produced on some skins by the solar rays. Here, as elsewhere, the dark hue is owing to a minute layer of carbon, which is deposited on the under surface of the skin. There are many recipes for removing tan. Washing the skin in buttermilk is a domestic suggestion. Lemon juice is also good. The solutions of corrosive sublimate, and other poisonous drugs, used by some ladies, are altogther too dangerous, and should be only prescribed by a physician. Many a fine skin is spoiled by freckles. Some have them only in the spring of the year. The exposure to the winds of March and its vernal sun, bringing them out in full force. Others have them all the year. Nearly all the means proposed in books are powerful caustics, which destroy the scarf-skin. A simple, harmless, and generally successful wash, is a saturated solution of borax in rose-water. It should be applied five or six times a day, and allowed to dry upon the skin. The following is considered good, and can be readily made: Best English mustard, a tablespoonful; oil of almonds, a teaspoonful; lemon juice enough to make a paste. Mix them well and apply, spread in a thick plaster, night and morning, until the skin smarts. After a few days, the scarf-skin will, or should loosen, and the freckles disappear. After they have gone the surface should be washed with borax and water several times a day. A delicate and effective preparation for rough skins, eruptive diseases, cuts, or ulcers is a mixture of one ounce of glycerine, half an ounce of rosemary-water, and twenty drops of carbolic acid. It is excellent for hives or prickly heat, quickly giving relief. The

carbolic acid neutralizes the poison of the blood, purifies and disinfects the eruption, and heals it rapidly.

The brown spots called moles are usually brought with us from birth. In former ages, when on the face, they could readily be concealed by patches, or what are sometimes called "beauty spots;" but those patches not being in vogue now, they must go unadorned or be removed. Dr. L. Thomas, in the British Medical Record, advises the use of "acid nitrate of mercury" for the removal of moles from the face. No pain attends the application, if care be taken to prevent touching the surrounding skin. The growth gradually shrivels away. The slough falls off in about a week, leaving a faint depression like a small-pox mark. The following is a recipe for a wash for the same purpose: Dried tops of rosemary, 4 ounces; dried leaves of sage, 4 ounces; dried flowers of lavender, 4 ounces; cloves, ½ ounce; Camphor, 1-16 ounce; distilled vinegar, 6 pints. Macerate fourteen days with heat, filter and bottle. Apply a drop twice a day to the moles, until they disappear. You can, of course, make a half or quarter of this quantity.

There is a black and greasy compound used by hunters and others who live much in the woods. It is generally used by them to keep black flies and mosquitoes away; but it has greater efficacy in whitening, softening, and refining the skin. It is also excellent for driving wrinkles away that come before their time. It is composed of tar and olive oil. Mix one spoonful of the best tar in a pint of pure olive oil; heat the two in a tin cup set in boiling water; stir until completely smooth. Rub this on the face when going to bed, and lay patches of soft cotton or linen on the cheeks and forehead to keep the tar from rubbing off. I might have been more concise and said, transform yourself into an amateur negro minstrel every night and go to bed.

A wash much used by the Spanish ladies to give firmness to a loose skin, and preventing wrinkles, is made with the whites of four eggs boiled in rose-water, to which is added half an ounce of alum and a little oil of sweet almonds. The whole beaten to a paste.

Milk of roses, or tincture of benzoin (the recipe I have given in a former number) was much used by the ladies during the time of Charles the II. for obliterating wrinkles. It is still used with success by many ladies of our day.

A little jar or glass of oatmeal is often seen on the dressing table of young girls. The meal is used in the place of soap. It contains a small amount of oil, and the friction against the skin brings the blood to the surface.

There are many washes and enamels for destroying and banishing wrinkles, but I think wrinkles are preferable to them, as they give the face a very artificial appearance, suggesting to the observer common rouge and chalk, or flour. Lady Paget says, with truth, "If women would only allow common sense to govern them, they would feel that for the inch or two they diminish the circumference of their waists by tight lacing, they become unattractive in many other ways; quite leaving on one side the hygienic part of the question, which, alas! the vain and foolish will never consider." There are few, indeed, who, like the clever and beautiful Marechale de Saubise, Louis XIV.'s faithful friend, will make the sacrifice of giving up all meat except chicken, and never wearing their stays for fear of injuring their health or complexion. Another absurd practice is that of wearing the skirts so tight and heavy that walking becomes an agony; there is no doubt that many have been debarred from healthful exercise for years. Much harm has also been done by the profuse use of perfumes, of which musk, patchouli, jessamine, and such like form the basis. These ingredients are depressing to the nervous system, acting upon it as poisons, just as they would if given inwardly, and at the right time, prove the most powerful medicines. The suggestion of the perfumer's shop is a poetic one, and the faintest suspicion of violets, lavender, or

> "The new mown hay
> Gives a sweet and wholesome odor,"

sufficient for the purposes of the toilet.

THE INDUSTRIAL PUBLICATION CO.,
294 Broadway, New York.

It is sometimes quite easy to appear good natured, but it is no test of amiability to appear good natured in the few and rare moments of serenity when all human troubles seem to have subsided. It is the boy and girl, who, when troubled, can preserve a calm and cheerful exterior to cheer those around them, who when oppressed by cares, have encouraging words for those around them, who, when disappointed or crossed themselves, have yet the disposition to point out to others the coming brightness and joy, and who give hope to others by their own cheerfulness. Such qualities as these make amiability; and the happy possessor is richer than though the mines of Golconda were his or hers.

The eleventh annual regatta of the National Association took place at Newark, N. J., on the 7th of August. The Passaic River was in fine condition for the racing, being as smooth as a piece of plate glass. The course was a mile and a half straight away, starting from the Midland bridge and ending in front of the grand stand, where a number of cylinders representing the color of the contestants were hoisted and lowered in accordance with their relative positions in the race, as telegraphed from stations set at every half mile on the course.

Some very good work was shown, the course having been traversed by junior single scullers in 8.52½, and by senior scullers in 9.00½.

In the senior four-oared shells one race was won by the Eureka Club, of Newark, N. J., in 8.06½. This showing speaks well for the rowing abilities of our amateur boatmen.

The spring and half of the midsummer cricket season of the metropolis have passed, and the record of the game compared with those of previous years shows that a larger number of clubs have played than ever before, and that there has been a great increase of cricketers in this section. The season was opened on May 14th by the Manhattans, on their grounds at Prospect Park, with a match with the Patersonians, and again, as in late years, the former club has outranked all its brother organizations in the number of games played. Second on the list as match players come the Staten Islanders, they being by far the strongest and most successful exponents of the game outside of Philadelphia. Then in order the Brooklyn, New York, St. George's, and Newark clubs have been seen in the fields.

We are pleased to notice the increased interest taken in the game of cricket, and that improved play has made a decided advance in both batting and bowling, noticeably the former, but as a rule fielding seems to be the stumbling block in all the different grades of matches. At times it is sharp and even brilliant, but then again it is almost sure to deteriorate into first prize "muffing." The attendance at the most prominent games has also been much larger than during last year, and this is especially the case when Philadelphia's crack elevens honor New York or other cities with visits, which, unfortunately, are seldom and far between. Now, as such matches are always certain of drawing a large assemblage, it seems strange that the secretaries of the clubs have not ere this arranged to play a series of games each year between

teams representing New York and Philadelphia and interstate matches during the month of September. Before the war it was a common thing to see the States of New York and Massachusetts, or New Jersey and Pennsylvania measuring bats, and a series of interstate contests at this particular time would do more to popularize cricket than any other series of games that could be thought of.

When boys—or girls either, for that matter—undertake to make or do anything that requires skill or thought, they should "make haste slowly," by doing it systematically, coolly, and deliberately. If amateur work is undertaken methodically, and free from excitement or undue eagerness, it is surprising how much more may be done, and how much better done it is. And then there is no unnecessary wear and tear of strength, no lost effort, and everything is more likely to go along smoothly. While at work, all the faculties should be concentrated upon it, for it is impossible to do good work while the hands are performing one service and the mind another. It was a shrewd observation of Kirke White, the gifted poet, whose early death adds a touch of melancholy to all he wrote, that he found, if he concentrated his whole attention on the dryest book he had to study, it soon became interesting, and in a short time he would become so absorbed as to turn over page after page unconsciously to himself. Intensity of thought is not exhausting if not too long continued; so that in one sense he who works the hardest accomplishes his task more easily. He has also much more time for rest and recreation. When at work, there should be as little interruption as possible, as these are apt to divert the mind into channels not related to the work in hand. Whatever may be the character of the work in hand—scientific, artistic, or mechanical—the surroundings should be as cheerful as possible, and with these conditions, if the worker is self-possessed and cheerful by nature, the work, no matter how hard it may be, will appear to be easy and pleasant.

Our Book Table.

A Dictionary of Useful Animals and their Products. A Manual of Ready Reference for all those which are Commercially Important, and others which man has utilized, including also a Glossary of Trade and Technical Terms connected therewith. By P. L. Simmonds. E. & F. N. Spon, Publishers. New York and London.

To students, and those interested commercially in fabrics, and other goods made from animal products, this little book will prove very useful, as it contains a great deal of information relative to these matters. Being a dictionary, the subjects are alphabetically arranged, and are easily found. So that the reader may have an idea of the work, we quote an item or two:

"Bear (*Ursus*), a well-known animal, of which there are several species. It is hunted chiefly for its skin, which is used for sleigh robes and wrappers, saddle housings and rugs. From 8,000 to 10,000 are received annually in England, but in the early part of this century nearly three times that number were imported. The flesh of nearly all bears is edible, but some is not very palatable. The long claws of the grisly bear are strung as necklaces, and highly prized as trophies of prowess among the Indian braves, who pride themselves excessively upon the number of bears they have succeeded in destroying."

"Moonga, or Mooga Silkworm (*Antherœa assama*, Helfer). The cocoons are soft and of a light fawn color. They furnish an excellent raw silk, of which there is a large consumption in British India. This silk forms one of the principal exports of Assam, and leaves the country generally in the shape of thread."

The book is well printed, and neatly and strongly bound.

Practical Carpentry. Being a guide to the correct working and laying out of all kinds of Carpenters' and Joiners' work. With the solutions of the various problems in Hip-Roofs, Gothic Work, Centering, Splayed Work, Joints and Jointing, Hinging, Dovetailing, Mitering, Timber Splicing, Hopper Work, Skylights, Raking Mouldings, Circular Work, etc., to which is prefixed a thorough treatise on "Carpenter's Geometry." By the author of "The Steel Square and Its Uses," "The Builder's Guide and Estimator's Price Book," "The Slide Rule and How to Use It," etc., etc.

This is the most complete book of the kind ever published. It is thorough, practical and reliable, and at the same time is written in a style so plain that any workman or apprentice can easily understand it, and for those of our readers who are fond of working in wood, it offers many hints and suggestions of a kind that every successful amateur *must* know. The work is published by the Industrial Publication Co., 294 Broadway, New York, and is sold at a price (one dollar) that places it within the reach of every one. It is illustrated by over 300 engravings, well printed on fine paper, and bound in a durable manner.

Hand Saws; Their Use, Care and Abuse. How to Select and How to File Them. By the author of "The Steel Square and Its Uses," "The Builder's Guide and Estimator's Price Book," "Practical Carpentry," etc., etc. Industrial Publication Co., 294 Broadway, New York. Price, in cloth, $1.00.

"Being a complete guide for selecting, using and filing all kinds of Hand Saws, Back Saws, Compass and Key-hole Saws, Web, Hack and Butcher's Saws; showing the Shapes, Forms, Angles, Pitches and Sizes of Saw Teeth suitable for all kinds of Saws, and for all kinds of Wood, Bone, Ivory and Metal; together with hints and suggestions on the choice of Files, Saw Sets, Filing Clamps and other matters pertaining to the care and management of all classes of hand and other small saws."

The foregoing, which is taken from the title page of the book, gives an idea of the scope of the work, and as the book is a thoroughly practical one, written by a practical man, it will be found useful and reliable for those who may have occasion to use saws of any kind. We heartily recommend this book to our amateur woodworkers.

Astronomy for Amateurs.—September.

BY BERLIN H. WRIGHT.

THE PLANETS.—SEPTEMBER, 1883.

(All Computations are for the Latitude and Meridian of New York City.)

Mercury may be seen as an evening star September 5th to 12th, being at greatest eastern elongation (26° 49′) September 11th, and brightest from the 8th to 11th. He sets as follows:

September	5th—7 14	evening.
"	8th—7 8	"
"	12th—6 59	"

He will be very close to the brilliant star *Alpha Virginis* (*Spica*), being only about two degrees west of or below that star.

Venus will scarcely be visible in September, being in conjunction with the Sun on the 20th.

Mars rises at midnight on the 10th, and on the 30th at 11.43 eve., and is moving eastward past the stars of the constellation Gemini.

Jupiter rises as follows:

September	10th—1 24	morning.
"	20th—0 54	"
"	30th—0 22	"

Inasmuch as it takes Jupiter an entire year to traverse a constellation or sign, his position will vary but slightly from month to month.

Saturn is now favorably situated for evening observation, rising as follows:

September	10th—10 1	evening.
"	20th— 9 22	"
"	30th— 8 42	"

He will be 90° west of the Sun on the 2d, and only one degree north of the Moon on the 21st, at 9 o'clock in the evening. Stationary, Sept. 22.

Uranus being in conjunction with the Sun on the 16th, will be invisible during this month and next.

SEPTEMBER METEORS.

The group radiating from near Algol, that from near Algenib, and that from the left of Cassiopeia's Chair will continue throughout September. A swift and brilliant group seems to radiate from a point about 10° north of Deneb, the bright star at the head of the Great Cross in the Swan; another from a point about 8° northeast of Capella, about the middle of the month. The earth enters a fine group about Sept. 25th, having a radiant about 10° south of Castor, in Gemini. This group is most active in October. A very swift and infrequent group visible in September and October, has its radiant about 20° east of Capella.

SITUATION OF THE PRINCIPAL CONSTELLATIONS, STARS, AND CLUSTERS, SEPT. 20TH, 1883, AT 9 P.M.

In the Zodiac, Capricornus crosses the Meridian, and to the right or west the constellations, etc., in their order are Saggittarius, the Archer, in which is the "Milkmaid's Dipper," Scorpio, the Scorpion, in which are many very conspicuous stars, and the first magnitude star Antares is setting.

North of the Ecliptic and west of the Meridian, the most conspicuous objects are quite near together and close to the Meridian, being the Great Cross in the Swan, which is almost directly overhead; to the right of it lies the Harp and Vega. And below it to the southward is Altair in the Eagle, and Job's Coffin; away in the northwest lies the Northern Crown and the great naked-eye nebula in Hercules.

Upon the east side of the Meridian the Zodiacal constellations are in their order from W. to E.; the eastern part of Capricornus, Aquarius, marked by the ⅄; Pisces, marked by the almost entire absence of stars brighter than the 5th magnitude. Aries and the Pleiades have but just cleared the horizon, and Taurus and the Hyades are just rising. The only bright star south of the Ecliptic is Fomalhaut, nearly two hours east of the Meridian and close to the horizon. Above the Ecliptic the first objects to catch the eye are the Great Square in Pegasus and Cassiopeia's Chair.

In the circumpolar district the Great Bear and Dipper are low in the north, almost touching the horizon; the wonderful cluster in Perseus and Cassiopeia's Chair to the right, and the Little Bear and Dipper and Serpent to the left of Polaris.

EPHEMERIDES OF THE PRINCIPAL STARS AND CLUSTERS, SEPT. 21ST, 1883.

	H.	M.	
Alpha Andromeda (Alpheratz) in meridian	0	3	mor.
Omicron Ceti (Mira) variable, in meridian	2	14	"
Beta Persei (Algol) variable, in meridian	3	1	"
Eta Tauri (Alcyone or Light of Pleiades) rises	8	9	eve.
Alpha Tauri (Aldebaran) rises	9	28	"
Alpha Aurigæ (Capella) "	6	56	"
Beta Orionis (Rigel) "	11	35	"
Alpha Orionis (Betelguese) rises	11	11	"
Alpha Canis Majoris (Sirius or Dog Star) rises	1	40	mor.
Alpha Canis Minoris (Procyon) rises	1	15	"
Alpha Leonis (Regulus) rises	3	18	"
Alpha Virginis (Spica) sets	6	44	eve.
Alpha Bootis (Arcturus) sets	9	20	"
Alpha Scorpionis (Antares) sets	8	40	"
Alpha Lyrae (Vega) in meridian	6	31	"
Alpha Aquillae (Altair) "	7	43	"
Alpha Cygni (Deneb) "	8	35	"
Alpha Pisces Australis (Fomalhaut) in meridian	10	48	"

Penn Yan, Yates Co., N. Y.

A New Variety of Glass.

The *Wiener Gewerbe-Zeitung* states that a chemist of Vienna has invented a new kind of glass, which contains no silex, potash, soda lime, or borax. In appearance it is equal to the common crystal, but more brilliant; it is perfectly transparent, white, and clear, and can be cut and polished. It is completely insoluble in water, and is not attacked by fluoric acid, but it can be corroded by hydrochloric acid and nitric acid. When in a state of fusion it adheres to iron, bronze, and zinc.

Curious Fact Concerning Boiling Water.

At a recent meeting of a scientific association it was related that a kettle filled with boiling water was hung in the hottest room of some Turkish baths, with the lid on. The temperature of the surrounding air was 262° Fah. After about an hour the temperature of the water was taken, and indicated, as was expected, 212°. The kettle was then rehung with the lid off. The temperature of the room was now 252°. In twenty minutes the temperature of the water had fallen to 185°; in thirty minutes to 178°; in forty-five minutes to 170°, and was evidently still falling. The manager stated that it generally fell finally to about 140°, when a point of equilibrium seemed to be established, and the water neither got hotter or cooler. Mr. Haddock supposes this loss of heat was due to rapid vaporization and conversion of the sensible heat of the water into the latent heat of steam, and as dry air is a very bad conductor of heat (one of the worst known), the heat required to convert a portion of the water into steam had to be abstracted from the remainder of the water, thus lowering its temperature. In substantiation of this explanation, we believe that if water is placed in a vessel over a large bulk of strong sulphuric acid, in the receiver of an air pump, and the air is exhausted, the rapid evaporation of one portion of the water will actually cause the rest to freeze.

Hardness of Ancient Bronzes.

Ludwig has made a number of analyses of ancient bronze implements, of great hardness, with the following results:—

	Copper.	Tin.	Nickel.	Iron.	Phosporus.
(1.)	87·25	13·08	0·38	trace.	0·250
(2.)	83·65	15·99	0·63	"	0·540
(3.)	85·05	14·38	trace	"	0·106
(4.)	88·06	11·76	"	"	0·027

Specimen No. 1 was a fragment of an axe from Maiersdorf. The metal was tenacious, and bright yellow; hardness equal to that of apatite (5). No. 2, an axe from Linburg; reddish golden-yellow; tenacious, and hardly scratched by feldspar (6). No. 3, fragment of a sword from Steier; the metal was reddish-yellow, solid and tenacious, and not easily scratched by quartz (7). No. 4, a chisel from Peschiera; deep yellow, and containing a trace of cobalt; hardness, 5. Neither zinc nor lead was found in any of the specimens, though the latter metal is invariably present in ancient British implements.

Electric Light in China.

The introduction of western improvements into China by Europeans is evidently a work beset with many difficulties. Some years ago the only railway in the country was purchased by the Government from the proprietors and promptly torn up; but now the officials themselves are laying down railroads from the mines in North China to the nearest canal. The telegraph also had to encounter a vigorous opposition from the authorities and people for many years. At present, however, the capital is connected by wire with the coast. The electric light is the latest improvement which has excited the suspicion and dislike of the mandarins. The foreign settlement at Shanghai has for some time been lighted on the Brush system, apparently much to the comfort and jubilation of the denizens of the "model settle-

ment," as the foreign part of the city is generally called. The promotors appear, however, to have reckoned without the Chinese officials. They probably thought that where gas was permitted there could be no objection to electricity. The Chinese governor of the district appears to be of a different opinion. He has addressed a letter to the senior Foreign Consul, requesting the removal of all the electric lamps. He has read, he says, in translations from European papers, that terrible accidents have arisen from electricity, and flatly refuses to permit the residents of Shanghai to be exposed to such dreadful risks. Hundreds of thousands of houses might be destroyed, millions of lives might be lost, even the walls of the city might be blown down if anything went wrong with the machines. He has stictly forbidden his own countrymen to use it, and has peremptorily ordered those who have already adopted it to discontinue it forthwith.

Useful Trees.

In setting out trees along the roadside too little regard is had to use. The trees that are only beautiful become in time too expensive luxuries, as they take up room which cannot profitably be spared. Some trees are valuable for bee forage, as soft maple, bass wood and locust. The latter is also a valuable timber tree, and of late years the locust borer rarely troubles it.

Shaping young trees may be easily effected if taken in time, by summer pruning and pinching. A needless or misplaced shoot, which might become a conspicuous distortion if left to grow, is rubbed off with the thumb when an inch or two long. Branches which are running out too long are stopped by pinching off the ends. By these means a handsome and symmetrical head is easily given to a young tree, if taken in time.

The Spanish Marriage Stone.

If Ireland has its Blarney Stone, which assures to any one kissing it uncommon eloquence and persuasiveness—"blarney," in fact, for there is no other equivalent for the mysterious gift—Spain has her "marriage stone," the virtues of which are equally remarkable; for any single person, male or female, who touches it, is absolutely sure to be married within a twelvemonth. The stone forms part of the masonry of the college of Sacra Monte, in Granada. About twelve months ago, two young ladies paid a visit to the old Moorish capital, and were shown over the college by one of the resident clergy, who acted as cicerone, and who treated the fair visitors with unusual deference and respect. When they came to the "marriage stone" the padre smilingly explained the peculiar powers with which popular superstition credited it. "Touch it," said one of the ladies to her sister, who laughed incredulously, but followed the advice none the less—touching the stone, not once, but twice or thrice. Now, the two young ladies were the Spanish Infantas, Dona Isabella and Dona Paz; and the latter it was who touched the stone. She did so on the 3rd of April last year, and she was married to Prince Louis, of Bavaria, on the 2nd of April of the present year.

The Girl on a Tricycle.

The girl on a tricycle has already made her appearance at the summer resorts. As observed at Newport she sat between the two wheels, which were connected by a short axletree, on a kind of saddle—astride of it, but not so circumstanced as to make divided garments necessary, as in riding horseback, man-fashion. Her feet reached down to the treadles, and her hands were employed in steering by means of a device connected with a low front wheel. Her posture was not that of sitting, however, but her figure was suspended nearly perpendicular, and her legs were moved a great deal like those of a horse afflicted with springhalt or a swimmer treading water. Her knees came up high, with an action more productive of good exercise than of grace. And yet she was "a symmetrical and pleasing traveller." The prescribed costume is soft, thin flannel, with a blouse waist and a skirt reaching just to the gaiter tops. It is obvious that the latter level could not be steadily maintained, in view of the high treading required to work the tricycle, without some special modification of the garment. This want has been supplied by taking an idea from the equestrian habit. Lengthwise of the skirt in front two gussets are set in at points where the knees will protrude into them in rising.

Incombustible Paper and Inks.

Asbestos of the best quality is treated with potassium permanganate, and then with sulphuric acid; 95 per cent. of such asbestos is mixed with 5 per cent. of wood pulp in water containing borax and glue. A fire-proof ink is made of platinous chloride and oil of lavender, mixed, for writing, with Indian ink and gum, and for printing with lampblack and varnish.

Scientific News.

—The thirty-second meeting of the American Association for the Advancement of Science was held at Minneapolis, Minn., beginning August 15th, and closing August 21st. Prof. C. A. Young, of Princeton, presided.

—When a kerosene lamp is turned down low, the small flame is not sufficient to cause draft enough to ensure perfect combustion, and the result is the diffusion of vapors, the effects of which upon the health are well known to be evil. It is not a safe practice.

—Sea water differs a little in weight at different places, but at the same spot it is nearly the same at all depths. It may be estimated at sixty-four pounds to the cubic foot, or 1¾ pounds per cubic foot more than fresh water. The additional weight is chiefly common salt. Salt water freezes at 27° Fahrenheit.

—A new vegetable parasite, *Haplococcus reticulatus*, has been recently discovered in pork by Dr. Zopf. It occurs in from thirty to forty per cent. of the animals examined. Would it not be well if we paid more attention to the sanitary legislation of Moses, a fragment of the ancient medical law of Egppt?

—The Volta prize of $6,000 will be awarded by the Academy of Sciences, Paris, in December, 1887, under the decree of June 11, 1882, for the discovery or invention of whatever shall render electricity applicable economically to one of the following objects: Heat, light, chemical action, mechanical force, the transmission of messages, or the treatment of sick persons.

—Prof. W. F. Barrett, of Dublin, has been making some interesting experiments to test the correctness of the discovery claimed to have been made by the late Baron von Reichenbach, viz., that a peculiar luminous effect resembling a faint electric discharge in rarified air, emanated from the poles of a magnet, and was rendered visible in a perfectly darkened room. These new experiments confirm those of Reichenbach.

—London papers say that "the Secretary to the Royal Botanical Society recently tried the novel experiment of planting sea weeds in ordinary earth. It would naturally be supposed that these ocean plants would not flourish away from their native element; but this is not the case, most of the specimens planted having grown admirably in soil which is constantly kept in a moist condition." The result is both curious and suggestive, and worthy of trial this side of the ocean.

—An interesting experiment, illustrating the force of inertia and molecular resistance, is given in *La Nature*. It was first performed, and with a practical purpose, by a Corsican, under the second empire. Place a sealed piece of wax on an anvil, or well-supported iron plate, and over it a round ball of cast lead (not compressed), of diameter corresponding to its width. Now give the ball a sudden violent blow with a hammer. The flattened ball is found to have taken the impression of the sealed wax in its least details, and without breaking it (if the experiment is properly done). With the aid of this matrix the seal may be copied.

—Researches relating to sounds produced by a stream flowing through a circular hole at the lower end of a long tube containing liquid have shown that the pitch does not change gradually, but that a definite number of distinct notes are heard successively as the liquid column shortens by the outflow. The pitch depends on the length of the liquid column and on the velocity of efflux. The number of vibrations is proportional to the velocity of efflux; and the sound is pure only when the sound of the vein is one of the proper sounds of the liquid column. A column of constant length gives notes in a harmonic series. When the sound is reinforced by the column of air above it becomes quite loud. If the walls of the tube are prevented from vibrating, the sound ceases. The relative velocity of sound in different liquids may be determined by finding the lengths of the columns of liquid which give the same note, and the results thus obtained will be found to agree very well with determinations by other methods.

Practical Hints.

—To make a black dye for wood, first sponge the wood with a solution of chlorhydrate of aniline in water, to which a small quantity of copper chloride is added. Allow it to dry, and go over it with a solution of potassium bichromate. Repeat the process two or three times, and the wood will take a fine black color, unaffected by light or chemicals.

—The government method prescribed for cleaning brass, and in use at all the United States arsenals is said to be the best in the world. The plan is to make a mixture of one part common nitric acid, and one-half part sulphuric acid in a stone jar, having also ready a pail of fresh water and a box of sawdust. The articles to be treated are dipped into the acid, then removed into the water, and finally rubbed with sawdust. This immediately changes them to a brilliant color. If the brass has become greasy, it is first dipped into a strong solution of potash or soda in warm water; this dissolves the grease, so that the acid has free power to act.

—A new screen, or corner stand, consists of an excellent imitation of a turf with a portion of a mahogany picket fence and gate arising from it. The gate is padlocked with a steel hasp and lock, and has steel hinges. Over the gate climbs a fox having in his mouth a hare that he has evidently caught in the garden, from which he would escape. A vine growing up on either side the

gate adds to the delusion. The entire thing is about five and a half feet tall. A tripod from which to suspend a basket of flowers, is made from a hoe, rake and flail crossing each other near the top and having a sickle carelessly attached at this crossing point. Others are made of oars, sculls and boat-hooks.

— A Paris correspondent writes that crocodile-skins are now combined artistically with plush for photograph frames. A broadish flat frame with beveled edges is decorated with either gilt tooling as used in bookbinding, with colored leather mosaic, or with a metallic application in high or low relief, whether a design or a garland of flowers. The application does not surround the frame; it occupies one corner only, and runs half way up and along two sides of the frame. Plush, with the grain of Morocco or Russia leather, is employed very effectively in these frames. Again, you may have an entirely metal frame reproducing the grain of the plush or of the leather with the application of flowers. The progress of galvansplashe and the employment of metalized plants as natural models enables articles of this composition to be produced very cheaply.

Notes and Queries.

In continuing this department, which has been found of so much value, we would remind our readers who wish for information on any of the arts and sciences, that they are cordially invited to make their wants known through this column, and those of them who can furnish accurate answers to questions asked are requested to send in replies. Doubtless many of our subscribers may know of methods, processes, or devices that may be better or more suitable for the particular case in question than anything generally known, and it is this reason that induces us to keep this department open for a medium, where an interchange of ideas and practices may be made to the advantage of all our readers. Correspondents will please send their full address when forwarding their communications—either questions or answers—not for publication, unless expressly so stated, but so that we may know where to find the writer if desirable. Communications should be sent in on or before the first of each month previous to publication, to insure insertion in next issue.

Answers.

104.—Buy your tools of a good maker. Avoid cheap article —especially edge tools. If you purchase of any good maker or dealer, several of which advertise with us, and a fault is afterwards found, the tools will be exchanged. In fitting up a workshop, purchase your implements as you require them; by doing so you avoid unnecessary expense. If you are only a beginner, do not attempt to grind your tools; have them ground at some tool shop, the cost for each is only a trifle; if you think you can grind them yourself, buy a good stone at once, and always grind with the stone running towards you, otherwise you will have a wire edge. Do not sharpen your gouges on an oil stone, or you will not be able to sharpen your chisels properly; use a slip for the gouges, a flat stone for the chisels and plane-irons, a small slip for inside tools. If a new gouge slip be purchased, a good plan is to make a wide groove with an old file in the place you wish to sharpen your gouge; by doing so you obtain a straight groove, and possibly prevent cutting the fingers. In sharpening the tool do not hold it above the place where the gouge passes backwards and forwards, or a slip may occur and a nasty cut be the result. The best stones for turners and carvers are Turkey, Arkansas, and Washita stones. We do not think anything is better than a good piece of Turkey, but opinions differ, and some prefer Washita. Both are good for fine work. For coarse work, the Arkansas stone will be found very useful.—Ed.

105.—A writer in *Knowledge* describes a method of taking the impression of leaves and flowers as follows:—Procure a small bottle of oil (I always use olive), a camel's-hair brush or a piece of rag, half a dozen sheets of white unruled copying paper, a few sheets of white note paper, and a good old-fashioned tallow candle with a large wick. Take the leaves you wish to perform upon and put them under a press or in a large book, so as to get them with a fairly even surface. Then take a large sheet of copying paper and oil it completely by rubbing it with your rag, taking care not to put on more oil than is necessary. When this oiled paper is fairly dry hold it over the candle so that the flame just touches it, moving it about to prevent scorching. Do this until a fine layer of carbon, equally black everywhere, is deposited. When the light of the candle can just be seen through the carbon lay the paper on a table with the black side uppermost. Then place the leaf between a piece of the black paper cut to the proper size and another sheet of paper. After rubbing the upper sheet carefully, place the leaf between two clean sheets of paper. By again rubbing the upper sheet a complete impression of the leaf, with even the most minute veins marked in black, will be produced upon the sheet of paper. If this is allowed to dry it will not smear, and will always retain its freshness. Care should be taken not to allow the leaf to be chipped while on any of the sheets of paper.—X.

106.—There is a way of squaring numbers by complement and supplement, if that is what you mean by the American system. We first met with it in a little work called "Lightning Arithmetic," published in San Francisco by G. Frusher Howard. You take the ten next before the number, add to the number to be squared the difference between it and the ten, multiply that by the ten, and then square the difference you got at first and add it to the result. Thus to square 13 you take the nearest ten behind it, which happens here to be 10, subtract it from 13, and get 3; then you add 3 to 13, and multiply by 10—in other words, $13 + 3 \times 10 = 160$; and then you add the square of three, namely, 9, so that the full calculation runs $(13 + 3 \times 10) + 9 = 169$. In large numbers the gain is great, thus—1007 squared $= (1007 + 7 \times 1000) + 49$, or 1,014 049. This is called squaring by supplement: squaring by complement is taking the ten next in front of the number, and subtracting instead of adding. Thus 993 squared would be $(993 - 7 \times 1000 + 49 = 986{,}049$.—California.

107.—The following hints regarding pigeons may be of service to "Subscriber," though, as a rule, pigeons will thrive and multiply under any reasonable conditions: The loft should at this time of the year be kept as tidy and clean as possible, and care should be taken that the fountains and food utensils are clean as well. Nothing is so likely to breed disease as polluted water. Fresh rain-water is better for the birds than hard or river-water, but let them have it in abundance. Continue summer feeding, and do not forget the salt-cat or salt earth so necessary for the health of the birds. This is best placed in a small box kept for that purpose, and constantly replenished when empty It may be composed of three parts of old lime rubbish—which can generally be easily enough procured from any place where building is going on—and one part of coarse salt, with a little dry clayey earth. See that your pigeon loft has plenty of fresh air; if it has not, some plan of ventilating should be adopted forthwith. A good layer of sawdust with which a little

turpentine has been mixed, if placed in the nests, is a good preventive against vermin.—SAM R.

107.—The Camera Lucida is simply a four-sided bar of glass, with two of its faces at right angles to each other, and the other two at an angle of 135°. The glass is held with the right angle upwards, and the eyes being directed down upon the surface, see, reflected from the sloping sides, the object down the tube of the microscope, or whatever the instrument may be. A Camera Obscura is a rectangular box with a lens, whose focal length is equal to the length and depth of the box. This has a reflector fixed at half a right angle behind it, and this throws the image of the object towards which the lens is directed on to a piece of ground glass fitted into the top of the box.—Z.

Queries.

108.—I want to do some gilding of letters and ornamental work on glass, and if some fellow-reader who is "up to the business" will give me a little information on the subject, he, or she, will confer a favor on an AMATEUR.

109.—How are sea-shells bleached and made to look so clean?—SADIE.

110.—Please answer the following question through the YOUNG SCIENTIST: If a large dwelling, containing nineteen rooms, besides kitchen appointments, and is standing apart from any other building, and is surrounded by trees and shrubbery, is it not a villa?—DISPUTE.

111.—A few hints from any competent reader on the construction of an Æolian Harp will be thankfully gobbled up by a young WOOD-SPOILER.

112.—Will some one kindly explain to a dull boy what is meant by *specific gravity*, and oblige an old subscriber.—JUMBO.

113.—Is it known when the manufacture of glass first began?—ANTIQUARIAN.

114.—I would be pleased if some reader of the YOUNG SCIENTIST would inform me who wrote the following lines:—

"Yes, this is Love, the steadfast and the true,
Th' immortal glory which hath never set;
The best, the brightest boon the heart e'er knew;
Of all life's sweets the very sweetest yet!
O, who can but recall the eve they met
To breathe, in some green walk, their first young vow,
While summer flowers with moonlight dews were wet,
And winds sigh'd soft around the mountain's brow,
And all was rapture then which is but memory now."

—KATIE B.

Market Report.

Retail Prices.

IMPORTED CAGE BIRDS.

Canaries, *Belgian*, per pair	$6.00 to 15.00
" *French*, per pair	6.00 to 15.00
" *German, Hartz Mts.*, each	2.50 to 10.00
Gold Finches, each	1.50
Gold Finch (mules), each	2.50 to 5.00
Bull Finches, not trained, each	2.50
Bull Finches, trained to sing two tunes, each	10.00 to 40.00
African Finches, per pair	2.50 to 5.00
Chaffinches each	1.50
Talking Mino or Mina	10.00 to 25.00
Linnets, each	1.50 to 2.00
Linnets (mules), each	2.50 to 5.00
Green Linnets, each	1.50
Java Sparrows (blue), each	1.50
Java Sparrows (white), per pair	6.00 to 8.00
English Sparrows, per pair	1.00
Siskins, each	1.00
Gray Cardinal, each	4.00 to 5.00
Nightingales, each	8.00 to 25.00
Japanese Nightingales, each	5.00 to 10.00
Thrushes, each	5.00 to 7.00
Skylarks, each	5.00
Troopials, each	7.00 to 12.00
European blackbirds, each	5.00 to 7.00
Black-caps, each	4.00
Starlings, each	4.00 to 6.00

PARROTS.

Gray Parrot	10.00 to 15.00
Single Yellow-Head Parrot	8.00 to 12.00
Double Yellow-Head Parrot	10.00 to 15.00
West Indian "	4.00 to 5.00
Cockatoo (white)	18.00
Australian Shell Paraquets, per pair	6.00
"Love Birds," African Paraquets, per pair	6.00
West Indian Paraquets, per pair	3.00 to 5.00

All birds that are accomplished singers or talkers bring high and "fancy" prices. Parrots are rated by the number of words, sentences, and tunes they have learned.

AMERICAN CAGE BIRDS.

For all information on this subject, as to reliable dealers, etc., etc., send postal card to YOUNG SCIENTIST. When desired, the goods can be sent through this office, but in all cases remittances must accompany the order.

EXCHANGES.

Only those who are *yearly* subscribers, and whose names are entered on our books have the privilege of inserting exchanges.

Exchanges must be on separate slips of paper or postal cards. If mixed with business matter in letters or cards they are filed away and never reach the printer.

Exchanges must not exceed thirty words.

Buying and selling belong to the advertising department.

We reserve the right to omit the exchange column, when we have not room for it, and the amount of space at our disposal will regulate the number of insertions given to each *exchange*, the preference being always given to those who have not previously used our columns.

A number of first-class tricks, trick books, stamps, coins, Confederate money, curiosities, etc., to exchange for stamps or pet stock, such as rabbits, Guinea pigs, or squirrels. J. S. Reese, 52 Cedar St., Canton, Ohio.

Shell boat, Spanish cedar, 28 feet long, spoon oars; good order; been used but little; for offers. J. W. B., Carmel, N. Y.

Rowing machine, cost $10; photographic outfit, $16; Flobert rifle, $15; medical battery, $10; "Wood's Botany," etc.; for elk horns, deer horns, minerals, Indian relics, and all kinds of curiosities; would like list of curiosities from dealers. Chas. C. Collier, 3617 Locust St., Philadelphia, Pa.

Vol. III. of the *American Machinist* for the best offer of minerals. J. A. S., P. O. Box 83, East New York.

I have five or six complete years of the *Galaxy* (magazine) also a number of odd copies; I will exchange the lot for an induction coil in good condition, and giving at least a ¼ in. spark. W. B. Greenleaf, 480 La Salle Ave., Chicago, Ill.

I have eighteen numbers of the *Harper's Young People* (79 to 96 inclusive), containing part of the story "Tim and Tip," by James Otis, and all of the story "The Cruise of the Ghost," to exchange for a good spyglass, a good bull's-eye lantern, or a small telephone. J. H. Gamsey, Box 25, Wilmington, Will. Co., Ill.

A good violin, bow, box, books, all complete, worth $12.00, to exchange for Wood's Botany, Young Mechanic, or scientific books and papers; send list. A. D. Chamberlain, Trout Creek, Del. Co., N. Y.

A model self-inking printing press, chase 2½ x 3¼, 4 fonts card type, 3 type cases, ink, roller and furniture all in good order, to exchange for a good silver watch and nice chain. G. E. Wilmot, Box 88, Lebanon, N. H.

Any person wishing to exchange foreign stamps please send sheet and I will return it with mine. Box 90, Melrose, Mass.

New Nickels (without "cents") for offers; I also wish to exchange with curiosity, coin and stamp collectors residing in foreign countries. G. S. Griffin, Moline, R. I. Co., Ills.

1 Sea bean, 1 alligator's tooth, 1 small cocoanut, 1 liver bean, lot of other beans and shells and 50 foreign stamps for a printing press and outfit, size of chase about 6¼ x 4 inches; send postal. Geo. O. Riphard, Westminister, Md.

W. C. Roseboom, Cherry Valley, N. Y., wishes to exchange with amateur photographers, or others; photographs and pictures taken by themselves, mounted or unmounted; give name of picture and camera.

I would like to exchange minerals, stamps and curiosities for the same. O. J. Lache, 1313 Poplar St., Philadelphia, Pa.

6 fonts type, 4 cases, 2 composing sticks, leads, rule, etc., outfit except press, to exchange for good tent, not less than 6 x 6, or offers; send card before exchanging. Wm. O. Brown, Middlebury, Vt.

I have double barrel muzzle-loading shot gun, watch, orguinette, harmonica, stuffed birds for Household microscope, photo. outfit, books on natural history; specimens or offers. E. O. Tuttle, Bristol, Vt.

A printing-press, chase 5½ by 7 inches, in good order; will exchange for a large self-inking press or type. A. W. Barrett, Canajoharie, N. Y.

A one-keyed flute and pair of No. 10 club skates for rifle; E-flat cornet, cost $25, for an eight or six-keyed flute of equal value; all good; or offers. J. L. Pilkington, Pearsalls, L. I.

For fossils or minerals; fine specimens of Pentremites—two varieties—from sub. carb. rocks; also Flobert rifle, in good condition, and McKinnon pen. M. H. Crump, Bowling Green, Ky.

I have for exchange a collection of about 80 species of fine fossils, all named and making a fine collection, which I wish to exchange for opera glass, microscope, telescope, or offers; correspondence solicited. A. Stapleton, Box 756, Seneca Falls, N. Y.

Wanted, amethyst, moss agates, trilobites, geodes, coral, and coal ferns in exchange for fifty Indian arrowheads, coquina rock and Florida moss. E. V. Sheerar, Wellsville, N. Y.

"Crystallography" (40c.); "Electricity" (40c.); "Selection and Use of Microscope," abridged, (30c.) Either in exchange for "Workshop Companion," or two for "The Microscope," by Ross, or offers. C. H. Denniston, Pulteney, N. Y.

Home Medical Battery, cost $7; Lemair's Field-Glass, No. 2202 of Queen's Catalogue, cost $15.50; Achromatic Spy-Glass, power 25 times. To exchange for books or offers. Emerson Heilman, Heilmandale, Pa.

A small collection of coleoptera, comprising 100 species and 300 specimens, all correctly named, in exchange for bird-skins, insects, books, or eggs. Emil Laurent, 621 Marshall St., Phila., Pa.

A small magic lantern, Ruby pattern, with twelve slides, for a good book on Entomology, with illustrations. Willie R. Hotchkiss, Morrisdale Mines, Clearfield Co., Pa.

Wanted, Thompson's "Witchery of Archery." Must be in good condition. Write before you send. J. Anthony, Jr., Coleta, Whiteside Co., Illinois.

A telescope worth $3.50, for a self-inking printing-press and outfit; chase not less than 2½ by 3½ in. Eddie Judd, 260 Connecticut St., Buffalo, N.Y.

To exchange for offers: $20 scroll-saw, Seneca Falls make, $4 Bailey circular plane, set of Auburn metallic planes, brass-bound four-foot rule, fourfold, Traut's patent combined plow, dado, etc., cost $7. F. A. Rappleye, P.O. Box 12, Farmer Village, Seneca Co., N.Y.

Bee Hive wanted; one of the old-fashioned straw "skeps"; say what you would like in exchange. Apis, care of Young Scientist, 294 Broadway, N. Y.

A first-class type writer, in excellent condition, cost $125.00, to exchange for good microscope, telescope, or valuable scientific books; send full particulars. A. B., Box 114, Lewiston, Maine.

A $30 stencil outfit (Spencer's) for a self-inking printing press in good condition, chase about 6 x 9; rich ores and minerals of Idaho for scientific and instructive books, printing press, type, etc. J. P. Clough, Junction, Lemhi Co., Idaho.

Wanted pyrites of iron from Colorado gold mines in exchange for sea shells and other gems; send list of what you have to exchange. S. Ferguson, Eureka Springs, Arkansas.

A banjo in good condition, two pairs of rosewood bones, three splendid games, and a fine set of drawing instruments, for a good cornet, viola, violincello or double bass. L. B. Hill, Kalamazoo, Mich.

Scientific specimens of various kinds for same. Geo. E. Frazier, Caldwell, Ohio.

Lester W. Mann, Randolph, Mass., Box 162, has Demas scroll saw, lathe and tools, emery wheel; $20 worth patterns; Smithograph; large harmonica, cost $1.75; novelties in seeds; for large self-inking press or offers.

10 volumes Chambers' Encyclopædia, American Book Exchange edition (cloth); Bonanza printing press, chase 3 x 5, card type, ink roller; spyglass, power 10 times; for French triplet, 1-5 in., or offers. H. P. Nichols, P. O. Address, Bridgeport, Conn.

A good telescope, also foot-lathe and saw combined, each worth $10 00, for shells, fossils or relics. Independent, Conncautville, Crawford Co., Pa.

Birds' eggs to exchange for others; send list of what you have to exchange. Emil Laurent, 621 Marshall St., Philadelphia, Pa.

Twelve or fifteen volumes of the American Agriculturist to exchange for scientific books or offers. W. H. Osborne, Chardon, Ohio.

How To Make Rubber Stamps.—II.

VULCANIZATION OF THE RUBBER.

THE plaster cast being now quite dry, our amateur stamp-maker may at once proceed with his work. If the stamp in hand be a very particular one, or if a large number are required—all to be cast from the plaster and of one pattern—it is usual at this stage to soak the cast for a few minutes in a weak solution of ordinary gum shellac and methylated spirit—a few cents' worth of each will be sufficient. This mixture fills up all the pores of the plaster, and leaves on it a polished and very smooth surface, besides making that fragile material almost as hard as a stone. But for ordinary work this process is quite unnecessary; in fact, it is rarely, if ever, employed, unless in the manufacture of very expensive stamps, such as daters, etc., which are expected to last for half a lifetime.

In either case the cast is now taken and replaced in the frame. Take two pieces of the specially prepared india-rubber, which is supplied in suitable sheets, cut them to the size of the stamp you require, and place them, one on top of the other, on the cast, rubbing the side next the plaster, and the back of the upper piece, with a little French chalk; but be extremely careful that none gets in *between* the pieces. Over the top piece put a piece of paper, about the size of the rubber or a little larger. Over all place plate like Fig. 1, with the pins turned downward, and square with the edges of the frame. Place this "pile" in the press, Fig. 2, carefully, keeping the edges square, and the centre of the pile directly beneath the screws, which you may tighten a little, to keep its component parts from moving about.

The vulcanization of the rubber, as it is called, may now be proceeded with. It is just as well to understand the "why"

and "wherefore" of this process, as it may truly be said that more time and money have been wasted in this part of the manufacture than in any previous part of the process. It consists, then, in applying heat to the india-rubber under pressure, in such a degree as to expel the sulphureous gas which permeates it, and no more. This has the effect, firstly, of turning the color of the caoutchouc to

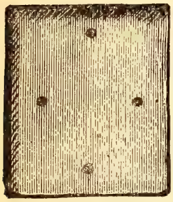

Fig. 1.—PLATE.

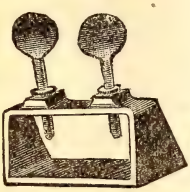

Fig. 2.—PRESS.

that slaty tint with which we are all so familiar; secondly, of rendering it beautifully elastic and pliable; and thirdly, to permanently retain the impression which has been imparted to it. The success of the operation depends in a small measure on the skill of the operator, and nearly altogether on the india-rubber employed. It is a mistake to endeavor to procure it at an ordinary rubber dealer's; they are ignorant of the use for which it is required, and thus may supply the purchaser with a wrong kind; or if they do happen to have it in stock, it will be very probably in the form of large rough blocks, utterly unsuited for the purpose.

Place the whole apparatus—press, frame, plates, and rubber, over a clear fire or a gas burner, whichever be most convenient. A Bunsen burner, size 2, in practice, will be found to be the best in the long run, the absence of soot and smoke being a very important item in the work. In this case the apparatus must be placed on an iron tripod, which may be bought at most druggists for twenty-five or thirty cents.

In either case, do not touch the press until the heat has thoroughly penetrated every part of it, which will take two or three minutes; then, taking an old piece of cloth between the fingers, gradually, carefully, and *evenly* screw down the press, at short intervals, until the four pins on Fig. 1 penetrate right through the layers of india-rubber, and at last rest on the upper edge of the frame. The press is now quite tight, and the screws can no longer be used; and now the operator can examine the rubber, a thin edge of which will be exposed between the plates. As soon—generally in about fifteen minutes—as the rubber turns to a blue color, it is a sign that the vulcanization is complete; and the whole apparatus must now be removed from the source of heat, and, with the parts still together, left to cool; or, if expedition is necessary, it may be placed in cold water. When it is quite cold, unscrew the press, take out the frame, with the rubber still adhering to the plaster in it, and carefully separate the rubber from the cast; they may stick together slightly, but it is only a chance. When separated, you will find that you have produced an absolutely faultless fac-simile in vulcanized caoutchouc of the original leaden type you used; in other words, you have made a RUBBER STAMP.

The only thing that now remains to be done is the mounting of the rubber on the brass or wood, as the case may be, fixing the same in a handle, and placing the whole in a box, with the pad and ink necessary for its manipulation.

The piece of brass is taken, and, by means of the square shank turned on it, forced into the hole in the handle; the rubber is then, after the edges have been trimmed with a pair of scissors, cemented on the brass with a thick solution of methylated spirit and gum shellac; it will be dry in one or two hours.

The cheaper stamps are all fastened on wood, which answers nearly as well as brass. Glue or cement may be used for attaching the rubber to the wood.

In the case of an oval or round stamp being required, an oval is bought of the size chosen, at a dealer in printer's materials, and being type high, and the centre and edge being left blank, or "pierced for type," the letters are put into it and wedged in their places by little pellets of tissue paper, small leaden spaces, or anything handy.

In practical business, half-a-dozen or more stamps are made at one operation, the wording of each being arranged as required, and the types put into the chase alongside of one another, so that name stamps, ovals, square stamps, and round will be next-door neighbors. A plaster-cast is then taken in the usual manner, as if only one stamp were being made, and a similar cast in india-rubber; the various stamps are then cut and separated from one another with a pair of scissors.

Overglaze Painting on Porcelain.—III.

BY AURELIO DE VEGA.

IN purchasing brushes to operate with, some care is necessary, and the following hints will doubtless be of service:

18. *Testing Brushes.*—Whatever kind may be selected, the best only of that kind should be used. It is impossible to produce a highly-finished work with bad tools. In a good brush, when dry, the body is perfectly elastic, and the hairs have a perfect spring, and lie equally together.

A brush should not be purchased without having been tested. Always test your brushes in water. If the seller does not proffer the jar of water, ask for it; if he does not produce it, do not buy. The water forthcoming, dip the hairs in it so that they become fully charged. Then holding the handle tightly between the ends of the thumb and second finger, suddenly depress the latter, retaining the brush between the thumb and the first finger. This jerk will send off the superfluous water, and then the brush, if good, will at its end present, if a round or small flat one, a fine point, if a large flat one, a fine, straight, or slightly-curved line, to which, in either case, the body has *regularly* decreased. If a round brush should, after this test, have protruding hairs in the body, or free hairs at the end, or a flat one have some parts of its line thicker than others or depressed, or the terminating point or line be not led up to gradually, reject it without further consideration; it is not a good brush.

19. A common test is to moisten the brush slightly in the mouth, and draw the hairs together through the lips. This is a procedure giving most uncertain results, not to mention an obvious objection to it. In a brush not absolutely worthless, but a long way from being thoroughly useful, the stickiness communicated by the saliva would impart to the hair-tips a certain amount of cohesion, causing a point which under the proper test would never form.

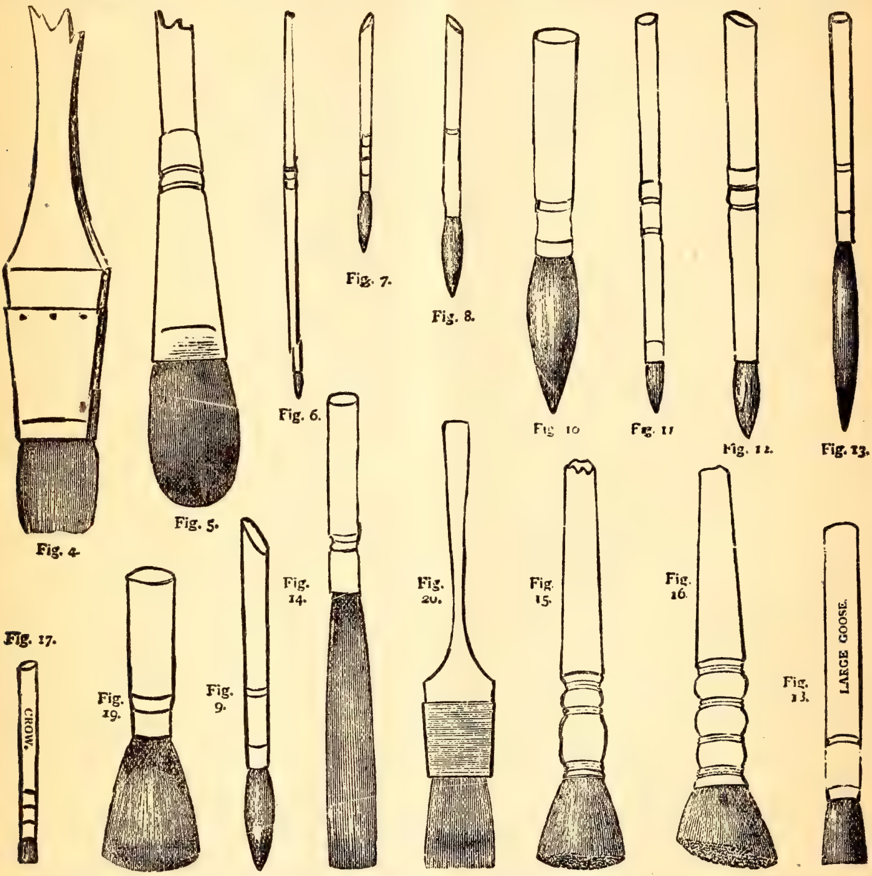
20. One further caution is necessary, and is addressed rather to those living in the country. It may be that a piece of work is in hand which it is desired to finish quickly, but through some accident the suitable brushes have become useless. For convenience, application for new brushes is made at the nearest shop professing to sell artists' materials. Now, a good many of the small and pretty numerous shops which make this profession act up to it, and at them serviceable tools may be obtained; but others, I am sorry to say, do not, and at these one may meet with brushes already presenting a very good point, which, alas! is more frequently than not the result of the addition of a little mucilage to the water with which the hairs have been moistened. In this case the hairs are a trifle harsh and stiff. If you cannot conveniently search elsewhere, rub the brush between the fingers to remove the powder, and test with water as above suggested. A good one may possibly be found among the lot.

21. *The Shape and Size of the Brush to be employed.*—These particulars will depend upon the nature of the work and the extent of the surface to be covered, and hence there is great variety in these respects.

22. *Skies, Water, and Grounding.*—For skies, and water in which there is a pretty large sheet of color, either of one intensity or graduated, and to be left as laid, or to have the clouds or lights picked out, a flat brush, as shown in Fig. 4, is generally about the best; but in smaller or somewhat irregular work, that shown in Fig. 5, which is often called a sky brush, is perhaps most serviceable. The size should be such as to allow of enough paint being

taken up to give a complete line of full width. Fig. 5 is also well suited for washing in large masses of foliage. Either brush answers well for backgrounds or ground-laying.

23. *For General Use in the ordinary run of Painting,* the brushes or pencils depicted in Figs. 6 to 12 will be found most two smaller than that represented, are useful in large shading, such as broad draperies in big paintings, and in foregrounds. Fig. 11 is a shortish, flat sable, highly useful in giving crisp touches with paint rather stiffer than usual. Fig. 12 is an ordinary round sable. Both these last are in metal settings. With regard to



BRUSHES.—Figs. 4, 5—Water or Sky, Washing In or Grounding Brushes. Fig. 6—00 Miniature Sable. Fig. 7—Small Finisher, Camel Hair. Fig. 8 - Small Rose, Camel Hair. Fig. 9—Special Rose, Camel Hair. Fig. 10—Large Shader, Camel Hair. Fig. 11—Flat Short Sable. Fig. 12 - Round Ordinary Sable. Fig. 13—For Lining or Tracing. Fig. 14—Bander. Fig. 15—Dabber, flat top. Fig. 16—Dabber, skew top. Figs. 17, 18—Superfine Fitch Hair Brushes. Figs. 19, 20—Softeners.

serviceable, the sizes varying according to the size of the work in hand. Fig. 6, an extremely fine sable, is for the most delicate work in the features of small faces, such as nostrils, lips, the iris, etc. Figs. 7, 8, and 9, in quills, are of sizes very generally useful. Fig. 10, and a size or the difference between round and flat brushes, it may be stated that the latter are often a little more useful in a skilled hand, as a greater variety of stroke and touch can be given with them. This point will be further noticed by and by. Both sables and camel-hair may be ob-

tained in quills or set in metal or albata. The first are the cheapest, and are of excellent quality. The last, no doubt, look best, and in the very small sizes are rather preferable, as greater care is supposed to be taken in the fixing, etc., of the hair. The metal does not corrode.

24. *Liners, Tracers, and Banders.*—Fig. 13 represents a brush known as a liner. This has very long hair, and is a fine and very supple brush, capable of holding, for its diameter, a very large quantity of paint. This is a necessity met by the length, as otherwise the point would be likely to dry. It is used for drawing circular lines round plates or vases, and may be had in three or four sizes. A somewhat similar brush, with shorter hair for the same diameter, is made for tracing and drawing outlines. With a little practice either answers very well for the other. Fig. 14 also comes into use in circular work, and with it bands of color are described. The possession of it is not, however, an absolute necessity, as with experience a large liner can be made to do its work. These brushes should be of a size that when well filled will enable the painter to do a complete circle, whether line or band, without stopping to have to replenish the brush.

25. *Dabbers.*—The foregoing are brushes used in actually laying the paint on the ware. There are others required for distributing it *when such an operation is necessary.* These are Fitch brushes, or Dabbers, and Softeners (see Figs. 15 to 20). The former are employed to render even a coat of paint which it is perhaps impossible, owing to irregularities in the surface of the ware or from some other cause, to lay quite flat with the painting brush. The large ones are in two shapes. The flat-headed ones are for use on flat or convex surfaces, such as the middle portion of plates and dishes, and the round of vases, etc. Those with a skew top, which is slightly convex, are for concave parts, such as mouldings of plates and other hollows. These two kinds are for ordinary work. The small fine ones set in quills are for more delicate work.

26. *The Softeners* are brushes with very fine and soft hair, and, as their name implies, are used in softening tints and rendering them more delicate, and are most serviceable in such work as toning down the edges of clouds, producing graduated tints which vanish or mingle, one can scarcely see how, and often subsequently to the dabbers, to secure an evenness which they may fail to produce, and for which other processes that we shall have to notice are unavailable. These are made in badger and camel-hair, the former being a most excellent kind, and round or flat. Fig. 19 shows a round camel-hair.

27. *Cleaning* (*a.*) *Procedure.*—It may seem an excess of caution, not to say an impertinence, to urge the observance of cleanliness with regard to the brushes; and yet experience shows that it is absolutely necessary to do so, and in the strongest terms. Cleanliness is needful in everything connected with china painting, but in no department is it more so than in the treatment of the brushes. Many a good brush is ruined either by letting paint harden in it past the possibility of entire removal all at once, or by injudicious treatment after paint has dried in it. To prevent the occurrence of this condition, one course is obvious: do not let the paint harden in your brushes. Those you have used during the day, clean when the day's work is done. While they are moist the labor of cleaning is not worth mentioning, and the time the cleaning will occupy is but short; if postponed till the morrow both will have increased. The brushes will be cleaned in turpentine. Ordinary turpentine, such as is procurable at paint stores, will do quite well, provided it be fresh and not oily. In cleaning up, as in everything else, there is a right and a wrong way. If you wish to spoil your brush, to cut the hairs or make them stick out like an Aztec's or become curly like a negro's, you will dab it down perpendicularly on to the bottom of the little dish or vessel containing your washing turpentine, but if you would retain it serviceable until fair wear and tear alone renders it otherwise, you will clean it by holding it in the turpentine slantways, at the angle at which a pen is ordinarily held in

writing, and will turn it on either side, gently pressing it against the vessel so as to squeeze out the paint. The same turpentine will clean several brushes if the paints in them are allied in composition, as to which we shall speak in due course. The plan I adopt, and which I have found economical, is to have a slant tile with three divisions; put a little turpentine in each, wash each brush singly on the higher part of the first slant, and when pretty free from paint draw it along a clean piece of rag and put it on one side. It will be found that the paint sinks to the lowest part of the slant. When all are washed once, repeat the process in the second slant. If the cleaning has been thorough, the turpentine in the third slant will not be at all tinged. It is necessary to state that a trace of one color in a brush may be sufficient to spoil another with which such brush is used. Some colors wash out less easily than others; thus, blue is rather persistent, while pink is very easily disposed of, and this consideration indicates the advisability of employing different sets of brushes for colors of different classes, which are mutually antagonistic.

At the same time a slip may happen with even the most methodical, and a brush may escape notice when the rest are having their bath, so that when discovered next day or so the paint has dried somewhat. Now in such case do not on any account bend the hairs to try and soften them, as doing so will not effect the desired purpose, but may break the hairs and spoil the brush. The proper way is to let it soak in turpentine for a moment, then hold it in front of a fire, or by the side of, *not over*, a gaslight until it softens. You will then be able to wash it in the ordinary way. If through the heat the turpentine has evaporated before the brush is soft, recharge the brush and hold it to the heat again.

It may be added that an occasional mild application of a little soap and water (without soda) is beneficial to the brushes. It should be administered but seldom, however, as frequent dosing results in spreading and curling the hair.

28. *Caution.*—In one little book on this subject I find that the student is recommended to have at hand a little bottle of *spirit of wine* in which to clean the brush, probably because this liquid is such a solvent for oils. It does too much, however, in one respect and not enough in another, for it runs the oil out, leaving behind the whole, or almost the whole, of the paint in clots or fine needles closely adherent to the hair and difficult to thoroughly remove.

29. *Receptacle for Brushes.*—If the brushes are, as they should be, kept in a separate box, say of cardboard, care should be taken that the box is somewhat longer (about a couple of inches) than the longest brush in it, and that when the brushes are put away the hairs are not pressed against the end, which would turn the points and render the brushes useless.

In the next paper Mediums and Paints will be dealt with.

(To be continued.)

Amateur Boat-Building.—V.

ALTHOUGH our "Hints" relate to river craft principally, the subject comprehends not only considerable variety in the form of boats used, but also in their quality, so to speak; and taking them in an ascending scale, we shall begin with the most primitive affair in which one can navigate, and finish with the more elaborate and capable boats.

Quite low down in the scale we must place the punt, and with this we had intended to begin. But a good punt is (or should be), after all, a really "built" affair—that is to say, although keelless, it has still its skeleton—the frames which give it solidity. And, therefore, there are boats of more simplicity than even the punt; one of which—rude, but riverworthy—we will speak of first.

There is another reason for this. It was in a craft of this sort we first took to the water, and it is the kind also which many an emigrant in a new country turns out to aid him in his journeyings or fishings.

A "dug-out," some one says. No; it is

not one of Robinson Crusoe's patent. That description of article demands too much labor.

In many of the older countries a man leases the rush harvest of a river. The greater rush (*Scirpus lacustris*) is of sufficient economic value to be worth purchasing the right to cut when mature. Its principal use is by coopers, who place one between each stave of a barrel to caulk it, so to speak. It is also used for mats, baskets, thatching, etc. Well—our boat was mainly built for "rushing;" and, while it held a good load, its draught was so little that it could be pulled over the shallowest of shallows.

To proceed. Choose two sound boards, free from knots, or what the carpenters call "shakes," ¾" thick, or thereabouts, 1′ 6″, or 1′ 8″ wide, and 12′ in length. These will form the sides of the proposed boat.

(We may here state that in all sketches and descriptions the sign ′ indicates feet, and ″ inches.)

First joint one edge of each board straight with the jack or trying plane. Then, by the aid of a broad-pointed carpenter's pencil, mark on both sides of each board the shape to be given at bow and stern, as at A and B, Fig. 1 (page 300). The curvature of the former should begin at about 3′ 6″ from the end of the board, and rounding gently upwards, should leave a depth of wood of about 9″ or 10″ at the bow, as shown in the illustration. For the stern an angle of about 15° with the bottom edge of the board will do (B, Fig. 1), beginning at about 2′ 6″ from the end of the board and slanting upwards to leave a depth of 10″ at B. Instead of marking off both boards, it can be done with one only, and when this has been brought to the required shape it may be laid on the other and marked round with the pencil, or still better with the point of a sharp awl. The plane may be employed to remove the wood to the required slope at B, but for the curve at A the draw-knife is the handiest tool, with a little care.

The boards are now to be placed together with their edges level, and the exact centre of their longest edges found and marked (C) on each board, and 5 inches set off on either side of this mark at D and E.

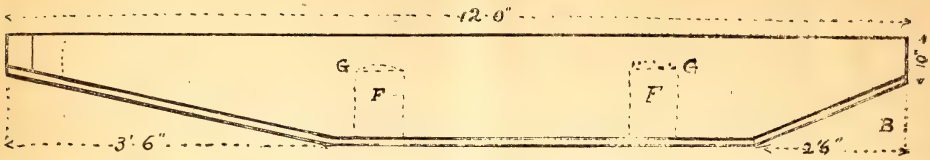
Where it is not practicable to get planks of sufficient width, two must be used for each side. In this case they must be grooved and tongued together. Two 9″ boards for each side will give rather a shallower boat than the one which we have described, or two 11″ boards, with about an inch planed off each, will make a rather deeper one. Inch red pine would do well.

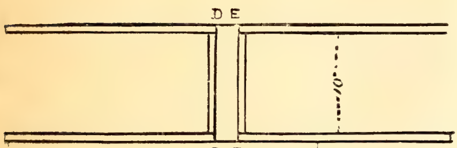
For the next step take a piece of ¾″ board 10″ wide and 3′ long. Let this be carefully squared at the ends, by the edges being first planed-up truly parallel, and the ends then marked off therefore by the aid of a square. This piece of board is to be securely nailed or screwed at each end to the edge of one of the long boards exactly above the spaces D E. Turn the pieces over bottom upwards, and nail another piece of board across the bottom precisely opposite the piece spoken of (Fig. 2).

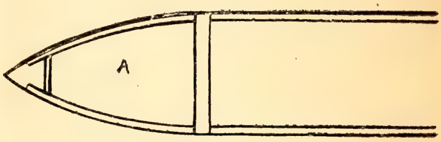
Next prepare the bow-piece (Fig. 3). This should be made of a good, hard, solid block of oak or other hard wood, thoroughly seasoned. This piece is shown by itself at Fig. 3, where A shows it as viewed from above, and B is a view lengthwise. It is triangular in plan, the two longer sides 10″, and the side which goes inside the boat 8″. Its depth should be about 11″, and it must slope off to a curve corresponding with the two boards. On each side from the inner end for a distance of 5″ the wood must be cut away for nearly 1″ in depth, as shown, which will leave a kind of rabbet for the bow-ends of the two boards to abut against. The piece of oak may now be placed between these ends, and they, when drawn close up in the recess of it, can be securely nailed thereto by large, strong nails. The affair will now present the appearance shown at A, Fig. 4, viewed from above. Copper nails are best.

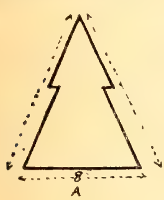
The stern-board can be now got ready. This may be 2′ long and 10″ in width, and must be, like the bow, of sound well-seasoned material (B, Fig. 4). It is to be placed between the boards at B (Fig. 1),

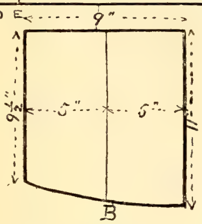
Fig. 1.

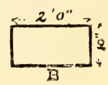


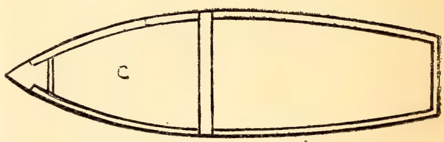


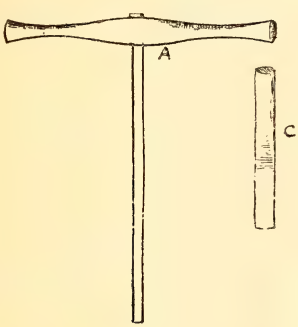












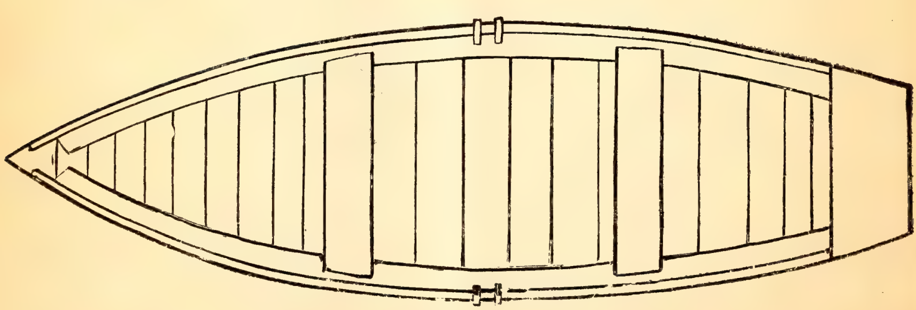


Fig. 6.

and each of the former securely and strongly nailed to it. The boat is now beginning to take shape (C, Fig. 4). Next a board, 2′ × 1′ (H, Fig. 6), must be nailed across the top at the stern, being secured both to the sides and the ends. The boat being now turned over, the bottom can be proceeded with. This is accomplished by nailing pieces of grooved and tongued inch board from side to side. It is not necessary to cut these to size first, because as the sides are safely braced together by the pieces to which they are nailed, it is not likely the application of the bottom will cause them to deviate. The bottom boards, therefore, of inch stuff, and any convenient width, may be firmly nailed on, and any surplus projecting ends can be sawn off.

When this has been accomplished, the joints require to be caulked. Oakum and pitch are the materials required; also a mallet and caulking iron. The orthodox form of these articles is shown at Fig. 5, where A is a ship-builder's caulking hammer and B the iron, or a piece of hard oak may dressed up to this shape, but the edge left broader, so that a greater length may be caulked at each stroke; but an ordinary light carpenter's mallet will do for the amateur for the former, and a fine-edged "cold" chisel, of about 6″ in length for the latter, C (Fig. 5). The oakum consists of fibres of old ropes torn asunder. The pitch must be melted in a pipkin over the fire, a little tallow having been added to it. Care must be taken that it does not catch fire, and to expedite the melting the pitch must be kept well stirred. When quite melted, a twig must be dipped in, and when drawn out with some of the pitch adhering, be plunged in cold water. Judge by the state of the small bead of pitch which clings to the end of the piece of twig. If it is brittle and easily broken, tallow must be added to the contents of the pipkin, and well stirred in. If, on the contrary, the drop is very soft and sticky, there is too great a proportion of tallow, and more pitch must be added to the mixture. By repeating the experiment the proper consistency will be obtained. The oakum must now be twisted up with the hands into a kind of loose coil, of the size the amateur judges he can force into the seams or joints to be caulked. This twisted oakum is then immersed in the hot pitch, and saturated therewith, and rapidly, neatly, and soundly driven well home in the crevices by the edge of the chisel, aided by smart, sharp blows of the hammer. The process requires a good deal of knack to do in a workmanlike way. When the pitched oakum seems inclined to adhere to the chisel, the edge of the latter must be dipped in some oil. In large seams it is sometimes necessary to go over with a second or even third paying of the pitched oakum. A thin coat of pitch may be brushed along the inside of the joints for further security. The seats are next to be adjusted. Two will be sufficient, one of which may be fixed about 3′ from the stern, and the other rather more than 4′ from the bow. The ends of the seats will require to be cut to the curvature of the side at the point selected for their positions. The seats are shown at D D (Fig. 6). They may be about 9″ wide, and 1″ stuff. For supporting the ends of the seats, two pieces of board, F F (Fig. 1), 1′ long, are screwed vertically to each side of the boat, with their ends resting on the bottom. On the upper extremities of these the ends of the seats rest, and are secured in that position by strong screws, G G (Fig. 1), which pass through the side planks of the boat and into the ends of the seats. Small pieces of stuff, about 1″ by ¼″, should be nailed across the boat under the seat, and beneath the seat across the bottom of the boat.

The stretcher or brace-piece originally nailed across the boat at D E (Figs. 1 and 2) may now be knocked off, and the craft is complete.

If rowlocks are required, they may either consist of cleats of hard wood firmly screwed on the inside of the boat, as at Fig. 6, or cut out of a couple of pieces of ash or other hard tough wood, to the ordinary shape of rowlocks and screwed on the side. Still another plan is to screw a piece of strong wood, perforated with a couple of holes on the inside top edge of each side. Into these

holes stout ash, oak, or hickory pegs about 5″ long, called "tholes," are inserted for the reception of the oars.

(To be continued.)

Hints From India.

BY W. L. D. O'GRADY.

COOLING SHADES.

During the very hot weather when President Garfield lay dying, a multitude of inventors pressed on his physicians various appliances for cooling the air of the sick chamber. Most of them were inefficient, and with few exceptions the rest were very expensive, too much so to be used in ordinary dwelling houses. Breweries have long had excellent apparatus for cooling the cellars, and some of our hospitals are equally well provided; but whether sick or well, the average resident of our cities has to submit to more or less stewing or baking during the heated term. We grumble, but do nothing to relieve ourselves, and soon cool weather comes and we forget all about the discomfort till we catch it again next year, and then we grumble again.

The inhabitants of countries where warm weather lasts longer than it does here use some very simple means to lower the temperature of their sitting-rooms. They not only keep them dark, which our proudest housekeepers do for another reason, namely, to save the carpets from fading, but use great fans, windsails, "thermantidotes," or windwheels driving air through cloths saturated with saltpetre, etc. The simplest plan of all is universal in India, where on the plains it is hot all the year round. There the *kuskus tattie*, or loosely woven mat of the fragrant fibrous roots of a shrub, is hung in one or more windows, the rest being carefully closed, and kept well wetted. The evaporation on even the calmest day soon sends down the thermometer inside the house, and the refreshing coolness is accompanied by a delightful perfume. In some parts of Italy and Spain coarse blankets are used, and if we cannot get *kuskus* here—and very little of it is imported, though it is very cheap and would surely be appreciated if better known—we might make ourselves much more comfortable by using wet blankets too.

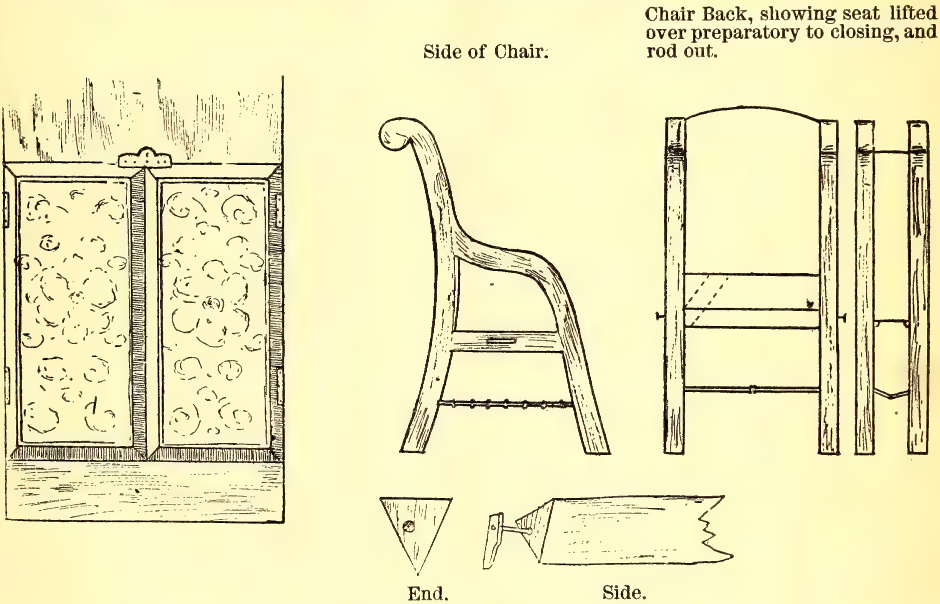
The great objection to this plan, if carried out as it is in India or elsewhere now, would be the trouble of keeping the affair properly wet, and besides, too free besprinkling with hose or watering pots would muss up the carpets. In India, where labor is very cheap, the trouble does not force itself on the attention of the people chiefly benefited, and as the floors are usually of hard cement like marble, if they are splashed it does not hurt them. There is an excellent arrangement, however, for automatically supplying the requisite amount of water for keeping the *kuskus tattie* sufficiently wet, and at the same time doing away with all possible inconvenience, which is cheap and easily applied.

A simple tin, zinc, or galvanized-iron trough is placed at the top of the *tattie* fastened to small brackets at the top of the window. It may be concealed by a lambrequin. The trough is triangular in section, the pins it works on being a little on one side. A cistern of some kind, enough to hold 24 hours supply of water, must be above the trough (unless a hose can be led to it and controlled as easily) with a small spout—a quill or tube of the same size of glass or metal would do admirably—and this should drip into the trough. When the water in the trough rises to nearly level with the balancing pins, the centre of gravity goes to the side and upsets the trough, which immediately recovers the original position when empty. It should upset every five minutes. The arrangement of this contrivance is worthy of the ingenuity of a smart boy, and the results are delightful. Dust and flies are excluded and the air is cooled. It is within the reach of the poorest.

A PORTABLE ARM-CHAIR.

Portable furniture is probably better appreciated in India than anywhere else. Officers there, as a rule, are moved about a great deal, to great distances and at intervals rarely exceeding three years, something after the Methodist discipline.

Perhaps, by the way, Wesley borrowed the idea from the East India Company. In consequence of this nomadic existence, families have the bulk of their furniture made to pack up in the smallest compass, while the very grand carved wood and marble adornments of the reception rooms go as regularly to the auction rooms as clockwork. The outgoers get somewhere near half of the value as an advance from the auctioneers, which comes in handy to meet incidental travelling expenses, and the new comers buy it at about the original price. But to return to portable furniture. Our ingenious people seem to turn out a wonderful variety of it, many of the things being attractive enough to enthuse an Anglo-Indian with bewildering delight. But neither here nor in India—till my example was followed by others—did I ever see anything that for solid comfort surpassed my portable arm-chair. When other people on the march were perched on camp stools and steamer chairs, I could take my meals with the righteous self-satisfaction of a man who has benefited himself and shown his fellow creatures how to be happy too. My arm-chair was, when fixed, so like the ordinary dining-room seat that it required considerable scrutiny to discover wherein it differed from it. When dismantled it occupied but a small space. The cane seat was hinged to one of the sides, being kept in place by an iron rod, and the back slid in grooves in the side frames. That was all there was to it. To pack it, the rod running through the sides and framework of the seat was pulled out, and the back slid out of its grooves and laid over the collapsed sides. Reversing the process produced a throne fit to bear the president of the Fat Men's Club. Of course, solid wood has to be used for a chair of this kind, no veneering being admissible, but if well made, and perhaps with some skilful carving on it, would be about as handsome a present as a bright boy could make to an indulgent father or grandfather; something decidedly useful as well as sure to excite admiration.



KUSKUS TATTIE, AND PORTABLE ARM-CHAIR.

— There is no dispute managed without passion, and yet there is scarce a dispute worth a passion.—*Sherlock.*

Chinese Foot-Rule.

A WRITER in the *North China Herald* gives some curious information respecting the foot measure in China. At present it varies largely in different parts of the country, and according to different trades; thus the foot of the carpenter's rule at Ningpo is less than ten, while that of the junk builders at Shanghai is nearly sixteen inches.

But a medium value of twelve inches is not uncommon. The standard foot of the Imperial Board of Works at Pekin, is twelve and a half inches.

A copper foot measure dated A.D. 81, is still preserved, and is nine and a half inches in length. The width is one inch.

The small copper coins, commonly called *cash*, were made of such a size, sometimes, as just to cover an inch on the foot-rule.

In the course of two centuries it was found that the foot had increased half an inch, and a difference in the dimensions of musical instruments resulted. Want of harmony was the consequence, and accordingly in A.D. 247, a new measure, exactly nine inches in length was made the standard. Among the means employed for comparing the old and new foot, are mentioned the gnomon of official sun-dials, and the length of certain jade tubes used according to old regulations as standards.

One of these latter was so adjusted, that an inch in breadth was equal to the breadth of ten millet seeds. A hundred millet seeds or ten inches, was the foot. The Chinese foot is really based on the human hands, as is the European foot upon the foot.

It strikes the Chinese as very incongruous when they hear that we measure cloth, wood-work, masonry, etc., which they regard as especially matters for the hand, by the foot.

Of the jade tubes above mentioned, there were twelve, and these formed the basis for the measurement of liquids and solids, four thousand years ago. They are mentioned in the oldest Chinese documents with the astrolabe, the cycle of sixty years, and several of the oldest constellations. It is likely that they will be found to be an importation from Babylon, and in that case the Chinese foot is based on a Babylonian measure of a span, and should be nine inches in length.

Canaries: How to Keep and Breed Them.—III.

BY GORDON STABLES.

IN my last article I recommended the reader to get his cages all ready for his coming favorites before buying them, and to get only young, strong, healthy birds, if possible from a prize strain. These questions, then, naturally suggest themselves: Where shall I buy my cages? and where shall I procure my birds? and how much should they cost? Buy your cages, as I have already observed, at a respectable bird-cage maker's, such as will be recommended if you write to this journal for advice in the matter; a good breeding-cage for a single pair will not cost more than from $3.00 to $5.00, furnished. Or you may see cages advertised in any of the cheap "exchange" papers, only be very careful how you deal with strangers.

If you possess what the Scotch call "the bump of gumption," you will be able to buy a very good pair of canaries at a bird-dealers for about five or six dollars; but it would be better to obtain the assistance of some one who knows good birds, and can recommend a particular strain or breed to you. If you want high-class birds, the addresses of successful exhibitors can always be obtained by procuring a prize catalogue of any show of the kind. How are you to get this? Why, write to the secretary and enclose the price of the catalogue with a polite note of request.

Bird-seed ought to be got as pure and good as possible. See that it is free from dust; sift it well, and keep it in clean, dry jars or pickle-bottles. Sea-sand is the best to be put in the bottoms of the cages. The birds ought to have a liberal supply of it, and it should be clean. You can buy it at a grocer's. A little old lime, broken well up, may now and then be

scattered about the bottom of the cage as well as the sand.

Anything of the nature of a narcotic militates against the chances of life in parasites; it is a good plan, therefore, to hang a small bag of camphor in a corner of the cage nigh to the nest. It is as well, too, when the young birds are about half fledged, to give them a clean nest, destroying the lining of the old one, and putting the box aside for disinfection and cleansing.

The eggs take, as I have already told you, thirteen days to hatch; and when the birds are about thirteen days old, the mother thinks she would like to begin to prepare for another family. Give her, therefore, another nest and some nesting material, else it is possible that the hen may attempt to line her nest-pan with the feathers of her progeny. This is what fanciers call plucking the young. If she persists in helping herself to the feathers of her young, they must be placed in a small cage, secured against the breeding-cage in such a way that the parents can get through their heads and necks to feed them. Or the male bird may be turned in for a time with the young; he generally makes a very excellent nurse. But my intelligent young readers will naturally observe, that if the hen has begun to prepare for a new brood, the attendance and supervision of the male will be wanted in the breeding-cage. This is perfectly true, and the difficulty is got over in this way by breeders: they turn the male into the big cage with the hen night and morning for an hour, or less. As soon as the hen has laid her third egg, the male may be retained as nurse only until the day of hatching, by which time the former brood will be able to pick for themselves.

Remember, however, that it is not very often neccessary to remove the young birds from the parent cage until the new brood is actually born, or on the eve of being so. They are then to be turned into a cage by themselves, and the more roomy this is the better, for young birds need exercise.

(To be continued.)

An Arabic Celestial Globe of the Eleventh Century.

IN the philosophical cabinet of the Royal Institute of Florence, many of the instruments of Galileo and other students of astronomy and physics are preserved. Among them is an Arabic celestial globe, of which F. Menssi has published an interesting description. It has not been long in possession of the Institute, and no one suspected its antiquity until recently. The one which is in the Borgian Museum, at Velletri, which was described by Assemani, in 1790, and which dates from the year 1225, has hitherto been regarded as the oldest. There are two others of the same century, one of A.D. 1275, owned by the Royal Asiatic Society of London, and the other of A.D. 1289, in the Mathematical Saloon at Dresden. There are also two, one owned by the Royal Astronomical Society of London, and the other by the National Library of Paris, both of which are without date. Menssi's curiosity was first awakened by observing that the longitude of the stars showed that the globe must have been constructed about the year 1075. On closer examination, he found an Arabic inscription around the Antarctic Circle, which he submitted for translation to the learned Orientalist, Prof. F. Lasinio. He presented a note to the Society, in a meeting which was attended by the Emperor of Brazil, in which he stated that the inscriptions were in Cufir characters, and that the globe "was made by Ibrahim Ihn Said as-Sahli and his son Mohammed; the work was finished in Valenza, in the beginning of the month of Safor, in the year 473 of the Hegira (corresponding to the 22nd of July, 1080)." The diameter of the globe is 209 millimetres (8·23 inches). It is composed of two hemispheres of brass, soldered together, and it gives the arrangement of stars and constellations which was adopted by Ptolemy. Among the Southern constellations, the Cup (Cratern) which should have been placed between the second and third coils of the Hydra, is wanting; all the other constellations

are very well engraved. The positions of 1015 stars are given, and their magnitude is well marked, inasmuch as every point, which is engraved to give the precise position of a star, is the centre of a little circle, which diminishes in diameter from the first to the sixth magnitude. The two circles of the equator and the ecliptic, are divided by means of little lines into 360 degrees, every fifth degree being marked by Cufir numeral figures. The zero of the equator is at its intersection with the ecliptic, in the beginning of the sign Aries. Twelve great circles of declination, lightly engraved, divide the ecliptic into its twelve signs. Forty-seven constellations are represented, 21 of which are in the Northern Hemisphere, 12 in the Zodiac, and 14 in the Southern Hemisphere. A heart-shaped curved line incloses the six stars near Aquilla, which represent upon our celestial globes, the constellation of Antonious. This constellation and that of Berenice's Hair, were introduced by Tycho Brahe, in the 16th century. On this globe, as upon other Arabic globes, the figures face the observer instead of looking towards the centre of the sphere. Therefore the stars which are upon the right side of a constellation on our globes, are on the left on the Arabic globes, and *vice versa.*

The New Postal Notes.

THE new postal notes authorized by the last Congress have now come into use. They are put up in books, each book containing 500 postal note forms, with the address of the post-office printed on each note. The pages of the books are perforated, so that when the notes are torn out stubs remain to show the amounts for which they were issued. A note can be filled out by a postmaster for any amount not exceeding $4.99, at a cost to the sender of three cents for each note. The notes are made payable to "the bearer" and they can be used as fractional currency in any place to which they are sent. The notes are printed on pure linen bank-note paper of the best quality, chemically prepared in such a manner as not to be affected by moisture or exposure to light, while it is sensitive to the action of acids or other liquids often used by forgers. The color of the paper is a pure lemon, and the front surface is printed over with an underlying tint of golden brown. The water-marks in the paper, twisted in the form of a figure 8, have the words "U. S. Postal Note" in duplicate—reading from both left and right. Three printings are required to complete the note. In the underlying tint is a vignette consisting of a classical female head wearing a helmet. Much of the tint is made up of miniature photographic designs, containing the words "United States Postal Note" repeated many hundred times, and engraved so finely that one can read the words with the naked eye, while it would be difficult to make a counterfeit. Winged wheels, with a halo from behind, make up a portion of the tint. The back of the note is elaborate and is printed in a dark green. In the centre is the monogram "U. S." engraved with a geometrical lathe. The monogram is embedded in an intricate cycloidal lace work of white line cutting, the tracings for which were done also with the geometrical lathe.

These postal notes will be an immense convenience in sending small amounts of money, especially where it is desired to send a fractional part of a dollar. To get the money, the note is simply presented at the office on which it is drawn. Before presentation, however, the note must be signed by the person who presents it for payment, on the line where we have signed "*Industrial Publication Co.*" They will be good for three months from the last day of the month in which they are issued. A diagram of the new note is given herewith. A person living in Boston, for instance, and desiring to send any sum below $5, say three dollars and sixty-four cents, to any one in New York, goes to the post-office and deposits the same with a fee of 3 cents. The postmaster will then punch three holes as indicated, to the right of the order, showing the dimes or cents deposited, and dollars if so much, two more holes to the left through month and year.

He will then affix his stamp and signature, and hand over the note without further trouble.

Modern Giants.—Some of the Mighty Men and Women of Late Years.

SAMUEL McDONALD, a Scotchman, nick-named "Big Sam," was six feet ten inches in height. Was footman to Prince of Wales. Died 1802.

Alice Gordon, Essex, England, giantess, seven feet. Died 1737.

Anne Hanen Swan, of Nova Scotia, seven feet.

La Pierre, of Stratgard, in Denmark, was seven feet one inch.

Henry Blacker, seven feet four inches, and most symmetrical. Born at Cuckfield, in Sussex, in 1724. Generally called the "British Giant." Was exhibited in London in 1751.

Howard Hamford, seven feet four inches. Died 1768. Buried in St. Dunstan's churchyard, London.

Louis Frenz, Frenchman, seven feet four inches. His left hand is preserved in the museum of the College of Surgeons, London.

Martin Saleron, a Mexican, seven feet four inches.

Porus, an Indian king, who fought against Alexander near the river Hydaspes, B.C. 327, was seven and a half feet high, with strength in proportion.

Heinrich Osen, born in Norway, seven feet six inches: weight, 300 pounds, or fifteen stone.

Edward Melon, seven feet six inches. Born at Port Leicester, Ireland, 1665, and died 1684, being only nineteen years of age.

James McDonald seven feet six inches. Native of Cork, Ireland. Died 1760.

Robert Hale, seven feet six inches. Born at Somerton, England, in 1820, and often called the "Norfolk Giant." Died 1862.

Francis Sheridan, an Irishman, seven feet eight inches; weight, twenty-two stone; girth of chest, fifty-eight inches. Died 1870.

Bradley, seven feet eight inches at death. Born at Market Wheaton, in Yorkshire, England. His righ hand is preserved in the Museum of the College of Surgeons. 1798–1820.

Joseph Rice, seven feet eight inches. At the age of twenty-six years he was exhibited in London, 1862–5. His hand could span fifteen and a half inches. Born at Ramonchamp, in the Vosges, France, 1840. Was sometimes called Anak.

Cornelius Magrath, seven feet eight inches. He was an orphan and reared by Bishop Berkeley, England. Died at the age of twenty years. 1740–1760.

John Busby, of Darfield, seven feet nine inches. His brother was about the same height.

Joachim Eleozogue, Spanish giant,

seven feet ten inches. Exhibited in London.

Captain Bates, of Kentucky, seven feet eleven and one-half inches. Exhibited in London, 1871, New York, 1880.

Harold Hardradra, Norwegian giant, nearly eight feet.

Gilly, a Swede, eight feet. Exhibited at a show early in the nineteenth century.

William Evans, eight feet at death. Porter to Charles I. Died 1632.

Charlemagne, nearly eight feet. He could squeeze together three horse-shoes at once in his hands.

J. Toller, of Nova Scotia, eight feet. Died 1819.

Maximilian Christopher Miller, eight feet. His hand measured twelve inches and his forefinger was nine inches long. Called the "Saxon Giant." Died in London. 1674–1734.

Chang-woo-goo, of Tychou, Chinese giant eight feet two inches. Exhibited in London and New York, 1866–67 and again in 1880.

J. H. Reichart, of Friedburg, Sweden, eight feet three inches. His father and mother were giants.

Charles O'Brien, of Byrne, Irish giant, eight feet four inches. His skeleton is preserved in the Museum of the College of Surgeons. 1761–1873. Patrick, his brother, was eight feet seven inches.

Loushkin, Russian giant, eight feet seven inches; drum-major of the Imperial Guards.

Maximinus, eight feet six inches. The Roman Emperor, 235–238.

A human skeleton eight feet six inches, is preserved in the museum of Trinity College, Dublin.

What's in a Name?

WHO that has ever examined the blossoms of the potato has not pronounced them beautiful, and many of the new varieties of the potato are very fine. We remember well long years ago, some forty years, when we were importing and testing new species of the potatoes from other States, we carefully planted some eight or ten varieties for a test of their value, and when they were in bloom we gathered many clusters of the new kinds and exhibited them in our stand at the Horticultural Society of Boston, Mass., labelling the entire exhibit as the Blooms of *Solanum Tuberosum*, and as these blossoms were in very handsome clusters our stand attracted quite a crowd, and we heard many young ladies asking their friends:

"Have you seen that stand of new and beautiful flowers exhibited by Mr. Warren?"

For an hour quite a bevy of ladies gathered to see these new flowers of the *Solanum*. After they had been much admired and praised, we took an opportunity to change the label, placing in its stead these words—THE POTATO BLOSSOMS, and we heard often these exclamations—

"Why! is it possible, after all, these were *only* the *Potato* blossoms?"

And thus it is, many of the best blessings of life are greatly undervalued because they are common.—*California Farmer.*

Our Girl's Department.

This department is intended exclusively for "Our Girls," and we hope to make it both interesting and instructive, and to this end we ask our young lady readers to assist by contributions, suggestions, or illustrations. There are thousands of little things that can be, and have been, made and done by young ladies, pertaining to decorative art, needlework, etc., etc., that would be gladly followed but for a want of knowledge on the subject, and we know of no more pleasing task for a lady than that of teaching her younger sisters that which they are anxious to learn, and which may prove of real benefit to them in the future, as well as being useful and interesting for the present. We trust we will have no difficulty in persuading those who have something nice to show or speak of, to make use of this department. Remember, it is open to all, and if you have anything worth knowing suitable for this column, send it along, and we will give it our best attention. Do not be afraid to write because you may fancy your composition is not perfect, or have other scruples of a similar kind. Do the best you can, and leave the rest to the editor of this department, and we are sure you will be pleased with your work.

—Girl in hammock
  Reading book
Catches man
  By hook or crook.
Girl in kitchen
  Scrubbing pan,
Cannot gobble
  Any man.
Ten years later,
  Head in whirl;
Man wishes he'd taken
  Kitchen girl.

— Anger is like rain, it breaks itself upon that on which it falls.—*Pope.*

— If you would not have affliction visit you twice, listen at once to what it teaches.—*Burgh.*

— Fire and sword are but slow engines of destruction in comparison with the babbler.—*Steele.*

— He who receives a good turn should never forget it; he who does one, should never remember it.—*Chanon.*

— The actions of men are like the index of a book; they point out what is most remarkable in them.—*Addison.*

— Ambition often puts men upon doing the meanest offices; so climbing is performed in the same posture with creeping.—*Swift.*

— No man can possibly improve in any company for which he has not respect enough to be under some degree of restraint.—*Chesterfield.*

— An unjust accusation is like a barbed arrow, which must be drawn backward with horrible anguish, or else will be your destruction.—*Taylor.*

— If a man empties his purse into his head, no man can take it away from him. An investment in knowledge always pays the best interest.—*Franklin.*

— Whatever difference there may appear to be in men's fortunes, there is still a certain compensation of good and ill in all that makes them equal.—*Chanon.*

— Of all the vanities and fopperies the vanity of high birth is the greatest. True nobility is derived from virtue, not from birth. Titles, indeed, may be purchased, but virtue is the only coin that makes the bargain valid.—*Burton.*

— Adversity exasperates fools, dejects cowards, draws out the faculties of the wise and industrious, puts the modest to the necessity of trying their skill, awes the opulent, and makes the idle industrious.—*Coleridge.*

— Envy's memory is nothing but a row of hooks to hang up grudges on. Some people's sensibility is a mere bundle of aversions, and you hear them display and parade it, not in recounting the things they are attached to, but in telling you how many things and persons they cannot bear.—*John Foster.*

— Such is the encouragement given to flattery in the present times that it is made to sit in the parlor, while honesty is turned out of doors. Flattery is never so agreeable as to our blind side; commend a fool for his wit or a knave for his honesty, and they will receive you into their bosom.—*Fielding.*

— Dr. H. F. Hamilton says that at least once a day girls should have their halters taken off, the bars let down, and be turned loose like young colts. "Calisthenics may be very genteel, and romping very ungenteel, but one is a shadow, the other the substance of healthful exercise."

— Anxiety is the poison of life, the sure destroyer of health, the parent of many sins and of more miseries. Why then allow it, when we know that all the future is guided by a Father's hand.

— A tidy called a "chair back," can be made by getting one yard of Aida canvas; fringe each end by taking six strands and making into a knot with a crochet needle. The next row must be made by taking three strands from each previous knot and making a knot in the centre of the others. A handsome border must be worked on each side in cross-stitch embroidery. Do not buy your pattern too elaborate, or the work will be tedious. In selecting your pattern be sure to get one requiring bright colors, such as bright blues, reds, bronzes, greens and pretty browns.

— Girl graduates in England wear gowns precisely like those worn by university men, and made by the same tailor. At present they have only donned the B.A., or bachelor of art, robe, which is black and brown, and the B.Sc., or bachelor of science, which is yellow and black, but no doubt in time they will attain to those of higher degrees. The long black silk gowns, which are all of the same pattern, with large cape-like

sleeves gathered into the shoulder, the skirts full and flowing, were worn over ordinary short black dresses, with lace or crepe lisse frills appearing above them at the throat. The ladies, rich in academical honors, wore white gloves, and carried the square white college caps in their hands.

— A San Francisco young woman has started a new business. She goes about from house to house mending jewelry and repairing clocks. When she has to drill a hole in a piece of metal she has drills and a lathe which she works by attaching to a sewing machine. Almost everybody who has jewelry has also a sewing machine. Her trade flourishes. Most ladies have bits of broken jewelry lying about which they do not think it worth while to send to a shop, but which they would gladly have mended should any one come to the house and fix it up at a small price. In the regulating of clocks also she does well. Besides her lathe and drill she has with her, in a neat little box, a full kit of jeweller's tools, a spirit lamp, and blowpipe.

— As a natural sequence to the restraint under which Cuban lovers are held, there are a great many small intrigues and innocent endeavors to circumvent the detectives. There are eloquent glances, signals, fun-talk, and the sly interchange of notes. Then the iron-guarded window, instead of being a protection, becomes a great convenience. It is more than the front gate with us. She knows when he will pass by, and stands inside with a fair hand clasping the bars of her cage and waits for him. They stand there with the iron between them and talk. Every day it is so, and if mamma wishes to stop it she must come and stand in the window also. There are other respects in which the young man has a hard time. He must come every day. He *must*, and she holds him to the strict letter of this law. He is bound to show, by every means in his power, that he holds all other women in contempt and detestation. He must not dance with any other, and had better not be caught holding on to any other window bars in any other street. He tells his near friends about it, and she all hers, and the matter is diligently discussed. If he should fail to come around regularly every day he has to tell a satisfactory story. I have known her to send her brother after him. He takes his revenge after marriage.

— "Do you beat brass?" is the initial catechism of the latest fashionable handicraft in Philadelphia. It is a particular pet with feminine fingers, and requires a thorough and practical knowledge of hammers and tracing tools, brass, and block. A class of ladies, under the patronage of the Scandinavian Thor, have produced some beautiful and lasting work. The instructor teaches them the way of using and holding their tools, and the proper kind of stroke to make upon the steel dies. The method is simple. On a block of wood a brass plate or sheet is fastened. The design is then drawn upon it; the outline hammered by a die, which has a row of dots. Other dies give the groundwork a frosted or mottled appearance. Everything depends on the skill of the workwoman. Really valuable articles in *repousse* brass can be made from a piece of brass costing but a small sum. Card-receivers, plaques, and many other things, can be made. The brass-beating educates the hands and develops the muscles. It is worthy of note how much interest in the mechanical arts is publicly shown, sometimes the hammering of brass is combined with the use of the paint-brush. A brass tray lately seen has a loose spray of purple pansies, apparently flung down carelessly upon it.—*Philadelphia Ledger.*

BEAUTY.—III.

Cosmetics and paints, too, are much used, especially in England. They are as fatal to health and beauty, as they are misleading in effect. The blackened eye may look larger, and the painted lip redder under the uncertain flare of the gas lamp; but, when seen at home in the broad and honest noonday sun, the eye is lustreless. The flaming carmine distorts the mouth, the powdered

skin loses its transparency, and the soft brown hair which formerly enhanced the whiteness of the skin, now appears a lifeless yellow or mahogany red, without light or shade in it. The very men who pretend to admire these artificial dolls, would hesitate to choose their wives from their ranks. Thus once more verifying the old dictum, that "a thing may look well in a shop window, and yet not be adapted for house wear and tear."

There are a few powders that are good for the skin. But many of those purchased at the druggist's contain lead and other poisons. They are done up in elegant wrappers, and look very inviting in the glass cases of the apothecary; but, beware of them, nearly all thicken and roughen the skin.

The Roman ladies used the fine dust of calcined shells for a toilet powder, and the juices of plants to restore their freshness of color. The girls of to-day use to some extent crushed geranium leaves, the juice of strawberries, friction with red flannel, and many other homely substitutes for rouge.

If you will only take plenty of exercise, freely use pure water and soap, and eat wholesome food, avoiding pastry, you will have no need to resort to artificial color.

Violet or baby's powder is one of the best powders as it contains neither lead nor bismuth, and is quite harmless, and looks better than the greasy or shiny appearance that so many have. If used properly it cannot be detected. A layer of powder will prevent freckles and sunburn. It cools feverish skins, and is excellent for prickly heat and summer rashes caused by heat. The skin should be washed before using. Then take a little of the powder and put it in a coarse linen cloth, wash the face quickly with the linen, and the wet powder oozes in its finest state through the cloth, leaving a white deposit when dry. Press the face lightly with a damp cloth, to remove superflous powder.

This mode of using powder, is less easily detected than when it is dusted on dry.

The finest arrowroot scented with orris-root is also good and harmless. The rice powder prepared by Lubin, is very finely ground rice meal, scented with ottar of roses. Of powders made from metallic substances, the best is precipitated carbonate of zinc. It is harmless, and if moderately used, beneficial to the skin. It is a favorite application in skin diseases, and where parts are chafed, or have slight eruptions, its use will be found healing as well as beautifying. With an equal amount of French chalk, it forms a powder highly extolled by some excellent authorities.

If the ambition of beauty would stop here, there would be no complaint to make. But no! a more decided color is wanted—a tint more brilliant than nature herself ever grants. To obtain this, recourse is had to those unwholesome metals, lead and mercury. Those in the form of carbonate of lead, or flake white, and the mercurial white precipitate, are vended for the purpose. They are certain to destroy health, as well as beauty. Moreover, when used, they give a hue so brilliant, that any observer can see at a glance that it is unnatural.

Therefore, from a cosmetic as well as hygienic point of view, they should be abolished, for the perfection of art is to achieve a perfect resemblance to nature at her best, not to surpass her, or fall behind her.

Rose-powders, or flesh colored powders, are prepared from any of the powders mentioned by adding to them a little carmine until the desired tint is obtained.

The most popular and easiest way to imitate the glow of youth on the cheek and lips, is "*to* rouge."

The word rouge in French simply means red, and is applied to many products having this color. That which is put up and sold for the complexion, is generally, and should always be derived from one of two sources: either from cochineal, a small bug found on the leaves of the cactus plant of Brazil, which yields carmine, or from the plant known as "dyer's saffron."

The preparation of rouge is one of the

most delicate operations in practical chemistry, and few beside the French have succeeded in producing a first-class article. A London manufacturer once learned to his cost, that more than mere technical skill was required to produce it. He had tried repeatedly to equal the French article, and failed just as often.

In despair he visited one of the most famous houses in Lyons, and offered the principal thirty thousand francs if he would show him their process. The principal accepted, and conducted the Englishman through the establishment. What was the disappointment of the latter to find the methods in every way identical with his own. He returned home, tried again, and failed. The principal of the Lyons house invited him once more, and put the questions: What was the state of the weather when you made the experiment? "The weather!" replied the Englishman, "the weather! I dont remember. What has that to do with it?" "Everything" replied the principal. "It is only on the fairest days in this favored climate we can make our carmine."

"If that's your secret," said the visitor, "I had better have kept my thirty thousand francs, as it will do me little good in the London fogs."

When the inventive genius has in so many ways prepared materials for whitening, and again for reddening the skin, there still remained the blue lines of the veins, which course beneath the skin, and unless something was found to include these in the "make up," the art was sadly at fault.

It has been done. The elegant world can now provide itself with little jars of Venetian or French chalk, made into a paste with gum water, colored to the proper tint with Prussian blue, and accompanied with little leather pencils, all manufactured on purpose to portray the direction and hue of the veins; this should be done very delicately, and if possible by a cosmetic "artist."

Pallor is associated with sickness and debility, which are not akin to personal beauty. It is just as easy for the skin to be too white, as too red or too brown. Some are troubled with this paleness from childhood, in others it is the result of failing health; in both cases the blood is at fault.

It demands more carbon to form pigment; more iron to build up the system, and color or enrich the blood. Strange as it may seem, it is these familiar and homely substances, charcoal and iron, which the magic wand of nature transforms into delicate dyes, and spreads out on the skin a healthy glow.

It is not enough to take just such things to introduce into the system these indispensable materials in the form best adapted to be readily taken up by the blood. This, indeed, is essential, but beyond this, the surface of the body must be stimulated by regular exercise and friction. To sum up in a few words the prescription for those who, without suffering from any disease, and have a colorless skin, pale lips, and a general want of red blood: A diet, or tonic, or both well supplied with carbon and iron, a lukewarm bath every morning, followed by friction with a rough towel, active exercise in sun and air, and the avoidance of alkaline and astringent soaps and washes.

Beside the friction mentioned as a stimulant to the skin, there is another resource—electricity. Its value as a cosmetic is very great. Any friction that disturbs the electrical condition of the skin, and produces a flush, is good. If the battery is used, brushes made for the purpose are passed rapidly over the surface, causing a not unpleasant tickling sensation, and bringing the blood to the minute vessels with marked force. That method which is called "general electrization," is especially applicable to such cases as described.

Even those faces pitted by the dread disease small-pox, can always be improved, and some greatly so. For this purpose, strong stimulating lotions are employed several times a day, alternated with gentle and long-continued inunction of oil or glycerine. In many cases, by steady perseverance in such applications, very great improvement has resulted.

THE

Young Scientist.

A Practical Journal for Amateurs.

(With which are incorporated "THE TECHNOLOGIST," "THE INDUSTRIAL MONTHLY," and "HOME ARTS.")

PUBLISHED MONTHLY AT $1.00 *PER YEAR.*

EDITORS.

JOHN PHIN. FRED. T. HODGSON.

Published by
THE INDUSTRIAL PUBLICATION CO.,
294 Broadway, New York.

The YOUNG SCIENTIST may now be said to be a fixed fact, or, to use an expression more emphatic than elegant: "It has come to stay." The success of the past years is an evidence of the sagacity of the publishers in seeing and providing for the scientific and mechanical instincts of American youth of both sexes; and, although it has been somewhat difficult to displace, even in a small degree, the baneful and blood-curdling literature, that so plentifully floods the country wherever a youth is to be found, the YOUNG SCIENTIST has forced its way mainly on its own merits into many places where the "blood and thunder" influences once reigned supreme. It is quite true, that without the aid of many of the best families in the land, we should never have been able to hold our own as well as we have done against the fearful odds we battle with; and to those parents and guardians who have stood by us in the fight, we offer our hearty thanks, and trust that our future efforts may be so directed as to still further warrant their substantial appreciation. We will shortly be prepared to furnish full sets of the YOUNG SCIENTIST, beginning with Vol. I, to Vol. VI, making, with the present year, six useful and handsome volumes, admirably suited for holiday gifts either to boys or girls. Next month we shall be in a position to announce when the volumes will be ready, and the price for single ones, or full sets.

As the time is at hand for renewal of subscriptions for the coming year, we feel that we can depend on our friends for a little extra assistance in the way of obtaining new readers, and by so doing, enable us to give them a better and larger paper in the years to come. Every new subscriber added to our already good-sized list, gives us so much more strength, and weakens the common enemy materially. Therefore, we offer no apology whatever for asking our friends to speak a good word for us when opportunity occurs.

To our younger readers we would say, that we are willing to reward their efforts in increasing our circulation by paying them for results in books or otherwise. To those who prefer it, we will send the YOUNG SCIENTIST free, to any one who will send us two new names and two dollars; thus, giving three subscriptions for two dollars.

Where our readers prefer it, we will allow cash commission of twenty cents for every new name obtained. That is, for every new name, remit us eighty cents and retain the twenty for your trouble. This offer, however, will only hold good until January the first 1884.

Boys and girls, to be healthy and happy, must have some useful services to perform. Toil and action are the prices paid for sleep and rest. Laziness begets misery, melancholy, and sickness. Every living thing must work; this is necessary for its existence and enjoyment. The wild beast caged up will roam and wander round its narrow limits, until tired, when it sleeps, and doubtless dreams of the days it was free. Work is a privilege, and one we all should value; therefore we should never refuse to do anything our parents, guardians, or teachers ask of us. They will not ask of us anything unreasonable. Work, boys and girls, fairly and willingly done, will bring you more happiness and genuine healthy joy than

almost anything else in this world. Remember how the little "busy bee gathers honey all the day;" and don't forget what you all have read in the book of Proverbs, where the lazy man is told to "Go to the ant, thou sluggard." To do nothing is to go backwards; something that can not be tolerated in this world. All our wisest and greatest men and women were once industrious and active boys and girls.

Before these lines reach our readers, the public schools throughout the length and breadth of the United States will have been thrown open to receive their precious students, many of whom will become the history makers of the next half century. Every morning now, for many months, thousands of boys and girls will be seen, not as Shakespeare puts it, creeping unwillingly to school, but tripping thither in good heart and with cheerful faces. In Shakespeare's day schools were not what they are now, or he would not have written so disparagingly of the schoolboy. In that age birches were used very extensively, and the pupil's head was cultivated at the expense of their personal comfort. We have improved upon that. We have spoiled the rod and spared the child, and the consequence is that the discipline of benevolence and intelligence has been found to be more effective than the flagellation practiced under the old regime. Our schools and teachers are improving, with occasional lapses, and so are our scholars. These things being so the beginning of the present term was hailed with pleasure, rather than dread and fear.

Athletic Notes.

Base-Ball.

New York vs. Staten Island.—The contest at Staten Island September 5th between the New York professionals and the Staten Island nine proved to be a one-sided contest, in which the professionals won with ease by a score of 10 to 1. O'Neil and Humphries pitched and caught for the New Yorks, and not a run was earned off the former's delivery, the run obtained being scored by errors, the fielding on both sides in the early part of the contest being interfered with by a gale of wind which blew across the field. The pitching and catching of Tyng and Shaw were very good in a majority of the innings. Walden bore off the palm in the field, he accepting eight out of nine chances at second base.

The Metropolitans of New York have played 48 championship games on the Polo Grounds this season, of which they won 30, lost 17, and had one drawn. Of the defeats sustained on the home-field, six were with the St. Louis nine, four with the Eclipse, three with the Athletic, two with the Allegheny, and one each with the Cincinnati and Columbus teams, the Baltimores not scoring a single victory on the Polo Grounds. The Metropolitan victories were six each with the Cincinnati, Columbus and Baltimore teams, five with the Allegheny, four with the Athletics, two with the Eclipse, and one with the St. Louis, their drawn contest being with the Eclipse. The Metropolitans left town for the West Sept. 7.

Swimming and Yachting.

— A sister of Captain Webb is reported by cable to have been found drowned in the river at Ladysmith, Natal. She became insane upon hearing of the death of her brother.

— A movement is on foot to erect a monument to Captain Webb, the swimmer, on the spot on the Severn River where he once saved a life.

— The contest for the amateur swimming championship of England at five hundred yards took place on the evening of Aug. 21 at the Lambeth Baths, London, under the auspices of the North London S. C. First heat: W. R. Itter, Torpedo S. C., first, in 8m. 8s.; W. Henry second, by thirteen yards; A. E. France third. Second heat: E. C. Danels, North London S. C., first; J. Brogan second, by two yards; G. Dunmore third, by a dozen yards. Final heat: Danels first, in 7m. 48¼s.; Itter second, by fifteen yards;

Henry third, by seven yards; Brogan fourth, by six feet.

— The annual swimming contests for the championship of the New York Athletic Club took place on the Harlem River Sept. 8. The one-hundred-yards event was swum across the stream, from the club-house, and was won by H. E. Toussaint in 1m. 35s.; J. B. Moore second, by a yard; H. B. Phinney third, Sidney Green fourth. The half-mile race was down-stream, with the tide, but the contestants had the strong south-west wind against them. C. T. Schlesinger led all the way, and won in 12m. 23¼s.; H. E. Toussaint second, by five yards; Theodore Guierra third, and A. L. Esterbrook fourth.

— Dr. Bryant having shown that the Shadow can beat the Wave of the New York Yacht Club, an effort is being made to match her against the Fanita, owned by George J. Gould, of New York.

— The American Yacht Club have taken a two years' lease of a portion of the apartment-building on the northwest corner of Madison avenue and Twenty-eighth street, New York City, and it is expected that the rooms will be ready for occupancy Oct. 1.

— Hanlan, the champion sculler, will, it is stated, establish a ferry of his own between Toronto and the island on which his hotel is located. This does not lend color to the rumor that he contemplated removing from Canada because his liquor license was revoked.

— The September meeting of the Dorchester (Mass.) Yacht Club was held Friday evening, Sept. 7, at the club-house, at Harrison square. The treasurer reported a balance of $259.18. On account of the closing of the Hotel Pemberton the matter of a supper was laid over.

— The annual regatta of the Oswego Yacht Club was sailed on Lake Ontario Aug. 28. Five yachts competed, and Capt. Cuthbert's Katie Gray, 10 tons, won, defeating the Ella (19 tons), Cricket (10), Laura (11), and Fairwater (12).

— The sloop-yachts Gracie and Fanny, both belonging to the New York Yacht Club, are matched to sail a race off Sandy Hook on Oct. 8. The race will be sailed under the time-allowance given at the last regatta of the N. Y. Y. C.

— The Quincy Yacht Club held their closing regatta for this season over a course off Great Head, Mass., Sept. 8. First and second prizes (cash) were given in each class, and the result was as follows: Second class—J. F. Brown's Niobe first, in 1h. 31m. 5s. actual sailing time and 1h. 3m. 27s. corrected time; J. R. Putnam's David Crockett second, 1h. 31m. and 1h. 4m. 33s. Third class—D. H. Lincoln's Flora Lee first, 1h. 17m. and 51m. 17s.; S. G. King's Samaria second, 1h. 19m. 25s. and 54m. 13s.

— The Cape Ann Yacht Club sailed their open regatta, for small boats, postponed from the preceding day, at Gloucester, Mass., on Sept. 1. A fairly good breeze came from the northeast, and the weather was bright and bracing on the water. There were eight starters in the first class, for yachts over 20 ft.; fourteen in the second, over 15 ft.; and six in the third, under 15 ft. Three cash prizes were offered in each class, which were won as follows: First class, 12 miles—Cunningham's Kittiwake first, in 3h. 48m. 9s. actual and 3h. 2m. 39s. corrected time; McKenzie's Venus second, 3h. 49m. 55s. and 3h. 9m. 23s.; Pigeon's Judith third, 4h. 2m. 48s. and 3h. 21m. 10s. Second class, 6 miles—Griffin's Sassacus first, 1h. 25m. 25s. and 58m. 34s.; Tucker's Sunbeam second, 1h. 33m. 24s. and 1h. 5m. 8s.; Holder's Helen third, 1h. 30m. 37s. and 1h. 6m. 10s. Third class, 6 miles—Williams' Marchioness first, 1h. 45m. and 1h. 13m. 54s.; Bickford's Tit second, 1h. 56m. 57s. and 1h. 24m. 3s. Judges—H. F. Sanford, George H. Oakes and G. H. Blatchford.

— The annual regatta of the Union Boat Club was held on the Harlem River on Saturday, Sept. 8. The weather was cloudy and threatening, and a stiff breeze from the southwest roughened the water considerably. The distance rowed in all the races was one mile, straightaway, and the results were as follows:

Pair-oared gigs.—S. Van Zandt, O. J.

Stephens, J. J. McGeer (coxswain), first, in 8m. 14s.; O. Berger, V. R. Roby, J. T. Harden (coxswain), second by several open lengths; D. W. Edwards, A. Waengler, L. Walter (coxswain), beaten off.

Senior single-sculls.—J. R. Pettit first, in 8m. 55s.; Max B. Kaesche second, by more than a length; P. J. Engel and James Gallagher did not finish. The winner was in front from the start.

Junior single-sculls.—L. Walter first, in 8m. 23s.; Floyd Grant second; W. H. Connell, 0; W. D. Kelley, 0; T. A. Fitzsimmons, 0. At the first attempt a foul occurred between Kelley and Grant, causing a fresh start. A steam-launch interfered with Connell, and Kelley met with a mishap by the breaking of his footstrap.

Four-oared gigs.—J. R. Pettit (bow), O. J. Stephens, W. D. Kelley, S. Van Zandt (stroke), J. J. McGeer (coxswain), first; P. J. Engel (bow), William Schulet, Oscar Berger, Max B. Kaesche (stroke), A. J. Maehler (coxswain), second.

Six-oared gigs.—Bachelors: V. R. Roby (bow), William Schuler, O. J. Stephens, William Lalor, L. Walter, Max B. Kaesche (stroke), John T. Harden (coxswain), first, in 7m. 6s.; Benedicts: P. J. Engel (bow), F. Grant, J. W. Goodsill, Jas. McCartney, Oscar Berger, A. Schneider (stroke), A. J. Maehler (coxswain), second, by two lengths.

Eight-oared shells.—James Gallagher (bow), Joseph Halk, L. Shaffner, T. A. Fitzsimmons, J. R. Pettit, V. R. Roby, William Schuler, Max B. Kaesche (stroke), John T. Harden (coxswain), first, in 6m. 32s.; E. J. Connell (bow), D. McGin, J. C. Martin, G. W. Koehler, F. Grant, L. Walter, Oscar Berger, Wm. Lalor (stroke), D. W. Edwards (coxswain), second, by a few feet.

Odd Notes.

— The largest black bass known to have been caught in Greenwood Lake is stated to have been landed a few days ago by Andrew Dickinson. It weighed a little more than eight pounds.

— About two thousand persons were at the Nantasket Skating-rink, Mass., Sept. 1, to witness a game of roller-polo between the Boston and Nantasket Clubs. The latter team won the first goal after playing seven minutes, and, as the half-hour limit expired before another was gained, the Nantaskets carried the day.

— The thirtieth anniversary of the birth of the Pottsville Fishing Party, a social organization composed of prominent men, was on Aug. 30 appropriately celebrated at the People's Railway Park, Pottsville, Pa.

— At a meeting on Sept. 6 of the committee appointed by the National Rod and Reel Association to make arrangements for the tournament to be held Oct. 16 and 17, different committees were appointed and an amateur fisherman was defined to be one "who has never fished for a living, has never been a guide, and has never been employed in the sale or manufacture of fishing tackle."

— A meeting of the National Rifle Association was held Sept. 4, at which it was announced that sufficient funds had already been guaranteed to enable an English team to come to this country next Summer. A committee of five will be appointed by the N. R. A. to prepare for the match.

— The first annual picnic of the Boston (Mass.) Homing Pigeon Club was held Sept. 4. The entertainment consisted of dancing and the liberation of several coops of thoroughbred birds which were on exhibition. Sixteen birds were sent to Cambridgeport, eight to Dedham, fifteen to Lowell, seven to Stoneham, twelve to Waltham, twenty to City Point, fifteen to South Boston, and nine to Jamaica Plain—102 in all. The fourteen birds that made the 800 miles' journey from Canada were on exhibition and attracted much attention.

Correspondence.

Ed. Young Scientist—Dear Sir: I would beg leave to call your attention to the fact that here on the Boise River is a place where flowers in abundance furnish food for an unlimited number of bees. I have been up on the South Fork of the Boise River, where no one yet has ven-

tured to settle, and found in May, June and July the greatest abundance of honey flowers growing in vast quantities. The main flower belongs to the *Syringa Philadelphus*, if I am right, a single white flower growing on a shrub from six to twelve feet high, and covered with these white flowers in great beautiful masses, making the air redolent with the smell of honey. It only requires a small capital for the cost of bringing the bees here, and in these mountains there is only the bears and the winter to disturb you. The description of the unsettled portion would furnish enough interesting letters to keep you in correspondence the whole season. But if you are not interested, if you will hand this to some one likely to be interested enough to try the experiment I shall be satisfied.

Yours very truly,

JAMES M. HAMILTON, Ass't Engineer.

Boise City, Idaho, Sept. 7th, 1883.

Astronomy for Amateurs.—October.

BY BERLIN H. WRIGHT.

THE PLANETS.—OCTOBER, 1883.

(All Computations are for the Latitude and Meridian of New York City.)

Mercury may be seen in the latter part of October, being a morning star (at greatest western elongation), and brightest Oct. 22d to 25th. He rises as follows:

Oct. 20th—4 47 morn., 1h. 30m. before sunrise.
" 25th—4 55 " 1h. 28m. " "
" 30th—5 17 " 1h. 12m. " "

and about 12° north of the sunrise point, and 2° south of east point.

He will be moving eastward past the stars of the constellation Virgo, being in conjunction with the 3d mag. star *Gamma* Virginis on the 20th, and only about 1° south of that star. On the 27th he will be 5° 20′ north of the bright star *Spica* Virginis, and on the 29th 3° north of the Moon.

Venus, although an evening star, will scarcely become visible this month, setting, as she does, on the 30th at 5.24 eve.

Mars is still a late riser. He is in the cluster of small stars called Præsepe in Cancer on the 24th; in conjunction with Jupiter on the 19th, being only 1° north of the giant planet, and 7° north of the Moon on the 23d. Mars rises as follows:

October 10th—11 25 evening.
" 20th—11 10 "
" 30th—10 54 "

Jupiter is passed by Mars on the 19th, previous to which time he was to the east of Mars. He rises as follows:

October 10th—11 45 evening.
" 20th—11 11 "
" 30th—10 36 "

The Moon passes 5° south of Jupiter on the 23d, and he reaches his western quadrature on the 27th.

Saturn is retrograding or moving westward past the stars near the Hyades, and rising at a very convenient hour, as follows:

October 10th—8 3 evening.
" 20th—7 23 "
" 30th—6 41 "

Neptune is now nearly at apposition to the Sun, at which time he is brightest, but even under these favorable circumstances a good instrument and a precise knowledge of his location is necessary to find him. He passes the Meridian as follows:

Oct. 10th—2 0 morning in R.A. 3h. 14m. + 16° 9′
" 20th—1 20 " " 3h. 13m. + 16° 5′
" 30th—0 40 " " 3h. 12m. + 16° 1′

He may be found 8° a trifle west of south of the Pleiades.

ECLIPSES.

Two of the four eclipses of this year occur in the month of October. The first is a Partial Eclipse of the Moon, October 15-16, visible throughout this country. See the following table, where the evening time occurs on the 15th and the morning on the 16th.

TABLE OF PARTIAL ECLIPSE OF THE MOON, OCTOBER 15-16, 1883.

	Eclipse Begins.		*Middle of Eclipse.*		*Eclipse Ends.*

St. Paul, Minn.	11	46 e.	0	42 m.	1	38 m.
Washington, D. C.	0	50 m.	1	46 m	2	42 m.

Size of Eclipse = 3.36 Digits.

The second is an Annular Eclipse of the Sun, October 30th, visible as a partial eclipse on the southern limb of the Sun in the Pacific States;

the Sun setting with the eclipse of about 8 digits still upon it. At San Francisco the eclipse begins at 3h. 40m. in the afternoon. Visible nearly as far east as the Black Hills in Wyoming Territory, and Denver, Colorado, where the eclipse begins just after sunset. At Santa Fe, N. M., it will be a mere contact of limbs at sunset. At Helena, Mont., the eclipse begins at 4.40 P.M. At Walla Walla the beginning occurs at 3h. 48m., and the middle at sunset. At Portland, Oregon, begins at 3h. 38m., and the middle at sunset.

EPHEMERIDES OF THE PRINCIPAL STARS AND CLUSTERS, OCT. 21ST, 1883.

	H.	M.	
Alpha Andromeda (Alpheratz) in meridian	10	2	eve.
Omicron Ceti (Mira) variable, in meridian	0	17	mor.
Beta Persei (Algol) variable, in meridian	1	3	"
Eta Tauri ("Seven Stars" or Pleiades) rises	6	12	eve.
Alpha Tauri (Aldebaran) rises	7	31	"
Alpha Auriga (Capella) in merid.	3	11	mor.
Beta Orionis (Rigel) rises	9	38	eve.
Alpha Orionis (Betelguese) rises	9	23	"
Alpha Canis Majoris (Sirius or Dog Star) rises	11	39	"
Alpha Canis Minoris (Procyon) rises	11	14	"
Alpha Leonis (Regulus) rises	1	21	mor.
Alpha Virginis (Spica) rises	5	58	"
Alpha Bootis (Arcturus) rises	5	1	"
Alpha Scorpionis (Antares) sets	6	43	eve.
Alpha Lyrae (Vega) sets	1	30	mor.
Alpha Aquillae (Altair) sets	0	18	"
Alpha Cygni (Deneb) "	4	36	"
Alpha Pisces Australis (Fomalhaut) sets	0	54	"

De Land, Florida.

Human Hair Under the Microscope.

E. B. Tylor, in *Nature*, says that the microscopic examination of the cross section of a single human hair is sufficient to determine to which one of the race divisions of humanity the wearer belongs. If examined microscopically by Pruner's method, it shows circular, or oval, or reniform. Its follicle curvature may be estimated by the average diameter of the curls as proposed by Moseley. Its coloring matter may be estimated by Sorby's method. There has been even a systematic classification of man published by Dr. W. Muller, of the Novara expedition, which is primarily arranged according to hair, in straight-haired races, curly-haired races, etc., with a secondary division according to language.

Telegraphy in Rhyme.

A - — "A" 's a dot and then a dash;
B — - - - "B," dash, three dots like a flash;
C - -   - "C," two dots, a space, a dot;
D — - - Dash, two dots, and "D" you've got;
E - "E" is but a period—
Readers, are you wear-i-ed?

F - — - "F" is made thus—dot, dash, dot;
G — — - Dash, dash, dot, to "G" allot;
H - - - - Four dots, "H"—how's that for high?
I - - Two dots "I" will satisfy;
J — - — - "J," dash, dot, dash, dot, you sound;
K — - — Dash, dot, dash for "K" you've found.

L —— "L" 's long dash, so rest your hands!
M — — Next two dashes "M" demands;
N — - "N" 's dash, dot, made closely—see?
O -   - "O" 's a dot, space, dot—O, me!
P - - - - - Five dots next for "P" suffice;
Q - - — - "Q," two dots, dash, dot—how nice!

R -   - - Dot, space, two dots for "R" next;
S - - - "S," three dots—now watch my text;
T — "T" 's short dash, half size of "L";
U - - — "U" 's two dots and dash—that's well!
V - - - — "V" is three dots, dash—art tired?
W - — — "W" 's dot, two dashes wired.

X - — - - Dot, dash, two dots, "X" you'll find;
Y - -   - - "Y," two dots, space, two dots, mind!
Z - - -   - Three dots, space and dot are "Z";
& -   - - - "&" is vice versa—see!

The Origin of Lightning.

In explaining satisfactorily the phenomenon of lightning, a difficulty is encountered in accounting for the enormous electric tensions which are necessary to explain the great length of the spark often observed The theory is advanced by A. Fick that the high tensions are produced by the sudden concentration of electricity already existing in a free state. This concentration is caused by the formation of large drops of rain from the small vesicles of moisture existing in the clouds, by which the surface upon which the electricity exists is greatly diminished. The sudden formation of drops of water from the mass of aqueous vapor may be due to the advance of cold-air currents. Mr. Fick endeavors to answer two objections which may be urged against this theory: 1. That in every rain storm lightning ought to be seen. 2. That it ought to rain whenever it lightnings. To the first objection he replies that the drops may be formed gradually, and not suddenly, in which case the tensions would be dissipated gradually; and to the second, that drops are always formed in connection with lightning, but that in falling to the earth they sometimes encounter a layer of dry air, and are absorbed in their passage.

Ye Ancient Dude.—The Æsthetic Wonder of the Eighteenth Century.

A new kind of dandy appeared in 1770. It was customary in the last century for young men of rank to finish their education by making the grand tour of the Continent, and a number of them at the close of their travels formed a club in St. James Street, which they called the Savoir Vivre Club. They had periodical dinners, at which they introduced the now familiar, but then unusual dish, macaroni, and, first applied to members only, this strange name was afterwards used to describe all such exquisites as they were.

They were the objects of as much ridicule as the modern "dude." Wearing their hair drawn high above the scalp in the shape of a bee hive, with long curls at the side and an enormous chignon, they crowned this superstructure with an exceedingly small cocked hat. Their coats, waistcoats, and breeches were scant, the latter being of striped silk, with bunches of ribbon at the knee. They carried long canes, decorated with silk tassels, and wore two watches, with large bunches of seals hanging from them. Around their necks they had white ties, fastened under their chins with an immense bow. Their calves were displayed in white stockings, and their feet encased in small shoes with diamond buckles. The ladies vied with the men in the extravagance of their costume, and likewise wore their hair in great puffs, which seemed to overbalance their bodies.—*Boston Herald.*

Scientific News.

—The whistle of a locomotive is heard 3,300 yards, the noise of a train 2,800 yards, the report of a musket and the bark of a dog 1,800 yards, the roll of a drum 1,600 yards, the croak of a frog 900 yards, and a cricket's chirp 800 yards.

—It has been observed that "right-handedness" extends far down in the scale of creation. Parrots take hold of their food in their right foot by preference, and insects, like wasps, beetles and spiders, use the right anterior foot most frequently.

—Deaf mutes are taught to speak and comprehend by watching the movements of the lips. According to the *Photographic News*, M. Wanerke has photographed the face of a man in which these movements were perfectly defined, so as to have the exact form corresponding to each sound. By means of these photographs inexperienced persons have been enabled to recognize the different articulations.

—The following is the estimated railway mileage of the world, January 1st, 1883; United States, 113,000 miles; Europe, 109,000; Asia, 8,000; South America, 7,000; Canada, 8,500; Australia, 3,200; Africa, 2,200; Mexico, 2,100. Grand total, 253,000 miles. These figures, however, are not claimed to be exact, being based upon the latest available returns, to which the probable increase since such period has been added.

—Professor H. G. Williams has been engaged in the study of the Devonian section of Western New York, under the direction of the Paleontologic Branch of the United States Geographical Survey. He reports good progress. Mr. L. C. Wooster was engaged during July in the collection and study of Potsdam fossils. He has been quite successful in these collections, and has already forwarded eight boxes to the National Museum here.

—The name of Roebling, the man who built the Brooklyn bridge, which has just been completed at a cost of more than $20,000,000, is put as architect on a wooden bridge across Little Hickman creek, in Jessamine county, Ky., dated 1855. The father was killed in the construction of the Brooklyn bridge and the son so wounded that he was confined to a room from which he watched the construction with a telescope, while his wife was the bearer of his orders.

—An interesting experiment in heliography, or signalling by sunshine, was successfully made in Egypt during the recent campaign. Colonel Keyser ascended one of the pyramids near Cairo, and by means of a heliographic mirror reflected a ray of sunlight to Alexandria, 120 miles away. At that great distance the signals, appearing like pin points of brightness, were easily ascertained to be a message from Sir Garnet Wolseley to the Khedive.

—The utilization of slag waste is fast assuming considerable economical importance. The manufacture of bricks from granulated blast-furnace slags will soon be begun in Germany. The slags are run into water, and the grit thus obtained is mixed up with lime, concrete, or plaster-of-Paris, and formed into bricks, which are dried for a month. They possess greater solidity than common brick, and seem to resist a much greater pressure.

—Prof. Sir W. Thomson, in his new treatise on natural philosophy, is led by a consideration of the necessary order of the cooling and consolidation of the earth to infer that the interior of our globe is not, as commonly supposed, all liquid, with a thin solid crust of from 30 to 100 miles thick, but that it is on the whole more rigid than a continuous solid globe of glass of the same diameter, and probably more rigid than such a globe of steel.

—It seems to me I can best lay this ghost of our animal origin by drawing attention to the fact that the swinging of any part that is sufficiently free may be used for steadying the body in walking. In man the arms are used, because most movable; but in lower animals the head is most often used. The domestic fowl moves the head back and forth alternately with the move-

ment of the legs; the horse moves the head up and down; the cow moves the nose back and forth. Are these movements ghosts of a former real walking with the head?—*Joseph Le Conte, in Science.*

—A correspondent in writing from New York says, judging from present indications, gilding on plaster for ornamenting mirror frames will soon be a fashion of the past. The utmost ingenuity is exercised in framing, and sometimes with charming effect. A mirror lately seen was framed in old tapestry of a dull gold ground, on which, on either side, are pictured mediæval saints with golden nimbus and robes of dull red and blue. Across the upper and lower parts of the frame are wrought festoons of flowers. A second mirror shows an oaken frame with a band of dull gold, on which are applied garlands of carved flowers.

Practical Hints.

—Wire rope must not be coiled or uncoiled like hemp rope. When mounted on a reel the latter should be turned on a spindle to pay off the rope. When forwarded in a coil without reel, roll it over the ground like a wheel and run off the rope in that way. All untwisting must be avoided.

—For poison ivy, bathe the parts in a decoction of hemlock boughs or of oak leaves, or with a teaspoonful of copperas (sulphate of iron) in a small teacupful of boiling water; or rub wet salt on the affected parts. If the blisters are broken, one application of nitre will be sufficient.

—Fat is said by Dr. F. L. Oswald to be the best lung food, and among all fat-containing substances sweet cream is the best, salt pork the least nutritious. Consumptives should avoid all scorbutific articles of diet; salt meat, pickles, cheese, pungent spices, made dishes, and all intoxicating drinks.

—A new invisible ink has been introduced by Dr. Widemann. It is made by intimately mixing linseed oil 1 part, water of ammonia 20 parts, and water 100 parts. The mixture must be agitated each time the pen is dipped into it, as a little of the oil may separate and float on the surface, from which, if taken up by the pen, a stain would be left upon the paper. To make the writing appear all that is needed is to dip the manuscript in water; when the paper dries the writing will vanish.

—A German journal gives the following leather polish:—Mix 200 parts of shellac with 1 000 of spirits—95 per cent.—in a well-stoppered bottle. Keep in a warm place for two or three days, shaking frequently. Separately dissolve twenty-five parts of Marseilles soap in 375 of warmed spirits—25 per cent.—and to the solution add forty of glycerine. Shake well and mix with the shellac solution. To the mixture add five parts of nigrossin dissolved in 125 of spirits. Well close the vessel and shake energetically, and then leave the mixture in a warm place for a fortnight.

—A very good fly-paper may be made after the following receipt: Gum turpentine, 10 parts; yellow wax, 4 parts; lard, 14 parts. Melt, strain through a muslin cloth, and after solidification add as much oil (say linseed) as may be necessary to give the proper consistency on the paper. When prepared lay two papers together, face to face. If the above proportions do not give just the results desired, they should be varied by taking different quantities of the ingredients until a satisfactory material is made.

—Soapsuds will not chap or injure the hands even if kept a long time in it, if on taking them from the suds they are thoroughly sponged, or dipped in lemon juice or vinegar. The acid destroys the corrosive effects of the alkali and makes the hands soft and white. Indian meal and lemon juice, used when washing the hands when roughed by cold or hard work, will heal and soften them. Vinegar will answer if lemons are not easily obtained. Rub the hands in this, then wash thoroughly, and if you have it, after drying put on a few drops of glycerine. Those who suffer from chapped hands in the winter will find this comforting, and will make sewing much easier.

Notes and Queries.

In continuing this department, which has been found of so much value, we would remind our readers who wish for information on any of the arts and sciences, that they are cordially invited to make their wants known through this column, and those of them who can furnish accurate answers to questions asked are requested to send in replies. Doubtless many of our subscribers may know of methods, processes, or devices that may be better or more suitable for the particular case in question than anything generally known, and it is this reason that induces us to keep this department open for a medium, where an interchange of ideas and practices may be made to the advantage of all our readers. Correspondents will please send their full address when forwarding their communications—either questions or answers—not for publication, unless expressly so stated, but so that we may know where to find the writer if desirable. Communications should be sent in on or before the first of each month previous to publication, to insure insertion in next issue.

Answers.

115. In answer to Katie B. (August YOUNG SCIENTIST) as to impression of leaves, I would recommend the following: Bichromate of potash, 10 grs.; sulphate of copper, 20 grs.; distilled water, 1 oz. Wash a piece of letter paper on one side with this solution, and let it dry in the dark. Procure a pane of window glass free from specks, a piece of thin board the size of the glass; lay several pieces of paper and a piece of black cloth the size of the glass and board, placing the paper next to the board, the cloth on the paper, and on the cloth the sensitive paper (this should always be kept in the dark until you are ready to use it), and on this place the leaf; over the whole place the glass; fasten with spring clothes pins, and expose to clear sunshine a few minutes; remove, and wash the picture in the dark with a solution of nitrate of silver of moderate strength. Engravings may also be copied by this method.—CAMERA, JR.

116. To gild on glass, first clean and dry the glass thoroughly, then lay out the lines for letters with a piece of hard scented soap, then paint the letters on the *right* side of the glass with lampblack mixed with oil, in order to *form a guide for the work,* then on the inside lay on a coat of size, using a camel's-hair brush, covering the whole of the letters; next lay on the gold leaf with a tip, until every part of the letters is covered well. Let the leaf remain until the size is dry, when you will find that the letters on the front side can be easily seen and traced. This is done with quick drying black, mixed with a little varnish. Paint over the whole directly over the gold; allow it to dry; then wipe off with soap and water the lampblack letters from the front side; with pure cold water and a clean sponge, wash the superfluous gold leaf and size from the back, and you will have a splendid gold letter on the glass; next, shade your letter to suit the taste, always remembering to shade to the edge of the gold, for then you have only *one* edge to make straight. The other edge may be left rough, and when dry may be straightened by scraping with a knife.

In making scrolls, eagles, etc., on glass, some painters put on the outlines and shades first, and then lay the gold leaf over all; another good way is to scratch the shades on to the gold leaf after it is dry, and put the colors on the back of the gold. Silver leaf may be used in the same manner as gold, but it will not wear as well. A very pretty letter may be made by incorporating silver with gold: take paper and cut any fancy design to fit the parts of the letter; stick it on the size before laying the leaf, allowing it to dry, and wash off as before; then with a penknife raise the paper figure, and the exact shape or form of the figure will be found cut out of the the gold letter; clean off nicely, apply more size, and lay *silver* leaf to cover the vacant spots; wash off when dry, and a very handsome letter will be the result. Colors may be used instead of silver, if desired, or a silver letter edged or "cut up" with gold, will look well.—SNOB.

117. SADIE.—Drop your shells into hot water, and gradually increase its temperature to boiling point. When they are quite dry rub them over with a little olive oil. Sea-shells should be steeped in water till the salt is extracted. Coral is bleached by being boiled in water to which oxalic acid has been added.

118. In strict architectural parlance—yes; in ordinary language—no. The house should be larger than the villa, and the villa than the cottage; but in almost every suburban street where the houses are identical in size, plan, and construction, you will find one man calling his dwelling a "house," his next door neighbor rejoicing in a "villa," while his friend to the left is satisfied with a "cottage," and his next-door-but-one proclaims itself to be a "residence."

119. Make a box with the top, bottom and sides of thin wood, and the ends 1½ inch beech, form it the same length as the width of the window in which it is to be placed. The box should be three or 4 inches deep, and 6 or 7 inches wide. In the top of the box, which acts as a sounding board, make three circular holes about 2 inches in diameter, and an equal distance apart. Glue across the sounding board, about 2½ inches from each end, two pieces of hard wood ¼ inch thick, and ½ inch high, to serve as bridges. You must now procure from any musical instrument maker twelve steel pegs similar to those of a pianoforte, and twelve small brass pins. Insert them in the following manner into the beech: first commence with a brass pin, then insert a steel peg, and so on, placing them alternately ½ inch apart to the number of twelve. Now for the other end, which you must commence with a steel peg, exactly opposite the brass pin at the other end, then a brass pin, and so on, alternately to the number of twelve; by this arrangement you have a steel peg and a brass pin always opposite each other, which is done so that the pressure of the strings on the instrument shall be uniform. Now string the instrument with twelve first violin strings, making a loop at one end of each string, which put over the brass pins, and wind the other ends round the opposite steel pegs. Tune them in unison, but do not draw them tight To increase the current of air, a thin board may be placed about 2 inches above the strings, supported at each end by two pieces of wood. Place the instrument in a partly opened window, and to increase the draft open the opposite door. See back numbers of the YOUNG SCIENTIST for further information.—MUSIC.

120. JUMBO.—Is the density of the matter of which any body is composed, compared with the density of another body assumed as the standard, or 1,000. This standard is pure distilled water for liquids and solids, and atmospheric air for gaseous bodies and vapors. Thus as gold is 19 and silver ten times heavier than water, those numbers, 19 and 10, are said to represent the specific gravity of gold and silver. The heaviest known substance is iridium, used for pointing gold pens; its specific gravity is 23. The lightest of all liquids has a specific gravity of 0.6, it is called chimogene, and is made from petroleum; it is exceedingly volatile and combustible, being, in fact, a liquefied gas. Carbonic acid gas or choke damp is 500 times lighter than water, common air 800, street gas about 2,000, and pure hydrogen, the lightest of all substances, 12.000 times. The heaviest substance has thus 23 + 12,000, or more than a quarter of a million times more weight than an equal bulk of the lightest; and the substance of which comets consists is supposed by astronomers to be even several thousand times lighter than hydrogen gas.—KINO.

121. ANTIQUARIAN.—The oldest specimen of pure glass bearing anything like a date is a little moulded lion's head, bearing the name of an Egyptian king of the eleventh dynasty, in the Slade collection at the British Museum. That is to say, at the period which may be moderately placed at more than 2,000 years B. C., glass was not only made, but made with a skill which shows that the art was nothing new. The invention of glazing pottery with a film or varnish of glass is so old that among the fragments which bear inscriptions of the early Egyptian monarchy are heads possibly of the first dynasty. Of later glass there are numerous examples, such as a bead found at Thebes, which has the name of Queen Hatasoo, or Hashep, of the eighteenth dynasty. Of the same period are vases and goblets and many fragments. It cannot be doubted that the story prepared by Pliny, which assigns the credit of the invention to the Phœnicians, is so far true that these adventurous merchants brought specimens to other countries from Egypt. Dr. Schliemann found disks of glass in the excavations at Mycenæ, though Homer does not mention it as a substance known to him. That the modern art of the glass-blower was known long before is certain from representations among the pictures on the walls of a tomb at Beni Hassan, of the the twelfth Egyptian dynasty; but a much older picture, which probably represented the same manufacture, is among the half-obliterated scenes in a chamber of the tomb of Thy at Sakkara, and dates from the time of the fifth dynasty, a time so remote that it is not possible, in spite of the assiduous researches of many Egyptologers, to give it a date in years.—KERAMIC.

122.—To KATIE B.—The writer of the lines you quote was Charles Swain.—PHILIP.

Queries.

123. Having a lot of fancy chickens, and wishing to keep them all winter, I am desirous of having a warm house built for the purpose. Do you think a house built of gravel or concrete would be warm enough? and if so, could you give me a few hints regarding the materials to be

employed, and the manner of putting the house up, as I wish to do all the work on it myself, not being rich enough to employ a regular mechanic?—NEW HAMPSHIRE BOY.

124. Ought a clever boy, 16 years of age, be able to construct a cheap and comparatively correct barometer? If so, how ought he to go about the work.—WEATHERWISE.

125. I am taking lessons on the violin, and would like to know something about the instrument I am learning to play on, and also what are the peculiarities that make what are called the "good points" of a violin?—F. K. DANBURY.

126. How can I bore or drill a hole through a glass plate?—PUZZLED.

127. I have a pet dog—a little English terrier—also a canary; both are ill, and seem pining away. I don't know what is the matter with them; can any reader suggest anything that I can do for them?—DAISY, N. J.

128. If some one will answer the following questions I will feel obliged: (1) What is good for removing dandruff from the scalp? (2) How may I remove grease spots from a Cashmere garment? (3) What will remove ink stains from cloth?—DAISY, N. J.

129. (1) When and where were the first bicycles and velocipedes made? (2) Who first adopted the india-rubber tires? (3) Does a plated machine keep clean easier than a polished one? (4) How can I keep the spout of my oil can from getting choked up?—CYCLIST, Orange, N. J.

130. I have seen somewhere an account of what a horse can do in a given time. I would like to see the item referred to in print in the YOUNG SCIENTIST; if any fellow reader who may have the item in his possession, will forward it to you for publication, and if you will be kind enough to publish it. I am sure it will be interesting to many of your readers, besides a—FARMER BOY N. Y.

131. How are cameos made, and what do portraits in cameo cost.—LITTLE MAIDEN, Mich.

132. C. H. P., R. S., L. V. M., and several others would like to have designs of monograms in rustic style of the above letters. We have also a number of other requests for monograms in various styles and combination. We will publish a whole page of monograms in our January issue, in which we will try and illustrate most of those asked for. In the mean time, we hope those of our friends who are able to design will send in such combinations as they may see fit.—[ED.]

Market Report.

Retail Prices.

IMPORTED CAGE BIRDS.

Canaries, *Belgian*, per pair	$6.00 to 15.00
" *French*, per pair	6.00 to 15.00
" *German, Hartz Mts.*, each	2.50 to 10.00
Gold Finches, each	1.50
Gold Finch (mules), each	2.50 to 5.00
Bull Finches, not trained, each	2.50
Bull Finches, trained to sing two tunes, each	10.00 to 40.00
African Finches, per pair	2.50 to 5.00
Chaffinches each	1.50
Talking Mino or Mina	10 00 to 25.00
Linnets, each	1.50 to 2.00
Linnets (mules), each	2.50 to 5.00
Green Linnets, each	1.50
Java Sparrows (blue), each	1.50
Java Sparrows (white), per pair	6.00 to 8.00
English Sparrows, per pair	1.00
Siskins, each	1.00
Gray Cardinal, each	4.00 to 5.00
Nightingales, each	8.00 to 25.00
Japanese Nightingales, each	5.00 to 10.00
Thrushes, each	5.00 to 7.00
Skylarks, each	5.00
Troopials, each	7.00 to 12.00
European blackbirds, each	5.00 to 7.00
Black-caps, each	4.00
Starlings, each	4.00 to 6.00

PARROTS.

Gray Parrot	10.00 to 15.00
Single Yellow-Head Parrot	8.00 to 12.00
Double Yellow-Head Parrot	10.00 to 15 00
West Indian "	4.00 to 5.00
Cockatoo (white)	18.00
Australian Shell Paraquets, per pair	6.00
"Love Birds," African Paraquets, per pair	6.00
West Indian Paraquets, per pair	3.00 to 5.00

All birds that are accomplished singers or talkers bring high and "fancy" prices. Parrots are rated by the number of words, sentences, and tunes they have learned.

AMERICAN CAGE BIRDS.

Canaries, each	2.50
Mocking Birds, females, each	1.00
" " singers	12.00 to 25.00
Robins	2.50 to 5.00
Blue Birds ("Blue Robins") each	1.50
Indigo Birds, each	1.00
Nonpariel, each	1.50 to 2.00
Virginia Cardinal, each	2.50 to 3.00
Bobolinks, each	1.50 to 2.00
Yellow Birds, each	1.50 to 2.00

Prices Paid by Dealers.

Robins, per hundred	12.00
Blue Robins (Blue-Birds), per pair	0.35
Indigo Birds, each	0.50
Bobolinks, per dozen	3.00
Yellow-Birds, per hundred	12.00
Orioles, per hundred	25.00 to 35.00
Virginia Cardinals (Red-Birds), each	0.75 to 1.00
Nonpareils, each	0.75
Blue-Jays, each	0.35
Scarlet Tanagers, each	1.00
Red-Winged Starlings, or Black-Birds, each	0.25
Woodpeckers ("High-Holers"), each	1.00
Partridges, each	1.50
Cranes, each (according to variety)	10.00 to 20.00
Wood-Ducks, per pair	2.50
Wild Bronze Turkeys (one cock, two hens)	10.00 to 15.00

FANCY POULTRY.

Guinea or Pea-Hens	12.00
Pheasants, *English*, per pair	20.00
" *Golden*, "	35.00
" *Silver*, "	30.00
Pea-Cocks, per pair	20.00 to 75.00
Bronze Wild Turkeys	15.00 to 20.00
White Turkeys	10.00 to 15 00
Bantams, trio	3.00 to 10.00
Ring-Doves, per pair	1.50
Pigeons, *common*, per pair	0.75
" *all white, common*, per pair	1.00

BIRD FANCIERS' MATERIALS.

Breeding Cages (double)	1.50 to 4.00
Trap Cages	0.75
Wire " painted	0.50 to 4.00
Wood and Wire Cages	1.50 to 4.00
Prepared Bird Food, per quart	0.30
Bird Gravel, per quart	0.05
German Rape Seed, per quart	0.20
Canary Seed, per quart	0.20
McAllister's Mocking-Bird Food, 1lb. jar	0.35
" Canary-Bird Food, 1lb. box	0.20
" Mixed Bird Seed, 1lb. box	0.10
" Extra Silver Bird Gravel, qt. box	0.10
McAllister's Prepared Fish Food, per box	0.10
" Song Restorer, for birds, per bot.	0.25
McAllister's Bird-Lice Destroyer, in patent bellows box	0.25
McAllister's Bird Lime, per box	0.25
Cuttle-Fish Bone, each	0.05
Meal-Worms, per hundred	0.40
Nest Boxes, wire and tin	0.10 to 0.15
Nest Material, per bunch	0.10

QUADRUPEDS.

Terriers, *black and tan*, each	5.00 to 30 00
Terriers, *Scotch and Skye*, each	5.00 to 30.00
Newfoundland Pups, each	10.00 to 15.00
Pomeranian or Spitz "	5.00 to 15.00
Greyhounds, *English*, "	10.00 to 25.00
Greyounds, *Italian*, "	10.00 to 30.00
Guinea-Pigs, *common*, per pair	1.50
" " " " large	1.50 to 3.00
Guinea-Pigs, *all white*, "	2.00
Squirrels, *gray*, "	5.00
Squirrels, *all white* "	15.00 to 25.00
Squirrels, *flying* "	3 00 to 4.00
Squirrels, *small red* "	2.00
Rabbits, *common*, per pair	1.00 to 2.50
Rabbits, *fancy breed*, according to age and purity of breed, per pair	3 00 to 15.00
Ferrets, *English*, "	15.00
Raccoons, each	4.00 to 5.00
Cats, *Maltese* (males), each	5.00
" " (females), each	3.00
Cats, *Albinos, pink or blue eyes*, each	3.00 to 5.00
Rats, *white China, pink eyes*, per pair	1.50
Rats, *piebald*, per pair	1.50
Mice, *white, pink eyes*, per pair	0.50
Mice, *piebald*, per pair	0.50

Prices Paid for Pet Stock by Dealers.

Guinea-Pigs, per pair	$0.40
Squirrels, *gray*, each	0.50
Squirrels, *flying*, per pair	0.75
White mice, per pair	0.15
Monkeys, according to variety	15.00 up.

MARINE AQUARIA STOCK.

Purple Bermuda Anemone	2.00
Fringed Sea Anemone, Medium-sized specimens	1.50
White-Armed Anemone	0.50
Small Orange "	0.10

SHELLS.

Collections of small "cabinet" shells for schools, private cabinets, range from $5.00 to $50.00.

Mother-of-pearl shells, for painting, 75 cts. to $1.50.

Single specimens of cabinet shells range from 15 cts. each to $3.00.

Masses of corals, 25 cts. to $3.00.

Green snail and cowry, with the Lord's Prayer engraved on them, 50 cts. to $2.50 each.

Conch shells, for mantels or hearthstone ornaments: West India Conch, 25 cts.; East India Yellow Helmet, $1.00 to $2.50; Bahama Black Helmet, 50 cts. to $1.50; Bahama Hatchet Helmet, 50 cts. to $1.25. These shells are also for cameo engraving. Zanzibar Cameo, 25 cts. to $1.00.

Ground and polished shells: New Zealand Green Ear, 50 to 75 cts.; New Zealand White Ear, 50 to 75 cts.; Japan Black Ear, 50 cts. to $1.00; California Red Ear, 75 cts. to $1.25.

Fine shells for fancy work, according to colors and variety, per quart, $1.00 and up.

Fancy Wood for Scroll Sawing.

The prices given for the various woods used in this work are for the best of qualities of seasoned material, planed on both sides, ready for immediate use. They can be furnished in quantities to suit purchasers. Prices are by the square foot, and vary according to thickness of material.

For all information on this subject, as to reliable dealers, etc., etc., send postal card to YOUNG SCIENTIST. When desired, the goods can be sent through this office, but in all cases remittances must accompany the order.

EXCHANGES.

Only those who are *yearly* subscribers, and whose names are entered on our books have the privilege of inserting exchanges.

Exchanges must be on separate slips of paper or postal cards. If mixed with business matter in letters or cards they are filed away and never reach the printer.

Exchanges must not exceed thirty words.

Buying and selling belong to the advertising department.

We reserve the right to omit the exchange column, when we have not room for it, and the amount of space at our disposal will regulate the number of insertions given to each *exchange*, the preference being always given to those who have not previously used our columns.

A number of first-class tricks, trick books, stamps, coins, Confederate money, curiosities, etc., to exchange for stamps or pet stock, such as rabbits, Guinea pigs, or squirrels. J. S. Reese, 52 Cedar St., Canton, Ohio.

Shell boat, Spanish cedar, 28 feet long, spoon oars; good order; been used but little; for offers. J. W. B., Carmel, N. Y.

Rowing machine, cost $10; photographic outfit, $16; Flobert rifle, $15; medical battery, $10; "Wood's Botany," etc.; for elk horns, deer horns, minerals, Indian relics, and all kinds of curiosities. would like list of curiosities from dealers. Chas. C. Collier, 3617 Locust St., Philadelphia, Pa.

Vol. III. of the *American Machinist* for the best offer of minerals. J. A. S., P. O. Box 83, East New York.

I have five or six complete years of the *Galaxy* (magazine) also a number of odd copies; I will exchange the lot for an induction coil in good condition, and giving at least a ¼ in. spark. W. B. Greenleaf, 480 La Salle Ave., Chicago, Ill.

I have eighteen numbers of the *Harper's Young People* (79 to 96 inclusive), containing part of the story "Tim and Tip," by James Otis, and all of the story "The Cruise of the Ghost," to exchange for a good spyglass, a good bull's-eye lantern, or a small telephone. J. H. Gamsey, Box 25, Wilmington, Will. Co., Ill.

A good violin, bow, box, books, all complete, worth $12.00, to exchange for Wood's Botany, Young Mechanic, or scientific books and papers; send list. A. D. Chamberlain, Trout Creek, Del. Co., N. Y.

A model self-inking printing press, chase 2½ x 3¼, 4 fonts card type, 3 type cases, ink, roller and furniture all in good order, to exchange for a good silver watch and nice chain. G. E. Wilmot, Box 88, Lebanon, N. H.

Any person wishing to exchange foreign stamps please send sheet and I will return it with mine. Box 90, Melrose, Mass.

New Nickels (without "cents") for offers; I also wish to exchange with curiosity, coin and stamp collectors residing in foreign countries. G. S. Griffin, Moline, R. I. Co., Ills.

1 Sea bean, 1 alligator's tooth, 1 small cocoanut, 1 liver bean, lot of other beans and shells and 50 foreign stamps for a printing press and outfit, size of chase about 6¼ x 4 inches; send postal. Geo. O. Riphard, Westminister, Md.

W. C. Roseboom, Cherry Valley, N. Y., wishes to exchange with amateur photographers, or others; photographs and pictures taken by themselves, mounted or unmounted; give name of picture and camera.

I would like to exchange minerals, stamps and curiosities for the same. O. J. Lache, 1313 Poplar St., Philadelphia, Pa.

6 fonts type, 4 cases, 2 composing sticks, leads, rule, etc., outfit except press, to exchange for good tent, not less than 6x6, or offers; send card before exchanging. Wm. O. Brown, Middlebury, Vt.

I have double barrel muzzle-loading shot gun, watch, orguinette, harmonica, stuffed birds for Household microscope, photo. outfit, books on natural history; specimens or offers. E. O. Tuttle, Bristol, Vt.

A printing-press, chase 5½ by 7 inches, in good order; will exchange for a large self-inking press or type. A. W. Barrett, Canajoharie, N. Y.

A one-keyed flute and pair of No. 10 club skates for rifle; E-flat cornet, cost $25, for an eight or six-keyed flute of equal value; all good; or offers. J. L. Pilkington, Pearsalls, L. I.

For fossils or minerals; fine specimens of Pentremites—two varieties—from sub. carb. rocks; also Flobert rifle, in good condition, and McKinnon pen. M. H. Crump, Bowling Green, Ky.

I have for exchange a collection of about 80 species of fine fossils, all named and making a fine collection, which I wish to exchange for opera glass, microscope, telescope, or offers; correspondence solicited. A. Stapleton, Box 756, Seneca Falls, N. Y.

Wanted, amethyst, moss agates, trilobites, geodes, coral, and coal ferns in exchange for fifty Indian arrowheads, coquina rock and Florida moss. E. V. Sheerar, Wellsville, N. Y.

"Crystallography" (40c.); "Electricity" (40c.); "Selection and Use of Microscope," abridged, (30c.) Either in exchange for "Workshop Companion," or two for "The Microscope," by Ross, or offers. C. H. Denniston, Pulteney, N. Y.

Home Medical Battery, cost $7; Lemair's Field-Glass, No. 2202 of Queen's Catalogue, cost $15.50; Achromatic Spy-Glass, power 25 times. To exchange for books or offers. Emerson Heilman, Heilmandale, Pa.

A small collection of coleoptera, comprising 100 species and 300 specimens, all correctly named, in exchange for bird-skins, insects, books, or eggs. Emil Laurent, 621 Marshall St., Phila., Pa.

A small magic lantern, Ruby pattern, with twelve slides, for a good book on Entomology, with illustrations. Willie R. Hotchkiss, Morrisdale Mines, Clearfield Co., Pa.

Wanted, Thompson's "Witchery of Archery." Must be in good condition. Write before you send. J. Anthony, Jr., Coleta, Whiteside Co., Illinois.

A telescope worth $3.50, for a self-inking printing-press and outfit; chase not less than 2½ by 3½ in. Eddie Judd, 260 Connecticut St., Buffalo, N.Y.

To exchange for offers: $20 scroll-saw, Seneca Falls make, $4 Bailey circular plane, set of Auburn metallic planes, brass-bound four-foot rule, fourfold, Traut's patent combined plow, dado, etc., cost $7. F. A. Rappleye, P.O. Box 12, Farmer Village, Seneca Co., N.Y.

Bee Hive wanted; one of the old-fashioned straw "skeps"; say what you would like in exchange. Apis, care of Young Scientist, 294 Broadway, N. Y.

A first-class type writer, in excellent condition, cost $125.00, to exchange for good microscope, telescope, or valuable scientific books; send full particulars. A. B., Box 114, Lewiston, Maine.

A $30 stencil outfit (Spencer's) for a self-inking printing press in good condition, chase about 6x9; rich ores and minerals of Idaho for scientific and instructive books, printing press, type, etc. J. P. Clough, Junction, Lemhi Co., Idaho.

Wanted pyrites of iron from Colorado gold mines in exchange for sea shells and other gems; send list of what you have to exchange. S. Ferguson, Eureka Springs, Arkansas.

A banjo in good condition, two pairs of rosewood bones, three splendid games, and a fine set of drawing instruments, for a good cornet, viola, violincello or double bass. L. B. Hill, Kalamazoo, Mich.

Scientific specimens of various kinds for same. Geo. E. Frazier, Caldwell, Ohio.

Lester W. Mann, Randolph, Mass., Box 162, has Demas scroll saw, lathe and tools, emery wheel; $20 worth patterns; Smithograph; large harmonica, cost $1.75; novelties in seeds; for large self-inking press or offers.

10 volumes Chambers' Encyclopædia, American Book Exchange edition (cloth); Bonanza printing press, chase 3x5, card type, ink roller; spyglass, power 10 times; for French triplet, 1-5 in., or offers. H. P. Nichols, P. O. Address, Bridgeport, Conn.

A good telescope, also foot-lathe and saw combined, each worth $10.00, for shells, fossils or relics. Independent, Conncautville, Crawford Co., Pa.

Birds' eggs to exchange for others; send list of what you have to exchange. Emil Laurent, 621 Marshall St., Philadelphia, Pa.

Twelve or fifteen volumes of the American Agriculturist to exchange for scientific books or offers. W. H. Osborne, Chardon, Ohio.

Canaries: How to Keep and Breed Them.—IV.

BY GORDON STABLES.

THE weaning season lasts from the day they begin to crack seeds until they are at least six weeks old, by which time the egg-food, the supply of which has been given in daily diminishing doses, may be left off altogether.

If you intend to go in for what is called aviary breeding, you will have a deal more trouble, but also a deal more pleasure. In this case it is usual to turn in three males with twelve hens. My own advice is to turn in three males with only nine hens; that makes up the dozen, and there is more chance of strong healthy birds. The breeding season, begun in the middle of March, should end early in August, or last week in July. Sell your young birds if possible to private purchasers; if you cannot, then advertise them in papers devoted to live stock, etc. It is in selling especially that you find the advantage of possessing a good prize strain. There is nothing like pedigree animals for breeding purposes, no matter what they are.

I now come to say a few words about moulting. This is a most critical season with all birds, and the first moult of the young canary is eminently so. The moulting season for old birds generally begins some time in July, and extends over three or even four months, as a great deal depends upon the constitution of the bird, and how it is treated. Young birds show evidence of moulting sometimes as early as the seventh week, but any time between that and the tenth week is the usual time. When moulting begins among hen canaries, breeding should be brought to a close; if the male loses feathers first, it is the sign he is weak and the season is over; at any rate you must make it so. Put your hens by

themselves then in roomy cages, and the males either in separate cages or all together in one large one. Sell off all you do not intend to keep as soon as they are moulted. It is better to dispose of them at a reduced price than to keep them on for months in hopes of getting more money.

It is difficult for the amateur to learn to distinguish between male and hen in young birds. Experience alone can teach him this. The song, however, is nearly always conclusive, although instances are known, though far from frequent, of singing hens. There is, moreover, a different carriage in the male—he is neater, brighter, and bolder.

When your birds begin to moult, your object and your anxiety will bo to get them safely through it. Some first-rate breeders take little heed of the moulting season, and do not alter their usual treatment, and if a few die they do not bother. It is my own impression that birds not properly treated during the moult will not be so strong during the succeeding season. On the other hand, some people coddle their canaries far too much during moult. There is a medium in all things.

Birds are more apt to catch cold at this critical time, and if the cold strikes inwards, as the saying is, inflammation and death may ensue.

This fact ought to make us careful to keep the cages clear of draughts and free from damp. Even the room in which they hang should never be damp. The cages should be in a warm corner, and as warmth quickens the moult and causes it to be more perfect, it is a good plan to cover all the cage up except the front portion.

Do not be unmindful of the value of fresh air, therefore be careful to have the room properly ventilated every day by opening the windows at noon.

As usual, give fresh water daily, and for the first week or two a little aperient medicine may be put in the water every second day, either a small teaspoonful of carbonate of magnesia, or a little treacle. About the third week of the moult give a tonic by placing in the water a medium sized iron nail.

The food should be much as usual, only with the addition of egg and bread crumb, and any garden or roadside seeds the birds may fancy should be given. Do not forget green food, given sparingly. The bath should be allowed about twice a week. The plan of moulting birds off in dark rooms is, in my humble opinion, weakening to the system.

Every boy has heard of cayenne feeding during moult. It is a plan invented several years ago by, I believe, a noted breeder, to deepen and enrich the color of canaries. The fact that it does so is undisputed. Why it should do so no one can rightly explain; and the question whether or not it injures the constitution of the bird is a vexed one, so that we shall not enter into it. If you mean to adopt the plan, you must get the very purest cayenne that can be got. The condiment is mixed with soft food, especially with egg and biscuit crumb, the proportion being one hard-boiled egg mixed with say three small milk biscuits well grated, and a large teaspoonful of K.N.

Begin to give this about the age of six or seven weeks, when the feathers are still in the skin. Do not give very much seed at the same time. From one to two or more spoonfuls of the K.N. food may be given to each bird daily.

Saffron cake is sometimes given to birds during the moulting season, and a little syrup of saffron, about a teaspoonful, might be placed in the drinking water occasionally.

If you wish a bird to be particularly fond of you, single one out—a bright, smart, saucy male—and put it in a cage by itself. It must, of course, be young. Feed it yourself and talk much to it, and whenever it comes towards you give it a tiny bit of some dainty. You will soon have it so tame that you may open the cage door and let it out. If you take no notice of it, it will come by-and-by and perch on your shoulder, on which you may place some dainty morsel. When it retires of its own accord shut the cage door, but not before. The great secret of taming birds, or winning the affection of any animal, is summed up in one sen-

tence—Be always kind to them; let them be in every way dependent on you, but never try to force their affection.

(To be concluded.)

Amateur Boat-Building.—VI.

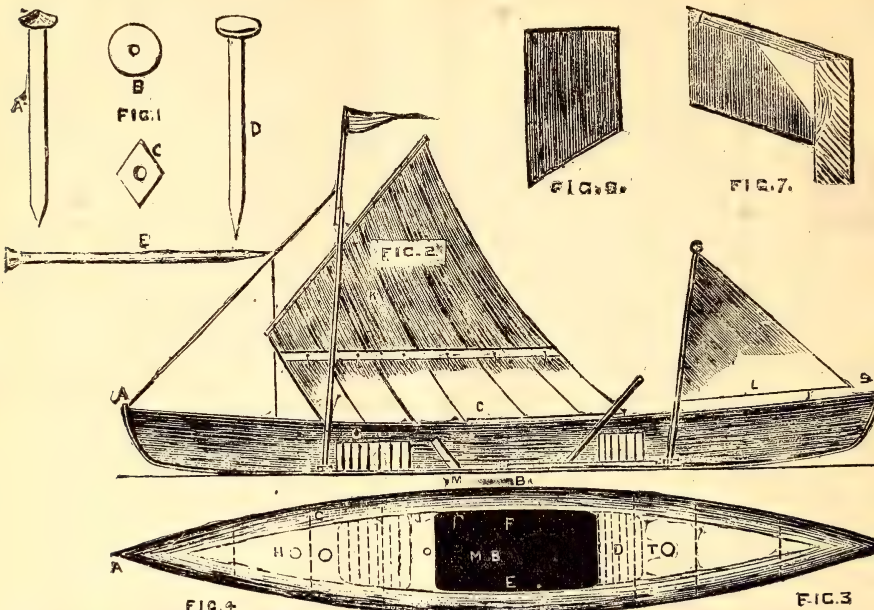
VARIOUS sizes of nails are used in boat-building, according to the particular purpose for which they are required. They are made either of copper or of iron, those of the latter metal being occasionally tinned or galvanized, but not usually. For general purposes, copper nails are to be preferred for fixing the skin of the boat, although iron nails are employed by some professional builders for light craft. The most usual form of boat nail is that shown at A, Fig. 1. This nail is square, has what is known technically as a "rose" head, tapers towards the end, and terminates blunt and square. This blunt end is found better adapted for certain purposes than if the nail were pointed. With this boat nail is used the "rove," B Fig. 1, which is a small perforated metallic disc. In fixing on the planking of the boat, the nails are driven from the outside, and are always of sufficient length to leave a portion inside the boat after the wood has been pierced. When the entire skin of the boat has been thus nailed on, a rove is slipped over the point of each nail, of which latter any superfluous portion more than is sufficient to form a good rivet is cut off by the aid of a pair of boat-builder's nippers, which cut at the ends; the remainder of the shank of the nail is then carefully riveted down with a light hammer upon the rove.

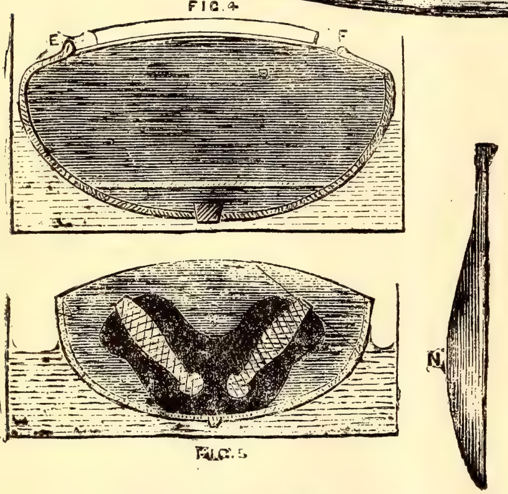
This rivetting the shank of the nail down upon the rove brings the planking close, and makes a good job. The rove is usually circular in form, as shown at B, but formerly a diamond shape C, Fig. 1, was more common. Beside the regular boat-nail, the clout-nail D, Fig. 1, is often used, the rove being dispensed with, and the portion of the end which projects inside being beaten down on the wood in the direction of the grain. and struck with the hammer, so that it sinks into the boarding. This is called clinching. If the nail projects more than a quarter of an inch, the surplus portion must be cut off, as in the case of the roved-nail. Clout-nails are square, like boat-nails, but have a flat, round head instead of a rose head. The size of the nail will, of course, depend upon the class of work for which it is to be used. From 14 to 17 gauge are employed for light craft, with Nos. 1, 2, or 3 roves. Boat nails and roves cannot often be procured of ordinary hardware dealers. Our builders may, however, get them, and all other kinds needed for boat-building by sending to this office where we will furnish small quantities to amateurs. Nails of much larger size than those specified noted in the proper place. The French wire nail E, Fig. 1, is somtimes employed for light boat-building, its tenacity rendering it very suitable for easy clinching. This is a round nail, and is used without a rove. In light work it is best to employ a fine bradawl to bore a small hole for the boat, or clout nail. The French nail (*point de Paris*) being sharp, does not need this preliminary, as there is little fear of its splitting the wood.

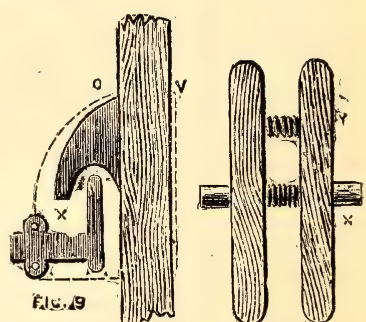
As there have been several requests from our readers for information about canoes, especially of the "Rob Roy" form, introduced by Mr. Macgregor, we will alter our original order, and devote a short space to that subject before taking up punts, skiffs, etc.

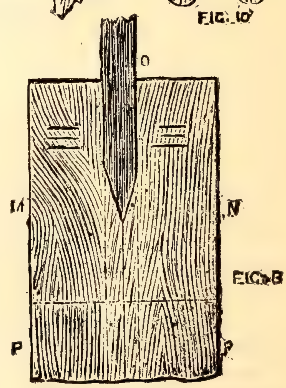
The "Rob Roy" canoe has well earned its celebrity as the best craft for general travelling purposes, and the amateur cannot adopt a better model. Several varieties and modifications have, however, been brought out since, some of which, as Alden's boat, the "Shadow," have attained considerable popularity.

Mr. Macgregor's first "Rob Roy" made a voyage of a thousand miles through France, Switzerland, and Germany; and his newer canoe navigated the Baltic, and went through much of Sweden and Norway. The "Rob Roy" was primarily—and, indeed, above all—a travelling craft, light, easily adapted to what the Canadians term "portage," or the capacity of being carried readily by land, strong, and

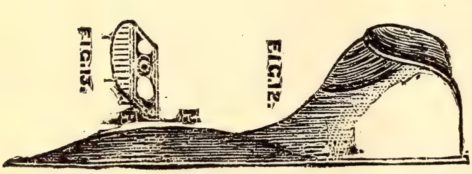








Amateur Boat-Building.



well arranged for facile paddling. The "Rob Roy," when completely fitted weighed 71 lbs. only, or without fittings 60 lbs. Mr. Macgregor considers that the stature, etc., of the canoeist is the proper regulating standard for his little craft. Thus it is the length of the occupant's foot which should determine the height of the canoe from keel to deck, the length of his leg settles the size of the well, and his weight (with travelling baggage, etc.,) governs the amount of displacement to be arranged for.

In the following description, given in great part in Mr. Macgregor's own words, a canoe is spoken of which is adapted for a man 6 feet high, 168 lbs. weight, and wearing boots whose soles are about a foot in length. The "Rob Roy" is decked, except where the canoest sits, and is built of oak, with a mahogany top streak, and a red cedar deck. The canoe has a mast which can be easily shipped or taken down, and a lug-sail. She is, of course, propelled by a double bladed paddle.

Fig. 2 shows section of the craft; Fig. 3, plan; Fig. 4, cross section at the beam; and Fig. 5, cross section at the stretcher; Figs. 10, 11 and 12, are the backboard and apron, the other sketches showing details.

The principal dimensions are: Length over all, A S, Figs. 2 and 3, 14′ from stem to stern, B, 7′ 6″; beam outside (6″ abaft midships) 2′ 2″; depth from top of deck at C, for'ard of the well, to upper surface of keel, 11″; keel, depth outside 1″ (with an iron band along the whole length ⅜″ wide); camber, 1″; depth at gunwale, 8½″. The upper streak is of mahogany, and quite vertical at the beam, where its depth is 3″. The garboard streaks, and the next on each side are light, as it is found that they are less exposed; but all the lower streaks are of oak. The stern and stem posts project over deck, so that the canoe, if turned over, will rest on these points, and on the upper end of the combing, round the well. The well is 2′ 8″ from C to D, and 1′ 8″ from E to F, so placed that D M is 2′, and thus the beam of the boat being abaft of the midships, the weight of the luggage, G, and of the masts and sails stowed forward, bring the boat to nearly an even keel. For a boat without luggage, the beam should be one foot abaft midships. The deck is supported on four carlines forward, and three aft, the latter portion being thus more strengthened, because in some cases it is required to support the weight of the canoeist sitting on the deck with his legs in the water, and each carline has a piece cut out of its end (see Fig. 7), so that the water inside may run along to the beam, when the canoe is canted to sponge it out. The after end of the carline at C is bevelled off (Fig. 6 in section) so as not to catch the leg. All the carlines are narrow and deep, to economize strength, and the deck is screwed to them with brass screws. A flat piece is inserted under the deck at the mast-hole, H, which is also furnished with a flanged brass ring. The deck is so arched as to enable the feet to rest comfortably on the broad stretcher, J, Fig. 5, the centre of it being cut down to a curve, in order that the masts and sails may rest there, and be kept above the wet under deck. The cedar deck round the well at E F, is firmly secured by knee pieces, and the boat may thus be lifted by any part, and may be sat upon in any position without injury. The floor boards about 2′ long, rest on the timbers until, at the part below C, Fig. 3, they end at P P, Fig. 8, in notched grooves, which fit into short oak pieces, M N, ¼″ thick, sloping down on each side of the keel, O, until they rest on the garboard streaks, and so lower the heels nearly 1″ below the level of the floor board on the top of the timbers.

(To be continued.)

BEARING REINS AND BLINKERS.—The *London Lancet* very sensibly argues that the bearing rein and the blinker or blinder should be abolished altogether. As regards blinkers, there are several reasons why these should be abandoned. Without them the horses are able to see the raising of the whip, and by answering thereto are saved the infliction of its stroke; their temper also is greatly improved.

The Attacus Cecropia.

BY A. W. ROBERTS.

ONE day, when wandering through the woods near the Cypress Hills Cemetery, I discovered a hedge-row of elderberry bushes on which were feeding many hundreds of young caterpillars of the *Attacus Cecropia* moth. Having my botanical collecting case with me, I filled it with leaves on which the caterpillars were feeding. At the time I write of I lived in Brooklyn, opposite the Capitoline Grounds. In these grounds, along the fencing, flourished numerous elderberry bushes. Now, here was an unusual chance to study the habits and transformations of this very beautiful creature, the *Attacus cecropia* moth, so I determined to start a cocoonery in my back yard by supplying these many hundred squirming pets of mine with a bountiful supply of fresh food every day from the Capitoline Grounds. First I captured all the glass preserving jars in the cellar. These were placed closely together in a long row; they were then filled with water, and into each jar was crowded numbers of medium-sized branches of the elder. When the caterpillars were comfortably established in their new home, I felt well rewarded for all the trouble I had taken. It would have done your heart good to see them pitch into the fresh and tender leaves of the elder. By placing my ear to the end of the fire-board on which the water jars stood, the hundreds of crunching jaws of these beautiful worms could be distinctly heard as they mowed down the succulent elder leaves. But, alas, trouble and danger came in the shape of a small and vicious looking wasp-shaped fly. I had often noticed numbers of these creatures hovering over and about my silk-worm establishment, and I began to fear that they were up to mischief of some sort. At last I caught one in the very act; I saw him dart down on one of the worms, touch him with his abdomen but for an instant, and then fly off. The caterpillar jerked his head backward to his side, as if in intense pain, at the same time drawing his body up to its smallest compass. Presently another and another worm was struck by these villainous ichneumon

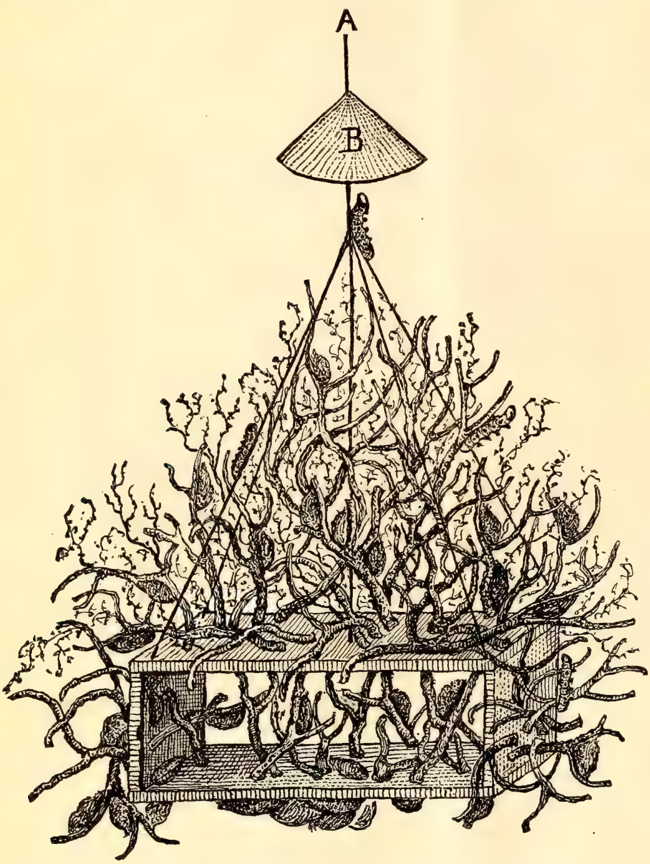


Fig. 1.

flies, for such they proved to be. Well, I knew that every caterpillar that had been struck by them would never develop into an attacus moth, though he would spin his cocoon and change into a chrysalis. This may seem contradictory, but it must be understood that when a caterpillar is struck by an ichneumon the fly drives his ovipositor deep into the flesh of the caterpillar, the result being that an egg of the ichneumon is deposited. When the caterpillar slips off his skin, after spinning his cocoon, this egg, passes into the body of the chrysalis, on which it lives. In the spring of the year, about the time the chrysalis would have changed into a cecropia moth, the now perfect larva of the ichneumon is strong enough to cut its way out of the silk material of which the cocoon is composed, and develop into a perfect ichneumon fly. To save my pets from destruction, I covered the elder branches with mosquito netting. In course of time numbers of the caterpillars began to act sluggish, and refused food, and I feared that they were sick; but such was not the case; they were going through a preparatory rest before commencing to spin their cocoons. Now I was very anxious to learn and understand all about this exceedingly interesting operation, so I devised a scheme by which I could imprison them, and at the same time have them directly under my eye. Procuring a starch box, which consisted of light wood, I withdrew the sliding top, and also removed the bottom, as shown in Fig. 1. To the upper four corners were attached four strings; these strings were gathered a yard above the box, as shown in the illustration. At the point where the four strings met was attached the single string, A, and to this string was attached a cone of heavy and highly calendered writing paper, as shown at B. The intention of this cone was to prevent the caterpillars from passing up the string A and escaping. I never knew one of my caterpillars to attempt to make his escape by dropping off from his place of imprisonment; they seemed to instinctively know they are of so fleshy a nature that such a proceeding would be certain death. Inside and outside of the box were fastened numbers of small elder branches, and on the top of the box was constructed a cone-shaped mass of the same material, which, to more securely hold it together, was tied to the four converging strings. This odd-looking structure, after being completed, was then charged with ripe caterpillars. At first they ceaselessly wandered over the branches, and up the strings to the paper cone; but at last the promptings of nature forced them to succumb, and they began to throw their silken webs, to spin their cocoons. Was I greatly interested? Well, yes. Did I reach the office late, very late, of mornings? Yes. Did my employers wonder what was the trouble? Yes, they did; and the leading editor inquired as to what new hobby I had got astride of this time? I frankly told him I had mounted and was riding tandem some two hundred caterpillars. Now, be

Fig. 2.

it known that this kindly person was the bug and botanical editor, so you can understand why my lateness of mornings was overlooked. After some thirty of the caterpillars had spun their cocoons on the elder branches, it occurred to me that it was to be regretted that a part of the great moving mass of human beings of New York City should be deprived of witnessing, enjoying, and learning a lesson in natural history by seeing this very interesting performance. And I took the circus over to F——g's seed store in Nassau Street, and hung it up in the window, just for the fun of it. The thing hadn't been on exhibition more than an hour before a messenger was at the office urging me to come and see Mr. F——g immediately, and that the front of his store was blockaded with people standing and looking at it, and that the policeman on that beat was trying to keep the sidewalk clear. Also, that they had forgotten the scientific name of the creature, and what would I sell them for apiece on the sticks? So I wrote out a label, giving the scientific name in large and plain letters, with a short history of the beautiful moth, and also attached to the label a magnificent mounted specimen of the attacus, stating the price of the cocoons to be fifteen cents each. In the afternoon, greatly to my surprise, twenty of the cocoons had been sold. My not seeming greatly rejoiced over the financial turn the exhibition had taken, F——g remarked "What's the matter, don't you want to sell them?" "No," I replied, "I wanted to keep them; I didn't suppose there was any demand for them. I brought them over to your store as a novelty, and to attract attention to your place of business. "Well," he replied, "they have attracted too much attention; the sidewalk has been constantly blocked, and half the time my clerks have not been able to put up our goods, from people constantly coming in and asking questions. Now I'll strike a bargain with you. I'll give you a hyacinth, tuberose, or gladiolus bulb for every cocoon that I sell, and that you are to keep up a constant supply of the caterpillars." To this I at once agreed. My friend F——g sold a great many of them, and I had a most satisfactory collection of bulbs in my garden next spring. I have always found a good demand for the cocoons of all the attacus family of moths. Such being the case, why don't some of our enterprising young readers go into the thing, not only for pleasure and profit, but also to take a lesson in silk culture, a subject that is attracting so much attention at the present time. I am of the opinion that by careful cultivation and selection, our native silk producing moths will eventually be found to be of great value. In Japan and China they utilize the silk of the cecropia for the manufacture of fabrics; then why not here?

Hints from India.

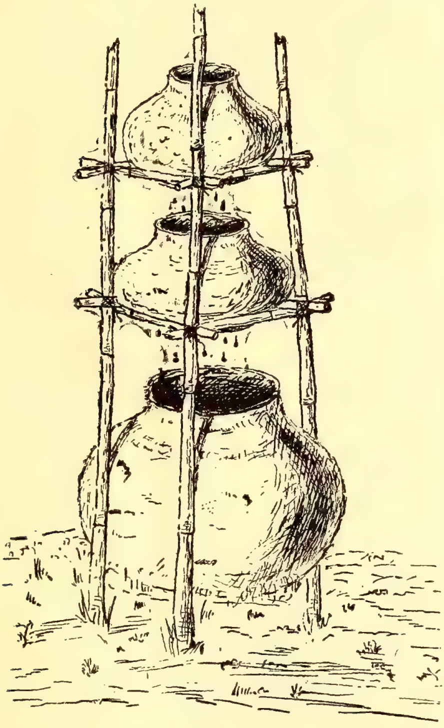
BY W. L. D. O'GRADY.

SCREEN DOORS.

IN India, most houses resemble Washington's Headquarters at Newburg in one respect. They have more doors than windows. Circulation of air is so necessary in the torrid climate that these doors are invariably left open; but in order to baffle too inquisitive eyes while not interfering with ventilation, they are supplemented by double screens, or half-doors, as they are called, which are hung just as we hang wire doors in summer, to keep the flies out and let in the air. They are light frames, covered with prettily painted paper, or chintz, or silk, and are about six feet long, reaching to about seven feet high, and leaving about a foot below, which sometimes has a valance to it, but is better without. In the lofty rooms, so characteristic of Anglo-Indian architecture, the effect of these light, graceful half-doors is very pleasing. They would be quite suitable for summer use here, and might be made quite inexpensively. No springs are needed, though of course such American improvements might be added, at some additional cost. The most stylish people in India are content with a simple slide, usually quite plain, which may, however, be elegantly carved.

CHEAP FILTERS.

The water in even the most picturesque well is sometimes anything but wholesome to drink. Filters are now recognized as among the necessaries of life. Most filters, however, of any reasonable size are rather expensive. In India a very cheap filter is used, which is practically as good as can be made, holds a large supply of pure water and cools it almost to freezing point—at any rate to a very refreshing degree of coldness, without the danger in it that lurks in ice water. It is made of bamboo, in the shape of a scaffold, with three or four large *chatties*, or



bulbous porous earthenware vessels, one above the other. The upper ones have holes at the bottom stuffed with rags, through which the cleansed water drips. The top one is half-filled with layers of coarse charcoal and pebbles, those next with the same, only finer. The bottom receptacle is usually surrounded with wet straw, and a straw mat to keep the spherical bottoms steady is supplied to each. All are thickly covered with a dew exuding through the sides, and by the evaporation cooling the contents. Such a filter in India costs about twenty-five cents. A good imitation, with very large unglazed flower-pots, instead of the *chatties*, could be made here, at a not very alarming advance on that sum. A corner of the cellar or woodshed might well be spared for such a filter.

Our Guessing Column.

BY A. W. ROBERTS.

NUMBER 1.—Who would ever imagine that money could be made by the sale of such a looking creature as the one referred to in this guess.

Nevertheless, I know of a young man who raises these insects by the thousand every year, and by the sale of them earns sufficient money to buy all his clothing. These creatures are to be had only in certain stores, and cost fifty cents a hundred. They are raised on bread, crackers, Indian and oat meals. To keep them warm and clean, they are placed between layers of blanketing. The parents have wings, and fly from place to place in search of food.

Now, my Yankee guessers, what can this insect be?

No. 2.—Once upon a time I met an old and very talkative German. In a large basket he carried a number of small glass jars, and in each jar was a pretty little wooden ladder, and on each ladder sat a quaint and very wise-looking animal in a gray suit. The expression of his eyes was particularly mild and soft. I knew this animal the moment I saw him, for when a boy I had caught many of them as they sat on the branches of trees, trilling their soft voices to one another. Now comes a curious fact about these creatures, which is, that when there is going to be a storm they climb to the topmost step of their ladders and send forth trill after trill—for they seem to delight in rainy weather.

The German charged two dollars for each jar and its contents. He informed me that for many years he had done nothing else, and that he had sold a great many. Now, my merry puzzlers, puzzle this out if you can.

No. 3.—Passing along Fourteenth street one clear and sunny day, I met a man who had for sale a number of "tame yellow birds," as he called them. It is true they were yellow birds, and would perch on his fingers or on his head, and would not attempt to fly away. Yet *they were*

not tame, nor were they sick, as they were very active, and seemed to enjoy themselves heartily.

Now, my young bird lovers, solve this mystery.

No. 4.—Early one dark morning, when crossing the City Hall Park, I was surprised and puzzled as to what a number of human beings were in search of at so uncanny an hour. Each person had an empty fruit can in his hand, while with the other he every now and then seemed to clutch at something in the short and scanty grass. After watching them for a time, I failed to reach a conclusion as to what they were seeking for, as they crept about on the ground in so stealthy and cat-like a manner. At last, overcoming my modesty, I boldly approached one of the seekers, and inquired of him why he was crawling on all fours. He told me why, and I asked him what for. He answered "For my rum in the morning."

Inquiring of another creeper, he answered, "For my pet in the morning."

Asking of another, he answered, "To obtain a breakfast for my wife and children in the morning."

What could be the object which these many human beings so eagerly sought on hands and knees? one for rum and misery; another from a strong attachment, and a third for the love and affection he bore his wife and children?

Fun From the Classics.

BY AN "OLD BOY."

REALLY, boys seem to take more interest in Greek and Latin than I thought possible. If we are to believe what certain educationists tell us, the study of the classics is rapidly dying out at school. Well, it may be so, but at any rate it is not defunct yet, for no one can find any pleasure in deciphering a macaronic or construing a puzzle who has not made some acquaintance with ancient authors. And that there are some who have found amusement in these studies I have reason to know.

A friend reminds me that we have not yet had *Pugno pugnas pugnavi*, a very old friend: "I have fought battles with my fist." This is tolerably easy; but which of you can construe the following:

"Carmina, carmina, carmina, carmina, carmina multa,
Carmina multa rogas: carmina multa dedi"?

The lines are supposed to have been written by a cheeky Etonian in reply to an exacting tutor. They are decidedly ingenious.

I have lately met with some very good macaronics: one, from which I will give an extract, is in an ancient number of "Punch," and is entitled, "The Death of the Sea Serpent, by Publius Jonathan Virgilius Jefferson Smith":

"Arma virumque cano, qui first, in the Monongahela,
Tarnally squampush'd the Sarpint, mittens horrentia tela.
Mighty slick were the vessel progressing, jactata per æquora ventis:
But the brow of the skipper was cloudy, cum sollicitudine mentis."

However, whilst bewailing their bad luck—

"He saw coming towards them, as fast as though to a combat 'twould tempt 'em,
A monstrum, horrendum, informe (cui lumen was shortly ademptum).
On the taffrail up jumps in a hurry dux fortis, and seizing a trumpet,
With a blast that would waken the dead, mare turbat et aëra rumpit—
'Tumble up, all you lubbers,' he cries—
'tumble up! for careering before us
Is the raal old Sea Sarpent himself, cristis masculisque decorus!'"

The epic goes on to relate how they lowered the boat and attacked the monster, who turns on them:

"But the bold skipper exclaims, 'O terque quaterque beati!
Now with a will, dare viam, when I want you be only parati!'"

Dare viam for "give way," is very fine.

He finally overcomes the serpent with a lance which *ad intima viscera mittit;* and the skipper's cry,

"'We've fixed up *his* flint, for in ventes vita recessit,'"

closes the poem.

Professor Smith, of the Blind Asylum at Louisville, Kentucky, wrote the following when a student at Yale College:—

(1) Felis sedit by a hole.
Intenta she cum omni soul,
Prendere rats.
Mice cucurrerunt over the floor,
In numero duo, tres, or more,
Obliti cats.

(2) Felis saw them oculis;
I'll have them, inquit she, I guess,
Dum ludunt.
Tunc illa crept toward the group,
Habeam, dixit, good rat soup,
Pingues sunt.

(3) Mice continued all ludere,
Intenti they, in ludum, vere
Gaudenter;
Tunc rushed the felis unto them,
Et tore them omnes limb from limb,
Violenter.

MORAL.

Mures ! omnes mice ! be shy.
Et aurum praebe mihi
Benigne.
Si hoc facis—verbum sat—
Avoid a huge and hungry cat
Studiose.

Let me give you a verse from a poem on Æstivation, supposed to have been written by a Latin tutor immured in a town during summer. Those who want the whole must look in Holmes's "Autocrat of the Breakfast Table" for it.

"In candent ire the solar splendor flames ;
The foles, languescent, pend from arid rames ;
His humid front the cive, anheling, wipes,
And dreams of erring on ventiferous ripes."

This is splendid. At first it looks like one of the poems out of "Alice in Wonderland":

"'Twas brillig and the slithy toves," etc.,

but when looked at more carefully it will be seen that the peculiarity consists in treating Latin words as English ones, not mixing the two together, as in the ordinary macaronic.

To finish with, we will have a few genuine pieces of translation by juvenile criminals—criminals in a literary sense only. There is a well-known sentence in Henry's Latin book, which runs, "Sagittae ab humero pependerent." "Pro causa troublam savendi," as "Punch" puts it, a boy treated "sagittae" as a proper name, with this result, "They hung Sagitta by his shoulder."

I have in my possession a recent number of the "F—— School Magazine" (I will be merciful, and not give the full title). The lower school has evidently been at work on Virgil, with the following results, as shown in examination papers:—

"Parvam te roscida mala vidi cum matre legentem" (Buc. viii. 38).

This was translated, "I have seen you, a not large girl, reading apples with your mother."

There is no doubt that this is terribly funny, but I can't help being rather angry with the boy who has so burlesqued one of the exquisite passages of the Bucolics. "Gathering the dewy apples" turned into "reading apples." O shade of Virgil!

"Frigus Captabis opacum"—"You will catch a heavy cold." Those who remember that the passage begins "O fortunate senex!" will appreciate the exquisite fitness of the translation.

"Flumine libant, summa leves" (Georg. iv. 54-5). The Editor of the magazine remarks, "The last two words were given with the peculiarly felicitous translation of 'summer leaves.'" I hope, by the way, that the examination papers did not contain the same errors as the magazine, or I could almost forgive the boys who failed to make sense of the passages. "Oviscus tos" for "Oves custos" is enough to put a scholar out, not to mention a boy who is capable of writing "red with the scarlet berries of the ivory," or "the strange sheep milks its guardian twice an hour."

Famous Popular Songs.

"AULD LANG SYNE" is popularly supposed to be the composition of Burns; but, in fact, he wrote only the second and third verses of the ballad as commonly sung, retouching the others from an older and less familiar song. "The Old Oaken Bucket" was written by Woodworth in New York city during the hot summer of 1817. He came into the house and drank a glass of water, and then said, "How much more refreshing it would be to take a good long drink from the old oaken bucket that used to hang in my father's well." His wife suggested that it was a happy thought for a poem. He sat down and wrote the song as we have it. "Woodman, Spare that Tree!" was the result of an incident that happened to George P. Morris. A friend's mother had owned a little place in the country, which she was obliged from poverty to sell. On the property grew a large oak, which had been planted by his grandfather. The purchaser of the house and land proposed to cut down the tree, and Morris' friend paid him $10 for a bond that the oak should be spared. Morris heard the story, saw the tree, and wrote the song. "Oft in the Stilly Night" was produced by Moore after his family had undergone apparently every possible misfortune. One of his children died young, another went astray, and a third was accidentally killed. "The Light of Other Days" was written to be introduced into Balfe's opera, "The Maid of Artois." The opera is forgotten, but the song still lives, and is as popular as ever.

Payne wrote "Home, Sweet Home," to help fill up an opera he was preparing, and at first it had four stanzas. The author never received anything for it; but, though the opera was a failure when played in the Covent Garden Theatre, the song took, and over one hundred thousand copies were sold the first year. In two years, the publishers cleared over $10,000 by the publication; and the variations, transcriptions, and imitations have been innumerable. The melody is believed to be a Sicilian air, and Donizetti has a variation of it in his opera Anna

Bolena. Payne was afterward appointed American Consul at Tunis, where he died, and whence his remains quite recently were brought to America. Some of his miseries may be guessed from his own words: "How often have I been in the heart of Paris, Berlin, London, or some other city, and have heard persons singing or hand-organs playing 'Home, Sweet Home,' without having a shilling to buy myself the next meal or a place to lay my head. The world has literally sung my song till every heart is familiar with its melody; yet I have been a wanderer from my boyhood, and in my old age have to submit to humiliation for my bread." Foster's "Old Folks at Home" was the best song he ever wrote. Over four hundred thousand copies were sold by the firm that first published it, and the author is said to have received $15,000 for his share in its sale. Christy, the noted minstrel, paid $400 for the privilege of having his name printed on one edition of "Old Folks at Home" as the author and composer. The song is thus often erroneously attributed to him. "Rock me to Sleep" was written by Mrs. Allen, of Maine. She was paid $5 for it; and Russell & Co., of Boston, who had in three years gained $4,000 by its sale, offered her $5 apiece for any songs she might write. Some years after, when a poor widow and in need of money, she sent them a song, which was promptly rejected. "A Life on the Ocean Wave," by Epes Sargent, was pronounced a failure by his friends. The copyright of the song became very valuable, though Sargent never got anything for it himself. "What are the Wild Waves Saying?" was suggested to Dr. Carpenter by a scene from Dickens' novel, "Dombey and Son," and the music was by Glover. "Poor Jack" was from the pen of Charles Dibden, the author of the Lamplighter. "Poor Jack" netted $25,000 for its publisher, and almost nothing for its author. "Stars of the Summer Night," a very famous song, especially for serenaders, was written by Alfred H. Pease, the noted pianist, whose sad death in St. Louis a few months ago was so greatly deplored by his friends. "Love's Young Dream" was one of Moore's best, but the tune to which it is commonly sung is from an Irish ballad called "The Old Woman." Moore sang his own songs so well that both his auditors and himself were often moved to tears. Once, when he was singing this song, a lady who heard him implored him to stop. "For heaven's sake, stop! This is not good for my soul." "Auld Robin Gray" was the work of Lady Anne Lindsay, who tells a curious story of the circumstances of its composition: "I called to my little sister, the only person near, and said, 'I have been writing a ballad, my dear. I am oppressing my heroine with many misfortunes. I have already sent her Jamie to the sea, and broken her father's arm, and made her mother fall sick, and given her Auld Robin Gray for a lover, but I wish to load her with a fifth sorrow within the four lines, poor thing. Help me to one.' 'Steal the cow,' said the little Elizabeth. The cow was immediately lifted by me, and the song completed." "Kathleen Mavourneen" was sold by Crouch, the author, for $25, and brought the publishers as many thousands. Crouch was hopelessly improvident, and in his latter days became a tramp. When Mme. Titiens was in this country a number of years ago, she sang "Kathleen Mavourneen" in New York, when a dirty tramp introduced himself as Crouch, was recognized, and thanked her for singing the song so well. "Bonnie Doon" was the only English song that the Emperor Napoleon liked. "I'll Hang my Harp on a Willow Tree" is said to have been written by a young English nobleman in love with Princess (now Queen) Victoria. "Annie Laurie" is two hundred years old, and was the production of a man named Douglass, to celebrate the praise of a girl named Laurie. The lady afterwards deserted the man who made her famous, and married a man named Ferguson.

A Beautiful Python.

IN the Zoological Gardens, London, can now be seen in all the velvety sheen of its first splendor, a python that has just cast its skin, and the great snake is a very miracle of reptillian loveliness. Not even the birds of paradise can compare with its purples, blues, and gold, while an infinite interest underlies those iridescent charms, from the fact that its coils, soft as a butterfly's wings, and shot with colors like a dove's breast, can crush the life out of a strong man, can hold the tiger in its range, and slowly squeeze it into pulp. Watch its breathing; it is as gentle as a child's. And the beautiful lamia head rests like a crowning jewel upon the softly heaving coils. Let danger threaten, however, and lightning is hardly quicker than the dart of those vengeful convolutions. The gleaming length rustles proudly into menace, and, instead of the voluptuous, lazy thing of a moment ago, the python, with all its terrors complete, erects itself defiantly, thrilling, so it seems, with eager passion in every scale, and measuring in the air with threatening head the circle within which is death. Once let those recurved fangs strike home, and, though there is

no poison in them, all hope is gone to the victim. Coil after coil is rapidly thrown round the struggling object, and then, with slow but relentless pressure, life is throttled out of every limb. No wonder that the world has always held the serpent in awe, and that nations should have worshipped, and still worship, this emblem of destruction and death. It is fate itself, swift as disaster, deliberate as retribution, incomprehensible as destiny. Gods and heroes alike held victory over the snake as the supreme criterion of valor. They graduated to divinity by slaying serpents. Indra and Vishnu conquer snakes. Hercules and St. George have their hydra, Apollo his python. It is over the body of Ladon, terrible progeny of a terrible parentage, Typhon its father and Echidna the dam—that the hero steps to gather the golden apples, and across the dead coils of Fafnir that Sigurd reaches out his hand to the treasurers of Brunhild on the glistening heath. What more fearful in Oriental myth than Vritna the endless thing that the gods overcome, or Kalinak, the black death, or Ahi, the throttler? Jason and Persens, Feridun and Odin claim triumph over the snake as their chiefest glories, and it would be tedious to recapitulate the multitude of myths through which "the dire worm" has come down to our times dignified and made awful by the honors and fears of the past. The python in the Zoological Gardens, however, though it may stand as the modern reality of the old-world fable of a gigantic snake that challenged the strength of gods to overcome it, presents to us only one side of the snake nature, surprising beauty and prodigious strength; but it is not venomous. Probably the more subtle and fearful apprehensions of men originated really from the smaller and deadlier kinds, and were then by superstition, poetry, and heraldry extended to the larger. The little basilisk crowned king of vipers; "the horned cerastes dire," a few inches in length; the tiny aspic, fatal as lightning and as swift; and the fabled cockatrice, that a man might hold in his hand, first made the serpent legend terrible; their venom was afterward transferred, and not unnaturally to the larger species. It was the small worms, that carried in their minute fangs such rapid and ruthless death, which first struck fear into the minds of the ancients, and invested the snake with the mysterious and horrid attributes whereto, antiquity, from China to Egypt, hastened to pay honor. Of the venomous snakes the Zoological Gardens presents many very fearsome examples, and painful death, such as science is as yet powerless to arrest, lurks within half the cases in the reptile-house. Eminent among the most deadly is the surucurn of the Brazils. Every one knows of the fatal daboia of India and the cobradi-capello, the rattlesnake, the ophiophagus, and the other more familiar reptiles with poison fangs, all of which are to be seen in Regent's Park; but the stranger from South America is their rival in the certainty and rapidity of the death that it inflicts. It and the python, therefore, may take rank as the representative of the two aspects of the snake idea in nature.

Camping Out.

THOSE who can afford it, take their summer vacation at the sea-shore or at some mountain resort. The object in selecting a locality, aside from those who are governed by fashion, being to find a place with surroundings as much unlike those at home as possible. But those who need the summer visit to sea-shore and mountain side, the farmers' and mechanics' hard-worked wives and families, can rarely afford the outlay required. A week at any of these public resorts involves an expenditure that is beyond the means of the majority. After all, the real objects of summer vacation is, change—a change of scene, a relief from the daily routine of household duties, a freedom, for the time, from care, and often a marked difference (sometimes for the worse) in the food. Besides these objects, there may be added the meeting with new people, and seeing new ways, which may or may not be desirable. All these results, save the last, can be had without expense, by a week or two in camp. A neighborhood must be poor, indeed, if it does not somewhere within a few miles, afford a pleasant spot for a camp. It may be by the side of a lake or a river, where fishing can be enjoyed; a hill-side or a mountain top may afford a pleasant place. A desirable spot can usually be found not far from home—indeed, we know of one farmer who does not go beyond the boundaries of his own estate to find a pleasant camping ground. If tents are not at hand, wagon covers, barn sheets, tarpaulins, or whatever will form a shelter from the dew and rain, may be pressed into the service. The chief point is have an abundance of bedding; buffalo robes and comforters, and a plenty of blankets, are usually sufficient, though some may need ticks filled with straw. In starting out for camp, do not take too many things. One of the useful lessons of camp-life is, to show how little one can get along with. The most important part of the outfit is, an abundant supply of good nature; a disposition to

make the best of everything, to overcome difficulties and be always cheerful. A grumbler is an unpleasant companion anywhere, but in camp he is a nuisance. In warm weather, the camp-fire should be at a good distance from the sleeping tents, and precautions taken that no spreading of the fire can occur. It is well to leave nearly all of the crockery at home, and provide a supply of tin plates, tin cups, and cheap knives and forks. Prepare in advance sufficient food to serve for the first two or three days, and then be governed by circumstances.

If the locality furnishes fish or game, the procuring of these will afford sport for the men and boys, but it is not safe to depend upon these, and there should be in reserve a ham, a supply of the standard camp-food, salt pork, which, with an abundance of potatoes, hard-tack, dried apples, and coffee, will keep the table well furnished. Have meals at stated hours, let each one in his or her way help in preparing them, and—what is still more important—help in clearing away and washing dishes. Keep the surroundings of the camp in good order. Have a pit in a convenient place for scraps and slops, and provide other conveniences in a sheltered place at a proper distance. If guns are taken into camp, let it be the business of some one to provide a proper place for them beyond the reach of children, and where no accident can occur. See that the guns are always kept there when not in use. Reduce the work to the smallest possible amount, so that the greater part of the day may be spent in rest—in "leisure," in the best meaning of the term. Be sure and provide an abundance of reading matter. Any hard-worked family will return from a fortnight's vacation, or a longer one, of this kind, better fitted to take up the home routine, and perhaps be more appreciative of home comforts.—*Agriculturist.*

The Modern Canoe.—Masts and Sails. Cooking Utensils and Food Carried in a Small Space.

"THE primeval canoe has passed through a process of evolution," said a manufacturer of light water craft. "The crude dugout was gradually improved upon until it resulted in the Indian's birch bark canoe. This was a fast and serviceable craft, but it was very far from being comfortable. The paddler sat on a wooden rod, instead of a seat, and the canoe was very cranky. By gradual development the Indian canoe has been made into the canoe of to-day. Cruising canoes are the most popular. The American Canoe Association has decided that a canoe to be entered for races must be a boat sharp at both ends, and not more than thirty-nine inches wide on deck. She may be propelled by sails or paddles, or both, but she must be capable of being effectually propelled by a double-bladed paddle. The best canoes have air chambers at the ends, which will float the crew and cargo even if the canoe is stove in. Canoes usually have the keel, bottom, and stem and stern posts of oak, while the sides and top are of cedar. The ribs are of red elm, and the coamings of oak. They are copper fastened throughout, and finished with oil. Bulkheads are built forward of the cockpit for dry storage. The craft is steered by the feet of the paddler by means of a simple steering gear. A canoe to be complete needs a various equipment. The fittings for the canoe itself are a rudder, steering gear, a cushion, backboard, paddles, masts, spars, sail, ropes, blocks, and cleats. One of the most popular models has the following dimensions:—Length, 14 feet; beam, 26 inches; depth amidship at gunwales, 8 inches; at ends, 13 inches; rise of deck, 3 inches; cockpit, 18 by 60 inches."

"Where are canoes built?"

"Many boat builders will turn out a canoe when ordered, but the best are made by special canoe builders. The demand for them has increased so much during the past five years that there are several large canoe yards scattered around the lake regions. Centreboard canoes are quite popular. They average 15 feet in length, and are made very stiff. They are completely equipped with masts and sails that can be unshipped and stowed away when the voyager paddles. There is no end to the things a canoeist needs when making a cruise, and enthusiasts are constantly at work perfecting little labor and space saving devices. There is a place in a well-run canoe for everything that is needful for comfort, and every thorough canoeist keeps everything in its place.

"One of the most recent of the many contrivances is a sort of housekeeper's box, which is made to fit in a special locker in the canoe. It consists of a light tin box 8 by 12 by 5 inches, divided into compartments. One section has three movable trays for bacon and crackers. Next are two boxes for oatmeal and rice respectively. Then there is a large box for flour. Next is a compartment in which can be packed three pails, a fryingpan, a saucedish, a boiler, and some small tin pie plates. All these utensils are made so that they fit into each other. The four corners of the main box are for pepper and salt. In the middle of the whole thing is a place for ice, with a compartment for butter next to it. All this

takes up considerably less than a cubic foot. Then there are perfectly made stoves, all complete, which can be packed in a space of about 10 inches square. A modern canoe carries every necessary for a cruise in a remarkably small space. It is not to be wondered at that canoeing is popular."—*Albany Journal.*

Coleoptera.

BY MARY H. WHEELER.

In the field of a farmer a young student strayed,
And in language of science most bland,
He soliloquized thus of the specimens laid
In a box which he held in his hand:

"The antennæ geniculate, here at the joint,
And the head is prolonged like a snout;
To the tribe of *Rhynchophora* that seems to point,
Yes, and there it belongs, without doubt.

And in this the elytra are yellow and black,
With the striæ just five on each sheath;
And the large under wings lie close down to its back;
Mesosternum points forward beneath;

The prothorax is spotted and covered with dust,
And the mandibles move with some force;
Can it be the *Doryphora?* Surely it must—
The *decem-lineata*, of course."

The old farmer was standing a moment to rest,
With his arm round the horn of an ox,
With the large-sounding words he was greatly impressed,
And he looked in the scientist's box.

Then he laughed a haw! haw! and a merry ha! ha!
And he bent and he shook with his laughter.
And the echo that dwelt in the hillside afar
Caught the sound and repeated it after.

And he said, as the student looked on in surprise,
"Now, stranger, I mean ye no evil,
But to think of your holding, while talking so wise,
A potato-bug, there, and a weevil!"
And he laughed and he shouted, with tears in his eyes,
"A potato-bug, oh! and a weevil!"

Pittsfield, N. H.

—Human foresight often leaves its proudest possessor only a choice of evils.

—There is nothing more universally commended than a fine day; the reason is that people can commend it without envy.—*Shenstone.*

Our Girl's Department.

This department is intended exclusively for "Our Girls," and we hope to make it both interesting and instructive, and to this end we ask our young lady readers to assist by contributions, suggestions, or illustrations. There are thousands of little things that can be, and have been, made and done by young ladies, pertaining to decorative art, needle-work, etc., etc., that would be gladly followed but for a want of knowledge on the subject, and we know of no more pleasing task for a lady than that of teaching her younger sisters that which they are anxious to learn, and which may prove of real benefit to them in the future, as well as being useful and interesting for the present. We trust we will have no difficulty in persuading those who have something nice to show or speak of, to make use of this department. Remember, it is open to all, and if you have anything worth knowing suitable for this column, send it along, and we will give it our best attention. Do not be afraid to write because you may fancy your composition is not perfect, or have other scruples of a similar kind. Do the best you can, and leave the rest to the editor of this department, and we are sure you will be pleased with your work.

—There lies across the mother's knee,
And gathered in her hand,
A little robe of puffs and lace,
With an embroider'd band.
I see her smile, I hear her sing
A low, sweet lullaby;
And oft, I see a thought of joy,
Light up her bright blue eye,
It is a robe for her dear child
To be christen'd in!

There lies across the mother's knee,
And gather'd in her hand,
A silken robe, with puffs of lace,
And an embroider'd band.
'Tis white, and like a cloud at eve,
That floats across the sky;
But oh, I hear the mother give
An oft repeated sigh.
It is a robe for her dear child,
To be wedded in.

There lies across the mother's knee,
And gather'd in her hand,
A robe of softest wool; but it
Has no embroider'd band.
And on her cheeks so wan and pale,
The mother's tears I see,
And hear her pray, Lord, give me strength!
Oh! give Thy strength to me!
It is a robe for her dear child,
To be buried in!

—To rule one's anger is well; to prevent it is better.—*Edwards.*

—He who foresees calamities suffers them twice over.—*Porteus.*

— Censure is the tax a man pays to the public for being eminent.—*Swift.*

— He is the best accountant who can cast up correctly the sum of his own errors.—*Nevins.*

— Rest satisfied with doing well, and leave others to talk of you as they please. —*Pythagoras.*

— Affliction is the good man's shining scene;
Prosperity conceals his brightest ray;
As night to stars, woe lustre gives to man.
—*Young.*

— Disparage and depreciate no one; an insect has feeling and an atom a shadow. *Coleridge.*

— Education begins the gentleman, but reading, good company, and education must finish him.—*Locke.*

A grateful mind
By owing owes not, but still pays; at once
Indebted and discharged.
—*Milton.*

Any one may do a casual act of good nature, but a continuation of them shows it is a part of the temperament.—*Sterne.*

— We should never make enemies, if for no other reason, because it is so hard to behave toward them as we ought.—*Palmer.*

— Singular that the word miser, so often expressive of one who is rich, should in its origin, signify one that is miserable.—*Browne.*

— Receive no satisfaction for premeditated impertinence; forget, forgive it, but keep him inexorably at a distance who offered it.—*Lavater.*

— The country is the philosopher's garden and library, in which he reads and contemplates the power, wisdom, and goodness of God.—*Penn.*

— Affectation in any part of our carriage is lighting up a candle to our defects, and never fails to make us be taken notice of, either as wanting sense or sincerity.—*Locke.*

— There cannot live a more unhappy creature than an ill-natured old man, who is neither capable of receiving pleasures, nor sensible of doing them to others.—*Sir W. Temple.*

— If a man does not make new acquaintances as he advances through life he will soon find himself left alone. A man should keep his friendship in constant repair.—*Johnson.*

— It is doing some service to humanity to amuse innocently: and they know very little of society who think we can bear to be always employed either in duties or meditations without any relaxation.—*Irving.*

— A contented mind is the greatest blessing a man can enjoy in this world; and if in the present life his happiness arises from the subduing of his desires, it will arise in the next from the satisfaction of them.—*Addison.*

— The grandest treasure it is possible for man to possess on earth is a good wife. The poorest investment he can ever make is a worthless one. Personal adornment may please the eye of the vulgar, but it will not hide a false heart. Sin may cloak itself for a brief season in the garment of hypocrisy, but sooner or later it shall come to judgment. Pure affection is a priceless jewel, the embodiment of earthly bliss. In the true union of husband and wife money should not enter into the consideration. The happiest homes the world ever knew have been bought and paid for by mutual earnings after marriage. The good and true wife adorns her home and makes it a little heaven. It is the abode of a royal family, a king and queen dwell within. There are no false gods in such a household.

— Well is it for the woman who is shielded and guarded through life. There are many lovely qualities to be developed only in such a protected condition. But sudden changes are injurious in propor-

tion to the delicacy of the organization. The old simile of the woman and the plant holds good in that respect. It is probable that, with the most favorable development of freedom, women will always be inferior in judgment to men; always more liable to make fatal mistakes in the conduct of life. If they are to be always under guardianship, let there be always a guardian. If they are to have responsibility, that doubtful good, let them as far as possible be fitted for it. Do not rely too much upon your daughter's good sense, fond parent. Your boy may do unwise and even wicked things, and may be a grief to you for a time, and yet go back and begin an honest life and be honored and happy, and all the past is forgotten; but your girl may do no wrong thing at all, and yet entangle herself so that she is unhappy and out of place for the rest of her days. It lies with no parent to insure happiness for his children. That is true. But in the large number of cases much may be done to lessen the probability of misfortune. Watchful care does not mean lack of trust, and native good sense is not ill supplemented by an education that teaches the girl something of the conditions in which she will be called upon to act.

— Two gentlemen, at a large reception in New York last winter, were discussing one of the foremost politicians of the country—a man who, whether in office or out, always keeps himself prominently before the public. "I knew him at college," said one of the gentlemen. "He was a man with a clear head, extraordinary memory, and much personal magnetism. But I cannot understand why he chose a public life or has pushed himself forward so persistently. He was a lazy, thoughful, visionary fellow, absolutely destitute of ambition." "I can tell you the secret," said the other. "You will find it in his wife's nose. There she is! did you ever see a more perfect incarnation of energy and love of command? Napoleon would have chosen her for one of his Marshals at first sight." His friend was amused at the guess, and said, presently:—"There is another of my old class-mates, P. He was a thin, ambitious, scholarly fellow, with refined tastes and high aims. He now is a fat, indolent animal, without a thought, apparently, but his cognac and terrapin. Who is to blame for that?" "His wife's mouth and her money. I will show her to you." He pointed out a gross, voluptuous woman, richly dressed. "P.," he resumed, "has lived in idleness since his marriage. He was not strong enough to carry the weight of so much wealth and so much vulgarity. They have borne him down. He will never rise." Young men at school and college are very apt to be enraptured with a sparkling eye, a rosy cheek, or some charm of manner in some young woman that they happen to meet. They are hardly masters of themselves; and a moonlight night, or a song, suddenly tempts them to ask the enchanting creature who has bewitched them to share their future. They do not consider that she will be the most real, active force in their whole lives, almost irresistible, with power to drag them down or to lift them up in body, mind, and soul.

— That was an unprecedented wedding, the recent one in Paris, of Rothschild's daughter to the banker Ephrussi. Over two thousand of European *elite* witnessed it, the array of dress, jewelry and beauty being bewildering. The splendid synagogue was Orientally draped in crimson and gold, rare exotics, growing fruits, and ravishingly odorous flowers abounding. The scene was one of rare magnificence. The bride drove up in an armorial carriage drawn by two splendid bays, a hum of admiration greeting her pageant. On entering the synagogue the males who were not Hebrews removed their hats, but were reminded by the *hussiers* that their people always remained covered in the temple and supposed presence of Jehovah, just as the favored Spanish grandees remained covered in the presence of their king. Two hours were consumed in the ceremony, the Grand Rabbi of France and the Grand Rabbi of Paris officiating; during it the retinue several times changing her trousseau. To gratify our lady readers, we

will tell them that the bride is but eighteen years of age, of medium height, slight and graceful form, a winning, pleasant face, transparent complexion, "a daisy" of a mouth, brilliant hazel eyes, and a wealth of brownish hair. She wore at first a dress of white satin with a very long train; this terminated in three points, the centre one being trimmed with orange blossoms. Her veil was of *point a l'aguille* lace. Among the splendid dresses she wore the most noticeable was a cream-colored velours epingle, with a very long train, the front of draped crepe, with the same color around the train, which had a wide border of variegated vine leaves, the tints ranging from dark green to russet red. The leaves were of velvet. On the left side of the jupe was a large cluster of velvet leaves. The corsage was pointed and decollete, trimmed with a garland of vine leaves. The wedding presents, in their multitude, beauty, usefulness and value, the local scribes say, defied description. One painful, heartrending fact, however, is dwelt upon, which is that among them was a *caveaux* from the baron father to the bride daughter of three hundred thousand dollars to furnish house with, and five thousand dollars per month with which to keep it. It is said that during the ten days preceding the wedding the bride received over 1,100 letters from destitute young ladies asking alms; not one unanswered or fruitlessly written. Was not that good and pretty of *la belle Rothschild?*

—A newspaper writer thus describes the ideal girl:—I saw a girl come into a street-car the other day, though, who had, I was ready to bet, made her own dress, and how nice she did look. She was one of those clean, trim girls you see now and then. She was about 18 years old, and, to begin with, looked well-fed, healthy, and strong. She looked as though she had a sensible mother at home. Her face, and neck, and ears, and her hair were clean—absolutely clean. How seldom you see that. There was no powder, no paint on the smooth, rounded cheek, or firm, dimpled chin; none on the moist red lips; none on the shell-tinted but not too small ears; none on the handsomely set neck—rather broad behind, perhaps, but running mighty prettily up into the tightly corded hair. And the hair! It was of a light chestnut-brown and glistened like specks of gold as the sun shone on it, and there was not a smear of oil or pomatum or cosmetic on it; there was not a spear astray about it, and not a pin to be seen in it. As the girl came in and took her seat she cast an easy, unembarrassed glance around the car from a well-opened gray eye, bright with the inimitable light of "good condition," such as you see in some handsome young athletes who are "in training." There were no tags and ends, fringes, and furbelows, or fluttering ribbons about her closely-fitting but easy suit of tweed, and as she drew off one glove to look in her purse for a small coin for fare, I noticed that the gloves were not new, but neither were they old; they were simply well-kept, like the owner and their owner's hand, which was a solid hand, with plenty of muscle between the tendons, and with strong but supple fingers. It would have looked equally pretty fashioning a pie in a home kitchen, or folding a bandage in an hospital. It was a hand that suggested at the same time womanliness and work, and I was sorry when it found a five-cent piece and had been re-gloved. One foot was thrust out a little upon the slats of the car floor—a foot in a good walking-boot that might have plashed through a rain-storm without fear of damp stockings—and an eminently sensible boot on a two and one-half foot, with a high instep, a small round heel, and a fairly broad tread. The girl was a picture, from head to foot, as she sat erect, disdaining the support of the back of the seat, but devoid of all appearance of stiffness. Perhaps the whole outfit to be seen, from hat to boots, did not cost $40; but I have seen plenty of outfits costing more than ten times or even twenty times that which did not look one-tenth or even one-twentieth as well. If our girls only knew the beauty of mere simplicity, cleanliness, and health, and their fascination!

THE
Young Scientist.

A Practical Journal for Amateurs.

(With which are incorporated "THE TECHNOLOGIST," "THE INDUSTRIAL MONTHLY," and "HOME ARTS.")

PUBLISHED MONTHLY AT $1.00 *PER YEAR.*

A Tempting Offer.

THE success which has attended our efforts during the past year, since the enlargement of the YOUNG SCIENTIST, has determined us to make it still better during 1884. We are now completing our arrangements for accomplishing this—making contracts with contributors, engravers, paper makers, printers, and others—and we are anxious to get our subscription list into shape as soon as possible. We have therefore determined to make the following tempting offer: To every one that sends to this office a subscription for 1884 at full rates, before the 10th of December next, we will send a copy of the "Workshop Companion." This is a book of 164 closely-printed pages, full of matter that is just what every one of our readers, boys and girls, wants. The price is 35 cents, strongly and neatly bound, so that those who accept our offer get the YOUNG SCIENTIST for almost half price.

If you want a copy of this work on these terms, send at once before you forget it.

It seems to be natural for every boy to possess a strong desire to stray from home and search in the outer world, as it were, for something different, and as they fancy better, than the surroundings they enjoy at home. This longing for change seems inherent in every boy of spirit, and is planted in him for a useful purpose, and is the very element that did the most towards peopling this continent. Boys, however, must submit to be guided by circumstances, and the wisdom of their friends, and under no consideration whatever, should a boy leave his home, for any length of time, without the consent of his parents or guardians. Indeed, boys should be well up in their teens before launching out on the wide world. There is no place like a peaceful home for opportunities of study and thought, and the bright and intelligent boy who spends his young days on the farm, or in the country village, stands a much better chance of success in after life, than the boy who is brought up under the shadow of a great city. The following fragment, taken from a recent address made in Middletown by General Ben. Butler, is opportune at this moment, and should be read carefully by every boy who is looking forward to the time when he will have chances to make his own opportunities in the great world outside the narrow limits of his old home:

"I have made my own way in the world. Why? Because as a boy I had time to reflect and think, and when I came to a city at the age of ten years, I have a right to say that I was as far advanced in my studies and in the knowledge of what I had studied as though I had been kept at work all the time at school. Who is the Speaker of your House of Representatives? Another man born, as I was, on a farm in New Hampshire. Who is the Mayor of Boston? He was born within six miles on a rockier farm than mine, if possible. I give you this advice of an old man who is passing away, and whatever may be its mistakes, it has no mistake in sincerity and earnestness. And, again, I say now as I began, that the wealth, the prosperity, the steadfastness, the hope of religion, of liberty and of freedom to the world, rests on the producing and on the country population of this Commonwealth and on that of the United States."

We have often spoken in these columns concerning the nauseous literature that falls into the hands of the average American lad, but it must not be supposed, that because we have not warned parents against the unwholesome reading that so plentifully finds its way into the hands of our girls, that we were not alive to the fact, that thousands of the future mothers of coming generations, are daily allowed to dawdle away their time, health and refinement, in poring over badly written soul-destroying novels.

It is very unusual to find a mother who is indifferent to her daughter's clothes. Practical-minded women will, even in spite of girlish remonstrance, insist on low heels, loose clothes, and warm wraps, and with wise saws and hygienic maxims crush the fashionable yearnings of budding womanhood for French heels, a genteel waist and sleeveless jackets.

But what can be said about the endeavor to provide for our daughters' mental nourishment and intellectual adornments?

There is no more amazing phase of nineteenth-century feminine development than its passionate and enervating indulgence in nauseous mental pabulum, and the appalling extent to which an unlimited supply of such stuff is furnished to the young. The same woman who is conscientiously careful of the school-companionship of her daughter of twelve or fourteen years is apparently criminally indifferent to the character of her associates in the world of books. She will watch what boy carries her girl's books home from school, but forgets to look below the cover of the new novel that same daughter has brought back from the circulating library, stopping there for it on the way home.

Now this apathy or ignorance in regard to what young girls read is responsible for the destruction of the finer tone of character of many of our children developing into womanhood, and explains a great deal of the frivolity, demoralizing coquetry and unfortunate 'affairs' which from time to time startle the community and bring sorrow and disgrace on highly respectable families.

No girl in her teens should be permitted to read a novel that has not first been read by some matured member of her family, or by some friend whose judgment is above reproach. If the book is such as may be trusted in the hands of a young girl, her friends will not hesitate to let her have it; if not, she will not desire to read it.

The resolutions lately passed by the New York Presbyterian Synod, in relation to the Roman Catholic Church, are both interesting and significant. The Synod congratulates the Roman Catholic province of New York upon the clerical supervision of its children, and the pains taken to guard them from the influence of pernicious literature.

This is right, and just, and only goes to prove the wisdom of the Roman Church, in preventing its children's minds from being poisoned at the most impressional age. Still it would have evidenced more wisdom on the part of the church if it had suggested—by name—the kind of literature of a secular sort, that, in the opinions of its fathers, would be the best for its children to read, for they will read, and if so, why not the YOUNG SCIENTIST?

It will be seen that we have introduced a "guessing department" this month, and one which we intend to continue from time to time in future issues. We should like very much if our younger readers would take "hold" strongly in this department, and send us matters for "guessing on," with the necessary answers. The "puzzles" will be given one month, and the answers thereto are expected to follow the succeeding month.

While it is not wise to make too many promises, yet it is sometimes necessary for the conductors of a journal like the YOUNG SCIENTIST, to give their readers an idea of what they may expect during the coming year; and, taking this view of the matter, it may not be out of place to say that in addition to the departments now in the journal, it is intended to add two or three others, including AQUATIC SPORTS, SCHOOL GAMES, the raising and manage-

ment of Pets, Poultry, and Bees, for all which we have secured assistance from specially competent contributors. These additions are to be made without trenching on the space now allotted to "Amateur Arts" and "Scientific Matters." Indeed, these departments will be improved in several particulars, and we can fairly promise that the volume for 1884 will outdo any of its predecessors in interest and usefulness.

Out of 780 young men under 21 years of age committed to the Eastern Pennsylvania Penitentiary during one year, 765 had no trades, though 772 were graduates of schools. This is a sad commentary on the too prevalent notion both of youths and parents that the only respectability and all the opportunities for individual advancement are in the kid-gloved pursuits. Young men roughly jostled out of the overcrowded professions and genteel employments find themselves utterly unfit for anything useful, and in too many cases turn to crime as likely to afford the most satisfactory returns. It is not the fault of education; it is the fault of the unfortunate social tendency of the times, which so seriously discriminates against legitimate labor, and falsely elevates white hands and good clothes and empty heads and pockets.

Another thing in connection with this matter, was the fact, that a majority of the 772 school graduates had been in their boyish days, readers of the villianous literature that is so prevalent and cheap, and not one of them had been provided with the YOUNG SCIENTIST or similar journals, by their parents. Had these boys been regular readers of "ours," they would not now have been living at the expense of the State of Pennsylvania. When will parents ever learn to provide their children with proper mental pabulum?

A number of leading ornithologists met in the American Museum of Natural History, New York, on September 26th, for the purpose of organizing a national association. Dr. Elliott Coues was elected chairman, and Mr. E. P. Bicknell secretary. The organization then adopted as its name The American Ornithological Union. A constitution which was adopted set forth the objects of the union, the principal objects being to further ornithological science and to revise the names and reclassify the list of North American birds. James A. Allen, of Cambridge, Mass., was elected President, Dr. Elliott Coues and Mr. R. Ridgeway vice-presidents, and Dr. C. Hart Merriam secretary. The society provided that there should be annual meetings. The number of active members was limited to fifty, and of foreign members to twenty-five, while no limit was fixed as to corresponding members.

The following gentlemen were elected to active membership:—C. Aldrich, Iowa; C. F. Bachelor, Massachusetts; C. E. Bendine, Oregon; E. P. Bicknell, New York; William Brewster, Massachusetts; M. Chamberlain, New Brunswick; C. B. Cory, Massachusetts; E. Coues, District of Columbia; D. G. Elliott, Long Island; A. K. Fisher, New York; J. B. Holden, New York; T. McIlwrath, Canada; C. H. Merriam, New York; E. A. Mearns, New York; D. W. Prentiss, Washington; R. Ridgeway, District of Columbia; R. W. Shufeldt, Louisiana; N. C. Brown, Maine; Professor S. F. Baird and J. A. Allen, Cambridge, Mass.

Athletic Notes.

Base-Ball.

THE DETROITS defeated the Eclipse Club, Oct. 8th, in Louisville, Ky., by 6 to 5.

THE PROVIDENCE CLUB missed a train and failed to appear, Oct. 6th, in Wheeling, W. Va., where they were booked to play the Toledo team.

THE HARVARD CLUB's receipts this season to Oct. 1st amounted to $4,609, and their expenses to $4,553. This leaves but a small balance on hand.

JOEL SAMSON, while engaged Oct. 5th in a game in the neighborhood of Elkhart, Ind., was hit in the temple by the ball, and died the same evening from its effects.

A GAME was played Oct. 6th, in Peoria, Ill., between the local professionals and the Allegheny. The visitors, who won by 12 to 7, were on their way home from

Omaha, Neb., where they had recently defeated the Union Pacific Club by scores of 6 to 2 and 10 to 7.

THE NEW CLUB of the Union League from Brooklyn will put a strong team in the field next season. They have already signed four players, and have several on trial. Their grounds will be located in the Eastern District, about twenty-five minutes' ride from Grand street or Broadway ferry.

METROPOLITAN *vs.* PROVIDENCE.—The first game this season between the above-named clubs was played Oct. 3d at the Polo Grounds in the presence of a large assemblage, and resulted in a well-earned victory for the Metropolitans, although they were weakened by the unavoidable absence of Holbert, Kennedy and O'Rourke. A wild throw by Esterbrook and a fumble by Roseman gave the visitors one run in the first inning. Radbourn, who was left after making a three-bagger in the first, got in a run in the fourth inning, when he was helped home by a passed ball and a wild pitch. The Mets earned two runs on two-baggers by Orr and Roseman, and singles by Keefe and Nelson, and obtained the winning run on errors by Erwin, Radbourn and Sweeny. Joe Start gave way to Sweeny in the third inning. The umpire seemingly favored the visitors, especially in calling balls and strikes. Keefe's effective pitching was the chief feature of the contest.

These two clubs contended again, with a similar result, on the Polo Grounds, Oct. 4th, when the attendance was small, owing to the cold weather. The visitors led off with five unearned runs in the first inning, although Lynch was batted but twice safely. Keefe then exchanged positions with Lynch, and, being better supported in the field, held the Providence down to one additional run, which was scored in the fourth inning on a two-bagger by Hines and a muff by Orr. The Mets made seven runs on four safe hits, together with bases on balls given Nelson, Brady and Crane, and four costly errors by Nava. The game was called on account of darkness in the seventh inning.

ATHLETIC *vs.* CLEVELAND.—The initial contest between the above-named clubs took place Oct. 4th, in Philadelphia, Pa., and proved to be an exciting struggle for superiority. Jones and Sawyer pitched for their respective clubs, the former proving the more effective. The Clevelands won by their superior fielding and timely hitting. Twice during the game the Athletics had three men on bases, and on both occasions they got runs in, but in each of these innings two men were left on bases, when one good hit would have decided the contest in their favor. It was too cold for sharp fielding. Evans and Bushong were injured early in the game, and gave way to Geer and McCormick. Blakiston played with the Athletics in the absence of Stovey.

ATHLETIC *vs.* PROVIDENCE.—The above-named clubs met for the first time this season Oct. 5th, in Philadelphia, Pa., the American Association champions then sustaining their most humiliating defeat of the season in the presence of about two thousand people. Radbourn retired the champions for no runs, and only three scattering safe hits, while seven of them struck out off him. Mathews was batted with ease by the visitors, Carroll leading with four safe hits, including two three-baggers. The visitors fielded sharply throughout. Two liners caught by Stovey, on one of which he made a double play, and a difficult running catch by Birchall were the redeeming features of the Athletics' play.

BALTIMORE *vs.* DETROIT.—The above-named clubs contended Oct. 4th in Baltimore, Md. Darkness obliged the umpire to call the game at the end of the eighth inning, when the score stood tied. Manning caught remarkably well and did the best batting of the game.

ATHLETIC *vs.* PHILADELPHIA.—The above-named clubs contended Oct. 3d on the grounds at Twenty-sixth and Jefferson streets, in Philadelphia, Pa., it being the seventh and deciding game of the series for the local championship. Between five and six thousand people were present, and the Athletics' share of the proceeds went to their players. During the first part of the game Stovey was presented with a silver-mounted rosewood bat and a silver base-ball, Stricker received a gold watch, and Bradley and Blakiston each came in for handsome badges. Bradley was too much for the Philadelphias, who made only one safe hit, while Purcell was batted freely by the Athletics. Stovey made his twentieth home-run of the season by a long hit over the left-field fence in the seventh inning. The Athletics won easily, outplaying their opponents at all points. The game was called on account of darkness at the close of the seventh inning.

These clubs met again at the same grounds, on Oct. 8th, when the Philadelphias secured their fourth victory of the series by a lucky streak of batting in one inning. The Athletics led up to the end of the fifth inning, having then scored four runs off five safe hits. The Philadelphias pounded Bradley in the sixth inning for six safe hits, including a three-bagger by Harbidge, and scored five earned runs. A single by Warner, a

two-bagger by Coleman, and a bad miss by Bradley, helped the Philadelphias to two more runs in the eighth inning. Stricker's second-base play was the fielding feature. Only one safe hit was made off Bradley in the first five innings, and off Coleman in the last six.

BOSTON *vs.* METROPOLITANS.—The fourth game of the series between the Boston and Metropolitan clubs—three of which were played last April—took place at the Polo Grounds, Oct. 6th, before a good crowd, though it was bad weather, rain falling during most of the game. Lynch was in the Metropolitan "box," and he troubled the visitors considerably. In fact, with as good support in all the positions as he had in most of them, the victory for the Bostons would have been doubtful. As it was, they did not earn a run off his pitching. The Mets found Whitney's pitching hard to hit, though Keefe and Nelson got an earned run from it by a three-base hit and a single, but no one else scored even a single hit. Crane's errors at second base were costly.

These clubs met again at the Polo Grounds on Oct. 8th, and, the weather being fine, there was a good attendance. The champions put in Buffinton to pitch, and he proved even more troublesome to the home batsmen than did Whitney, while the Bostons hit Keefe for an earned run this time. Gunning caught finely for the Bostons up to the eighth inning, when he injured a finger and had to give place to Hackett.

The last game the Boston champions played in this city was that of Oct. 9th at the Polo Grounds, when they sustained their first defeat at the hands of an American team, the Mets "Chicagoing" the visitors handsome by 1 to 0. A costly wild pitch gave the winning run to the home-team. The visitors got in only three hits off Lynch's pitching, and the Mets only four off Whitney's. Brady's outfield play was the feature of the Metropolitan fielding.

BOSTON *vs.* STATEN ISLAND.—The Boston team put in a first appearance in this vicinity since winning the championship Oct. 5th, when they played an exhibition game with the amateur nine of the Staten Island Club on the latter's ground. It was the fourth and last game of the series the Staten Island nine have played with the League teams. The Boston team included Gunning, who has been playing in the Northwestern League this season. He is originally from Fall River, and is evidently a good player. He caught Buffinton's difficult pitching very creditably indeed, putting out nine players, assisting four times, and having but one passed ball charged against him. Annis, late of the Anthracites, too, was in the team, Burdock not playing on account of a lame arm, while Hines was assigned to duty as umpire, which he attended to until struck in the face by a foul ball, when Burdock took his place. The Bostons had little difficulty in batting Tyng's pitching. Tyng was finely supported behind the bat by Laughran, who caught his pitching for the first time. The Islanders could do nothing with Buffinton's delivery, which was very effective. A very cool reception was accorded the champions by the small crowd of people present.

CINCINNATI *vs.* CHICAGO.—The above-named clubs—ex-champions of the American Association and League respectively—played a series of games last week in Cincinnati, O. The opening contest took place Oct. 1st, and resulted in a decisive victory for the Chicagos. Home-runs were made by Dalrymple and Gore, the latter, however, being decided out for failing to touch third base. The errors made by the Cincinnatis were very costly. Goldsmith was effective, holding the home-team down to five hits and striking out nine men. Errors by Pfeffer and Anson gave the Cincinnatis their only run. The attendance was good, although the weather was unfavorable.

ST. LOUIS *vs.* CHICAGO.—Fully four thousand people witnessed the first game this season between the Chicagos and St. Louis Clubs, which took place Oct. 5th in St. Louis, Mo. The visitors were aided very materially by close decisions in their favor.

The Chicagos defeated the St. Louis, Oct. 6th, by bunching their hits in the first and sixth innings. The winners made only four safe hits off Mullane, and thirteen of their men went out on strikes, while the St. Louis made ten hits off Goldsmith and only one struck out.

PHILADELPHIA *vs.* TRENTON.—The second game between the above-named clubs was played Oct. 5th in Trenton, N. J. The first game had terminated in favor of the Trenton team by a score of 15 to 14, and the present game was also closely contested. The home-team started off with the lead, and after losing it in the eighth inning got in the run that tied their opponents' score in the ninth. Darkness caused the umpire to call the game at the end of the tenth inning.

NEW YORK *vs.* CINCINNATI.—The above-named clubs played for the first time Oct. 6th, in Cincinnati, O., the games scheduled for the two preceding days having been postponed on account of rain. The visitors won with ease, a result mainly due to the excellent batting and base-running of Ward, who made three of the five runs credited to his club. The Cin-

cinnatis earned their only run on a two-baser by Mountjoy and a single by Carpenter. Troy's second-base play was the fielding feature.

CLEVELAND *vs.* QUICKSTEP.—The above-named clubs had a close and exciting contest together Oct. 3d in Wilmington, Del. The lead alternated until the ninth inning, when the Clevelands managed to secure the winning run.

ST. LOUIS *vs.* INDIANAPOLIS.—The St. Louis defeated the Indianapolis Club Oct. 2d in St. Louis, Mo., after an exciting contest of ten innings. The home-team took the lead in the first inning and held it up to the ninth, when the visitors managed to tie the score. Safe hits by Strief and Mullane allowed the St. Louis to make the winning run in the tenth inning.

ST. LOUIS *vs.* ALLEGHENY.—An exhibition game between the above-named clubs was played Oct. 7th in St. Louis, Mo. Davis, of Lynn, Mass., made his first appearance with the home-team and showed up well in the pitcher's position. Tom Mansell was credited with four safe hits off Bar, including a home-run. At the close of the game there was a foot-race of one hundred yards between Walter Latham and Mike Mansell, to decide the long-mooted question of superiority in running. Latham won easily.

ST. LOUIS *vs.* NEW YORK.—The New Yorks visited St. Louis, Mo., Oct. 8th, when they were defeated by the home-team's superior batting. Welch commenced pitching, but was knocked out of his position, and gave way to Ward. Latham's batting was the chief feature.

TOLEDO *vs.* CINCINNATI.—The Toledo team—champions of the Northwestern League—made their first appearance in Cincinnati, O., Oct. 7th, when they defeated the local club after an exciting struggle. The visitors did the best batting, Walker—their clever colored catcher—leading in that respect. A brilliant triple-play, accomplished by Welch, Barkley and Andrews in the fourth inning, was the feature of the contest.

Odd Notes.

—At the Tennis tournament held at Camp Washington, Staten Island, Oct. 3d, 4th, and 5th, by the Ladies' Club for Out-door Sports, the prize for the ladies' singles was won by Miss Goodwin of the Franklin (N. J.) Archery Club, defeating Miss Robinson, New Brighton Club, by 6-2 and 6-5, the latter securing one game by 6-4. The ladies and gentlemen's doubles were won by Miss Goodwin and Mr. Greenough, defeating Miss Ward and Mr. Shippen by 6-2 and 6-3.

—The senior tennis tournament at Yale College resulted as follows: Jenks first, Doolittle and Sheton second. In the freshmen tournament Haven was first and Thomas second.

—The Harvard Tennis Association on Oct. 2d held an election, resulting as follows: President, G. R. Agassiz, '84; vice-president, H. A. Taylor, '86; secretary and treasurer, G. W. Hoyt, '85; stewards, A. Curtis, '84; Pierson, '85; Minot, '86; and Kuh, '87.

—A novel race between a pigeon and a pony has just taken place at Bedworth, Eng., the former flying a mile and the latter galloping half a mile. A capital start was made, the starter standing half-way between the pigeon and the pony, and after a most exciting race the bird won by eighty yards.

—Says *The Sportsman* of London, Eng.: "Alfred Nixon, champion of the London Tricycle Club, who last year made the first and at present only tricycle journey from John o' Groat's to the Land's End, a distance of 1,007 miles in a fortnight, has just accomplished a ride of 750 miles, also for the first time on a tricycle, in 8 days 23 hours. Nixon left the Bank of England, London, on Wednesday, Sept. 12th, at twelve o'clock, and reached John o' Groat's House, Caithnesshire, Scotland, on Friday, 21st, at 11 A.M."

—The Somerville High-school eleven gave the Tufts College eleven an unexpected drubbing in a game of football on the college grounds at Medford, Mass., on Saturday, Oct. 6th. The Somerville boys were small and light, and therefore the collegians thought little of them, but were defeated by two goals and three touchdowns to one safety touchdown for Tufts.

—The Northside A. C. at a meeting held Oct. 4th elected the following officers: President, Thos. Moran; vice-president, Chas. Hamilton; treasurer, Harry B. Woods; secretary, Harry Kirby; captain, Wm. H. Fales; first lieutenant, Thos. Smith Sr.; second lieutenant, John F. Kirby.

—A match at football was played at New Haven, Ct., Oct. 6th, between the Yale College and Stevens' Institute football teams. The former won by a score of six goals and seven touchdowns to three safety touchdowns.

—The leading football clubs of Montreal, Canada, kicked leather for the possession of the champion cup on Sept. 29th. The weather was pleasant though cool, the gathering of spectators large, and the grounds were in capital order. The contest was a splendid one, both teams doing fine work, the play of the

Lousons, the Campbells, Fisher, Henneker and Hamilton being particularly noticeable on the side of the Montrealers, while for the Britannias McLeod, Myles, Blaiklock, Patterson and McLennan deserve special mention. The first game was won for the Britannias by Blaiklock, while Hamilton secured the two following games for the Montreals, who thus maintained their claim to the champion trophy, which they took from the Britannias in May last, after having lost it to them on Nov. 5th, 1881. The teams were as follow: Montreal—R. T. Henneker, E. H. Hamilton, E. W. Wand, A. Parry, A. E. Abbott, R. Stirling, S. P. Buchanan, J. N. Fulton, G. W. Cains, F. W. Cains, R. Campbell, A. J. Campbell, W. S. Louson, J. Louson, S. Fisher. Britannia—J. G. Ross, R. Kinghorn, S. M. Blaiklock, K. Young, J. W. McLennan, S. Campbell, J. J. Arnton, J. W. Cook, W. A. Munn, F. Scott, A. Woods, P. Myles, J. G. Writchener, J. Patterson, D. McLeod. Robert Esdaile was umpire for the Montreals, and R. D. McGibbon for the Britannias, while the position of referee was intelligently filled by R. W. Boodle.

Our Book Table.

Workshop Receipts, for the Use of Manufacturers, Mechanics, and Scientific Amateurs. Second Series. By Robert Haldane. London and New York: E. & F. N. Spon.

The first series of this work was devoted largely to such subjects as wood working and polishing, metallurgy, the working of different materials, and other matters of that kind. The volume before us treats more immediately of subjects which are specially related to chemistry, and although some of the topics that were discussed in the first series also appear in the present work, yet from the fact that they are handled in a much more complete and thorough manner, and embody the most recent information, the book may be regarded as entirely new.

The principal subjects which occupy a place in this volume are: Bleaching, Boiler Incrustations, Cements and Lutes, Cleansing, Confectionery, Disinfectants, Dyeing, Essences, Extracts, Fireproofing, Glue, Glycerine, Ink, Leather, Matches, Pigments, together with about twice as many more, which we have not room to cite.

All the articles show, on careful examination, that the author has brought his work down to the date of going to press—giving the best and most recent information in each case. Judging by those articles with which we are specially familiar, we find that the author has not contented himself with mere "scissors" work, but has carefully revised the receipts and processes given. The book is certainly one of great value.

Old Italian Embroidery. By Franz Lipperheide, 38 W. Potsdam Street, Berlin, Germany. Published in 2 volumes.

The volumes contain some fifty-six plates of fac-simile designs of old work. The plates themselves are works of art, being fine and clear engravings of high merit. Besides the plates, which contain several hundred embroidery designs, the work is finely illustrated, with engravings, showing the method of forming the "stitch" for the performance of the work exhibited, which is on a new plan invented by the author, and which shows the work finished alike on both sides of the material.

The explanations and instructions are written in German, and to those who are conversant with that language, the text will prove simple and easy to understand. The designs are copied from work executed during the 14th, 15th and 16th centuries, examples of which are preserved in the European museums. A large number of the designs were obtained from the Berlin Museum through the kindness of the director, Dr. Julius Lessing.

Full particulars of the work may be obtained by addressing the editor, as above.

American Newspaper Annual. Philadelphia: N. W. Ayer & Son.

This is a portly octavo volume, containing a list of *all* the newspapers and other periodicals issued in the United States and Canada. It gives the year when each journal was established, its size, circulation and general characteristics. In addition to this, it gives the population and other facts in regard to the towns and cities where the different journals are published, so that it forms an exceedingly useful gazetteer. The work seems to have been prepared with great care and accuracy, and must prove of great value to publishers, advertisers, and students who desire to know just what journals are published in their own departments. The advantages which it presents in the latter direction should insure the presence of one copy in every public library.

Astronomy for Amateurs.—November.

BY BERLIN H. WRIGHT.

THE PLANETS.—NOVEMBER, 1883.

(All Computations are for the Latitude and Meridian of New York City.)

Venus.—But few glimpses of Venus will be had this month, as she sets only about one-half hour after the Sun, as follows:

November	10th—5	22	evening.
"	20th—5	25	"
"	30th—5	35	"

She is moving eastward at the rate of about one degree a day, and at the close of the month will be upon the western margin of the Galaxy

close to the Milk-Maid's Dipper. She crosses the earth's path on the 8th, after which time she will be south of the Ecliptic. A telescope will show her with flattened sides or a gibbous phase.

Mars reaches his western quadrature Nov. 1st, and becomes an evening star upon that date, and will attract much attention from his situation, being almost within the Sickle in Leo. Regulus, at the end of the handle of the Sickle being a few degrees east of him. He rises as follows:

November 10th—10 35 evening.
" 20th—10 12 "
" 30th— 9 47 "

Jupiter is bowling along slowly after Mars, the distance between them gradually increasing. Jupiter rises as follows:

November 10th—9 55 evening.
" 20th—9 17 "
" 30th—8 37 "

The Moon passes 5° south of him on the 19th, and on the 21st he is stationary near the cluster Præsepe in Cancer. The following are the principal events transpiring with his satellites in the earlier part of the nights of November:

Nov. 6th—11 26 eve.,	Occultation.—	Reap.	(I.)
" 8th—11 8 eve.,	Eclipse.	"	(III.)
" 15th—11 47 eve.,	"	Dis.	(III.
" 21st—10 3 eve.,	Transit.	Ing.	(I.)
" 21st—11 13 eve.,	" (shad.)	Eg.	(I.)
" 22d— 0 23 mor.,	"	Eg.	(I.)
" 22d—11 25 eve.,	"	Ing.	(II.)
" 26th—10 8 eve.,	"	"	(III.)
" 29th—11 22 eve.,	Occultation,	Reap.	(I.)

Saturn will be brightest Nov. 28th, being at that time in opposition to the Sun, rising at sunset, and passing the meridian at midnight. He will be in conjunction with Aldebaran on the 2d, being $3\frac{1}{2}$° north of the star, and on the 15th in conjunction with the Moon, being only 1° north of that luminary. He passes the meridian as follows:

November 10th— 1 11 morning.
" 20th— 0 28 "
" 30th—11 41 evening.

Neptune also reaches his opposition this month on the 12th, passing the meridian on the 30th at 10.30 P.M.

NOVEMBER METEORS.

The two great meteoric epochs of November are Nov. 11th-15th, and Nov. 24th-Dec. 7th, the former called the Leonids and radiating from the Sickle in Leo. The maximum of this group is reached on the 13th. The last great display of these was in 1866. The Andromedes II. is the other great meteoric group encountered by the earth in November, radiating from near Almaach, the 2d mag. star in the left foot of Andromeda; the maximum is reached on the 27th, and the last great display was in 1872. Other minor groups prevail as follows: The Leonimoroids, from the compact cluster of stars in Leo Minor—Nov. 25th-28th; also on same date a swift group describing short arcs from near the star in the end of the handle of the Great Dipper in Ursa Major. The Geminids are met with Nov. 27th, radiating from near Castor; a very rich group, continuing during most of December, reaching its maximum Dec. 10th-11th.

EPHEMERIDES OF THE PRINCIPAL STARS AND CLUSTERS, NOV. 21ST, 1883.

	H.	*M.*	
Alpha Andromeda (Alpheratz) in meridian	8	4	eve.
Omicron Ceti (Mira) variable, in meridian	10	15	"
Beta Persei (Algol) variable, in meridian	11	2	"
Eta Tauri ("Seven Stars" or Pleiades) in meridian	11	42	"
Alpha Tauri (Aldebaran) in merid.	0	34	mor.
Alpha Aurigæ (Capella) in merid.	1	13	"
Beta Orionis (Rigel) in merid.	1	14	"
Alpha Orionis (Betelguese) in merid.	1	54	"
Alpha Canis Majoris (Sirius or Dog Star) rises	9	41	eve.
Alpha Canis Minoris (Procyon) rises	9	16	"
Alpha Leonis (Regulus) rises	11	19	"
Alpha Virginis (Spica) rises	4	0	mor.
Alpha Bootis (Arcturus) rises	3	3	"
Alpha Scorpionis (Antares) invisible.			
Alpha Lyrae (Vega) sets	11	28	eve.
Alpha Aquillae (Altair) sets	10	16	"
Alpha Cygni (Deneb) "	2	37	mor.
Alpha Pisces Australis (Fomalhaut) sets	10	52	eve.

De Land, Florida.

Origin of Postage Stamps.

It is generally believed that postage stamps are of quite modern origin. This is an error, for we find from the current number of the Bulletin de l'Imprimerie et de la Librarie that the first collector of postage stamps lived in the reign of Louis XIV. During the seventeenth century, when the King changed the place of residence for the court, persons in his suite procured tickets which they stuck on letters intended for Paris, in order that they might be received and forwarded by his majesty's carriers. M. Fenillet de Conches, a collector, possesses a letter directed to Paris foi Mlle. de Scudery by Pelisson Fontamer, on which is found a kind of postage stamp. In 1654 a regulation was issued to the effect that

persons writing from one part of Paris to the other might have their letters, etc., faithfully carried and diligently delivered to any address, provided they attached to their letters a ticket indicating that its carriage was paid, as money would not be directly accepted. This ticket might be attached to or placed around the letter, or affixed in any convenient manner so that it be plainly visible. The price of this pre-paid ticket was a sou. The system had been in force since August, 1633.

A Large Object-Glass.

The object glass for the great refracting telescope intended for the Russian observatory of Pulkowa, has been finished by the Messrs. Clark, of Cambridge, Mass., and is the largest glass thus far constructed. The order for the glass was given in 1881 by Prof. Struve, the director of the observatory, who has lately visited this country for the purpose of subjecting the glass to certain tests of its quality. These, it is said, proved to be in every way satisfactory, and the object glass is by this time on its way to its ultimate destination, if, indeed, it has not already arrived there. This great object glass is thirty inches in diameter. Pulkowa, however, will not be able to claim very long the distinction of having the largest refracting telescope in the world, for the great Lick telescope for California will have an object glass of thirty-six inches diameter, or six inches greater. Six inches appears a small addition, but it represents an enormous increase in power, for the light-gathering area of the Lick object-glass will be to that of Pulkowa as 1,296 to 900, or forty per cent. greater. The rough disk of the flint portion of the Lick glass has already been received by the Clarks, and they are at work upon it. It will be several years before it is finished.

Advances in Scientific Discovery.

The opinion is commonly expressed by those who are not well informed, that the world is so rapidly advancing in scientific discovery that a few years more of such extraordinary advancement as we have witnessed during the past quarter of a century, will practically exhaust the sources of discovery, and the scientist will sigh in vain for "for new worlds to conquer." No opinion could, in reality, be more delusive than this. Each fresh discovery which discloses a secret that nature has so long and carefully guarded, illuminates with its feeble rays a background of other mysteries still unsolved, and so far from narrowing the field of discovery, widens the circle of the unknown and places its horizon still further off. He who thinks he has mastered a science is a superficial thinker. The profound thinker is he, who, having possessed himself of all the knowledge of his predecessors, perceives how little the sum of that knowledge is, in comparison with what still remains to be learned.

Scientific News.

—There is a curious clock in Japan. This clock, in a frame three feet high and five long, represented a noon landscape of great lovliness. In the foreground were plum and cherry trees and rich plants in full bloom; in the rear, a hill gradual in ascent, from which flowed a cascade admirably imitated in crystal. From this a thread-like stream glided along, encircling in its winding rocks and tiny islands, but presently losing itself in a far-off stretch of woodland. In the sky turned a golden sun, indicating as it passed the striking hours, which were all marked on the scale below, where a slowly creeping tortoise served as a hand. A bird of exquisite plumage, resting by its wings, proclaimed the expiration of each hour. When the song ceased a mouse sprang from a grotto near by, and, running over the hill, hastily disappeared.

—"C. S.," says an *Exchange*, "asks the origin of the belief or superstition that it was fortunate for any one to find a horse-shoe and that nailing it over one's door or hanging it in the house would bring good luck. The English antiquary, John Aubrey, who wrote about the middle of the seventeenth century, says that in his time most of the houses in the West End of London were protected against witches and evil spirits by having horse-shoes fastened to them in various ways. It was the belief that then no witch or evil genius could cross the threshold which was protected by the shoe. The fact is that the superstition has been traced so far back, and then we lose it in the obscurity of the ages. The custom of nailing horse-shoes for luck to all kinds of sailing craft is still in vogue, and is religiously maintained to be a wise and lucky measure. The superstition goes further, by making it fortunate for any one to find a horse-shoe, and the good luck is increased with the number of nails that are attached to the shoe when it is picked up."

—Cros. Vergeraud has utilized the properties of bichromates to produce positives directly on paper. He first saturates a suitable kind of paper with a solution of 2 parts of bichromate of ammonia and 15 of glucose in 100 parts of water, dries it, and exposes it under any positive (either a glass transparency, a drawing, tracing or other flat object). As soon as the exposed parts turn gray, it is immersed in a bath consisting of one part of nitrate of silver and 10 of acetic acid in 100 parts of water. The picture makes its appearance at once, and is of a blood-red color (bichromate of silver). Wherever the light acts upon it, the glucose reduces the bichromate, but in those places which have been protected by the

drawing, etc., the bichromate will be unchanged, and hence capable of forming chromate of silver, which is insoluble in water, If dried by the fire, the picture will remain red; but if exposed to the sunlight, it becomes dark brown. Sulphuretted hydrogen, or a bath of potash and copper turns it black.—*Comptes Rendus.*

Practical Hints.

—A soft alloy, which attaches itself so firmly to the surface of metals, glass, and porcelain that it can be employed to solder articles that will not bear a very high temperature can, it is said, be made as follows: Copper dust obtained by precipitation from a solution of the sulphate by means of zinc is put in a cast-iron or porcelain-lined mortar and mixed with strong sulphuric acid, specific gravity 1.85. From 20 to 30 or 36 parts of the copper are taken, according to the hardness desired. To the cake formed of acid and copper there are added, under constant stirring, 70 parts of mercury. When well mixed the amalgam is carefully rinsed with warm water to remove all the acid, and then set aside to cool. In 10 or 12 hours it is hard enough to scratch tin. If it is to be used now, it must be heated so hot that when worked over and brayed in an iron mortar it becomes as soft as wax. In this ductile form it can be spread out on any surface, to which it adheres with great tenacity, when it gets cold and hard.

—A man can always learn something if he will only look about him. I was at the Postoffice Department the other day, says an observer, and I noticed an employee busy affixing stamps to envelopes. Every time he moistened the right hand corner of the envelope and then placed the stamp upon it. I asked him if there was any advantage in wetting the envelope instead of the stamp, and he said: "You notice that I moisten the envelope first; well I do that because it is the right way. There is a right and a wrong way to everything, and consequently there is a right and a wrong way to put on postage stamps. It is impossible to moisten a stamp with the tongue unless a small proportion of the gum adheres to it. Now this gum is by no means injurious, but then the department does not advertise it as a health food; so the only way left is the right way, and that is to moisten the envelope first." After listening to this brief statement I felt as though I had emerged from the deep shade of ignorance to the glorious sunlight of knowledge.

—Men, women and children require just so much sleep, and if they do not have it, suffer in consequence. I do not think a person should be waked in the morning, and for this reason, when a man falls asleep, he is in the shop for repairs, as the railroad men say. His frame and all its intricate machinery is being overhauled and made ready for the next day's work. The wear of the previous day is being repaired. Nature is doing that herself. She knows what the tired frame needs just as she knows how to make the heart throb and send the blood coursing through the veins. Then she takes that tired frame, lays it down on a bed, surrounds it with the refreshing air of night, covers it with the soft darkness, and lets the man rest. "Tired nature's sweet restorer, balmy sleep," visits him, and as the hours wear by, his energies are renewed, his strength comes back, and finally, when morning breaks and the sunlight steals through the lattice, he opens his eyes and is himself again. Or, if he is early to bed, he awakes with the cock's crowing. Now, who shall go to that man's side an hour before he opens his eyes, and say to nature, stand aside and let him get up; he has had enough of rest? Well, nature will say: "You can take him if you will, but I will charge him with an hour's loss of sleep, and I'll collect it out of his bones and nerves, and his hair and eyesight. You can't cheat me. I'll find property to levy on!"—*Journal of Health.*

Notes and Queries.

In continuing this department, which has been found of so much value, we would remind our readers who wish for information on any of the arts and sciences, that they are cordially invited to make their wants known through this column, and those of them who can furnish accurate answers to questions asked are requested to send in replies. Doubtless many of our subscribers may know of methods, processes, or devices that may be better or more suitable for the particular case in question than anything generally known, and it is this reason that induces us to keep this department open for a medium, where an interchange of ideas and practices may be made to the advantage of all our readers. Correspondents will please send their full address when forwarding their communications—either questions or answers—not for publication, unless expressly so stated, but so that we may know where to find the writer if desirable. Communications should be sent in on or before the first of each month previous to publication, to insure insertion in next issue.

Answers.

133. NEW HAMPSHIRE BOY.—Concrete is the best building material in the world. It is four times cheaper than wood, six times cheaper than stone, and superior to either. Proportions for mixing: to eight barrows of slaked lime, well deluged with water, add 15 barrows of sand; mix these to a creamy consistency, then add 60 barrows of coarse gravel, which must be worked well and completely; you can then throw stones into this mixture, of any shape or size, up to ten inches in diameter. Form moulds for the walls of the house by fixing boards horizontally against upright standards, which must be immovably braced, so that they will not yield to the immense pressure outwards as the material settles: set the standards in pairs around the building, where the walls are to stand, from six to eight feet apart, and so wide that the inner space shall form the thickness of the wall. Into the moulds thus formed throw in the concrete material as fast as you choose, and the more promiscuously the better. In a short time the gravel will get as hard as the solid rock.—RUBY.

134. WEATHERWISE.—There is no valid reason why you should not be able to construct a tolerably correct barometer if you follow the directions given herewith: Get a strong glass tube 34 inches long and of a smooth even bore. Close one end by means of a spirit lamp and blow

pipe, or Bunsen burner, and fill the tube with pure, clean, dry mercury, excluding all bubbles of air. Now place your finger over the open end of the tube, and cautiously insert it in a small cistern or vessel partially filled with mercury. Do not remove your finger until the end of the tube which it covers is safely below the surface of the mercury in the vessel. When the tube is thus inserted, remove your finger, and the contents will fall until the height of the mercury is nearly 30 ins. above the level of the mercury in the cistern beneath. In the barometer the mercury never rises above 31 inches, and seldom falls below 27. The tube may be fitted into a grooved wooden case, the scale attached in the proper place, and the final adjustment made by comparison with a correct instrument.—KINO.

135. F. K.—A beginner need not worry himself about the points of a violin. Learn to play first, and then, when you understand what you are about, go in for an "old master" if you please; but most of the merits of such instruments are imaginary, and the copies are just as good. In fact, nine-tenths of the Amatis, Stradivaris, Guarneris, and Bergonzis have been made in Paris, cooked in Brussels, and labelled in Lambeth, to be "picked up as bargains" in New York, Boston, or Philadelphia.—MUSIC.

136. PUZZLED.—To bore a hole through a glass plate, make your drill white-hot, and then plunge it into mercury. Use camphor dissolved in spirits of turpentine to lubricate with, and you will get through the glass as easily as through a piece of mahogany. There are several other ways to drill holes in glass, just as simple. See "Workshop Companion," price 35 cents.—OLD READER.

137. DAISY.—We cannot prescribe for your pet dog as we do not know its ailment. In asking us to prescribe a method of treatment for any pet animal, whether bird or beast, our readers would do well to mention how it has been fed. Feed your canary only on canary seed and rape, two parts of the former to one of the latter. Give three drops of castor-oil every week; put a rusty nail in the water for a fortnight, and annoint the naked parts once a day with pure salad-oil.

138. DAISY.—1. For dandruff get a pomade as follows:—Nitric oxide of mercury ointment, one part; ordinary pomade, four parts; rub in night and morning, not on the hair, but into the scalp; wash twice a week with carbolic soap; take a little sulphur internally three times a week, and, if the health be low, a course of iron and quinine. 2. Grease spots may be taken out by placing pieces of brown paper over them, and pressing with a hot iron as long as the bits of paper will absorb the grease. 3. Depends entirely on the kind of ink and color of cloth. Spirits of salt will remove some.

139. CYCLIST.—1. The earliest notice of velocipedes is said to be that by Blanchard on July 17, 1779. The first bicycle ever made and run successfully was invented and built by a Scotchman, Gavin Dalzell, of Desmahagow, in 1836. The indiarubber tyres were the invention of Mr. E. A. Cowper. 2. Plated machines are almost as difficult to keep properly clean as bright ones. 3. Keep a pin down the nozzle of your oil-can, and the aperture will always keep clear; but do not use oil, try glycerine instead.—BICYCLE.

140. FARMER BOY.—A horse will travel 400 yds. in 4½ minutes at a *walk*, 400 yds. in 2 minutes at a *trot*, and 400 yds. in 1 minute at a *gallop*. The usual work of a horse is taken at 22,500 lbs. raised 1 foot per minute, for 8 hours per day. A horse will *carry* 250 lbs. 25 miles per day of 8 hours. An average draught-horse will draw 1,600 lbs. 23 miles per day on a level road, weight of wagon included. The average weight of a horse is 1,000 lbs.; his strength is equal to that of 5 men. In a *horse mill* moving at 3 feet per second, track 25 feet diameter, he exerts with the machine the power of 4½ horses. The greatest amount a horse can pull in a horizontal line is 900 lbs.; but he can only do this momentarily, in continued exertion, probably half of this is the limit. He attains his growth in 5 years, will live 25; average, 16 years. A horse will live 25 days on water without solid food, 17 days without eating or drinking, but only 5 days on solid food without drinking.—JOCKEY.

141. LITTLE MAIDEN.—"The onyx stone, on which the most valuable cameos are cut, is found in such plenty on the Uruguay River in Brazil that ships often take it for ballast," said a cameo cutter. "Some of it has been found in Germany, where much of the cutting is done. The market is flooded with cheap and imperfect cameos, the work of apprentices, yet there is a fair demand for new work at good prices, especially for portraits. The art of cameo cutting is very old, and some of the specimens of Roman work done 2,000 years ago are exquisite in tracery and design. They are produced by an extraordinary amount of labor, unaided by the modern improvements in tools. Such work was then done for monarchs or very wealthy persons, and a cutting requiring a year was a very common thing. The same quality of work is now within the reach of persons of moderate means. Three fair looking cameo cuttings, suitable for mounting as breast pin and earrings may be bought for $8. But cameo portraits cost from $50 to $250, according to size, and the stone for the latter would be worth about $70.

"A raised cutting on any stone is called a cameo; when the device is sunk it is called an intaglio. The onyx is preferred for cameos above all stones, because it comes in layers of two colors. The combinations are black and white, black and cream, red and white, and dark brown, called the sardonyx. The advantage of a cameo portrait is that it will last forever. The stone is so hard that it can be cut only with diamond dust. The process of cutting consists of holding the stone up to revolving drills whose soft steel ends are covered with diamond dust. The utmost patience and caution, and delicate manipulation are required to grind off the upper layer of stone. A mistake is fatal to the work. No steel can be made hard enough to drill the onyx. Even chrome steel will not do it, and that is so hard that a drill made from it will cut through an ordinary file. No acid will affect the onyx, and it will stand the greatest heat of the furnace if the heat be applied gradually, so as to prevent cracking."—HISTORICUS.

142. Answer to Query No. 66, for May, 1883. How many times has the end of the world been predicted by men of more or less weight? Are there any such doleful predictions hanging over us now? If not too late to answer I offer this. It would be difficult to say just how many have predicted the "end of the world," but it is true that many have done so; some of them being sober, thoughtful men, and not to be condemned as fanatical, because others have been so wild in their prognostications, as to shoot very wide of the mark. Second, are there any such doleful predictions hanging over us now? Answer: Those who have any claim to be heard on the subject must give the Bible as their authority; therefore, the best way to state what *is* predicted will be What do the Scriptures teach? and from this we may judge whether what they foretell may properly be called "doleful." Take an instance. The subject is brought up in Matthew xxix., 3, where the disciples ask of Christ the direct question, What shall be the sign of the end of the world? and the mistake made by expounders is in the meaning they give to the word world. It is taken to mean the globe on which we dwell, hence all the *confusion*. Whereas its proper use is of the world at large; the course of this world, this dispensation, which is to have its end, or, as the actual meaning of the Greek is, "the end of the *age*." This world is never to end, and the Scriptures do not say so; but on the contrary de-

clare that it is to endure forever. Ecclesiastics i., 4, reads, "The earth abideth forever." Now, if *this age* is to end (even in a tragical way) to give place to a better, is that doleful? If sin is to be banished, and *earth* as well as man *redeemed*, is not such a consummation better than its destruction, and more desirable than its *present* condition? If Christ, in delivering the race of man from the power of his enemy, also buys the Home of man and gives it back to him as an eternal inheritance, is not that an issue worthy of the Lord of the whole Earth? That Redeemer who is to rule and reign over the earth which He has bought and owns as the "coming man," "the coming King?"—E. B., Rutherford, N. J.

Queries.

143. Gluing up Stuff.—I find a good deal of difficulty in gluing up joints. I can't make them stay together. Will some one give me a few hints regarding this kind of work.—Amateur.

144. Emblems.—Will some one who is posted inform me of what are the various emblems of "God and the Father," "The Holy Spirit," and the "Trinity," and greatly oblige—Episcopalian.

145. Guinea Pigs.—I would like a few hints as to the keeping and management of Guinea pigs, with a statement of what they should eat.—Kino.

146. Violin.—How many pieces are there in a violin, and where are they situated?—F. K., Danbury.

147. Dressed Skins.—Can squirrell skins be dressed at home sufficiently nice to be made into trimmings and muffs, or for lining for cloaks?—Katie B.

148. Broken Paintings.—I have two or three oil paintings on which I set a great value; on one of them the canvas has been broken a little. How can I repair it to make it look well.—Anxious.

149. Ebonizing Wood-Work.—Having made some nice wooden articles, after the designs and descriptions published in the Young Scientist, some time ago, I am anxious to have them ebonized nieely, and would be glad to have some information regarding the materials used for the purpose, and the mode of application.—Willing to Learn.

150. Impressions of Ferns.—I would like to take some impressions of ferns if any one will kindly inform me how the work is done.—Sadie.

151. Etching on Glass.—Any information on this subject will confer a favor on—Etching.

Market Report.

Retail Prices.

IMPORTED CAGE BIRDS.

Canaries, *Belgian*, per pair	$6.00 to 15.00
" *French*, per pair	6.00 to 15.00
" *German, Hartz Mts.*, each	2.50 to 10.00
Gold Finches, each	1.50
Gold Finch (mules), each	2.50 to 5.00
Bull Finches, not trained, each	2.50
Bull Finches, trained to sing two tunes, each	10.00 to 40.00
African Finches, per pair	2.50 to 5.00
Chaffinches, each	1.50
Talking Mino or Mina	10 00 to 25.00
Linnets, each	1.50 to 2.00
Linnets (mules), each	2.50 to 5.00
Green Linnets, each	1.50
Java Sparrows (blue), each	1.50
Java Sparrows (white), per pair	6.00 to 8.00
English Sparrows, per pair	1.00
Siskins, each	1.00
Gray Cardinal, each	4.00 to 5.00
Nightingales, each	8.00 to 25.00
Japanese Nightingales, each	5.00 to 10.00
Thrushes, each	5.00 to 7.00
Skylarks, each	5.00
Troopials, each	7.00 to 12.00
European blackbirds, each	5 00 to 7.00
Black-caps, each	4.00
Starlings, each	4.00 to 6.00

PARROTS.

Gray Parrot	10.00 to 15.00
Single Yellow-Head Parrot	8.00 to 12.00
Double Yellow-Head Parrot	10.00 to 15.00
West Indian "	4.00 to 5.00
Cockatoo (white)	18.00
Australian Shell Paraquets, per pair	6.00
"Love Birds," African Paraquets, per pair	6.00
West Indian Paraquets, per pair	3.00 to 5.00

All birds that are accomplished singers or talkers bring high and "fancy" prices. Parrots are rated by the number of words, sentences, and tunes they have learned.

AMERICAN CAGE BIRDS.

Canaries, each	2.50
Mocking Birds, females, each	1.00
" " singers	12.00 to 25.00
Robins	2.50 to 5.00
Blue Birds ("Blue Robins") each	1.50
Indigo Birds, each	1.00
Nonpariel, each	1.50 to 2.00
Virginia Cardinal, each	2.50 to 3.00
Bobolinks, each	1.50 to 2.00
Yellow Birds, each	1.50 to 2.00

Prices Paid by Dealers.

Roblns, per hundred	12.00
Biue Robins (Blue-Birds), per pair	0.35

For all information on this subject, as to reliable dealers, etc., etc., send postal card to YOUNG SCIENTIST. When desired, the goods can be sent through this office, but in all cases remittances must accompany the order.

EXCHANGES.

Only those who are *yearly* subscribers, and whose names are entered on our books have the privilege of inserting exchanges.

Exchanges must be on separate slips of paper or postal cards. If mixed with business matter in letters or cards they are filed away and never reach the printer.

Exchanges must not exceed thirty words.

Buying and selling belong to the advertising department.

We reserve the right to omit the exchange column, when we have not room for it, and the amount of space at our disposal will regulate the number of insertions given to each *exchange*, the preference being always given to those who have not previously used our columns.

A number of first-class tricks, trick books, stamps, coins, Confederate money, curiosities, etc., to exchange for stamps or pet stock, such as rabbits, Guinea pigs, or squirrels. J. S. Reese, 52 Cedar St., Canton, Ohio.

Shell boat, Spanish cedar, 28 feet long, spoon oars; good order; been used but little; for offers. J. W. B., Carmel, N. Y.

Rowing machine, cost $10; photographic outfit, $16; Flobert rifle, $15; medical battery, $10; "Wood's Botany," etc.; for elk horns, deer horns, minerals, Indian relics, and all kinds of curiosities; would like list of curiosities from dealers. Chas. C. Collier, 3617 Locust St., Philadelphia, Pa.

Vol. III. of the *American Machinist* for the best offer of minerals. J. A. S., P. O. Box 83, East New York.

I have five or six complete years of the *Galaxy* (magazine) also a number of odd copies: I will exchange the lot for an induction coil in good condition, and giving at least a ¼ in. spark. W. B. Greenleaf, 480 La Salle Ave., Chicago, Ill.

I have eighteen numbers of the *Harper's Young People* (79 to 96 inclusive), containing part of the story "Tim and Tip," by James Otis, and all of the story "The Cruise of the Ghost," to exchange for a good spyglass, a good bull's-eye lantern, or a small telephone. J. H. Gamsey, Box 25, Wilmington, Will. Co., Ill.

A good violin, bow, box, books, all complete, worth $12.00, to exchange for Wood's Botany, Young Mechanic, or scientific books and papers; send list. A. D. Chamberlain, Trout Creek, Del. Co., N. Y.

A model self-inking printing press, chase 2½ x 3¼, 4 fonts card type, 3 type cases, ink, roller and furniture all in good order, to exchange for a good silver watch and nice chain. G. E. Wilmot, Box 88, Lebanon, N. H.

Any person wishing to exchange foreign stamps please send sheet and I will return it with mine. Box 90, Melrose, Mass.

New Nickels (without "cents") for offers; I also wish to exchange with curiosity, coin and stamp collectors residing in foreign countries. G. S. Griffin, Moline, R. I. Co., Ills.

1 Sea bean, 1 alligator's tooth, 1 small cocoanut, 1 liver bean, lot of other beans and shells and 50 foreign stamps for printing press and outfit, size of chase about 6¼ x 4 inches; send postal. Geo. O. Riphard, Westminister, Md.

W. C. Roseboom, Cherry Valley, N. Y., wishes to exchange with amateur photographers, or others; photographs and pictures taken by themselves, mounted or unmounted; give name of picture and camera.

I would like to exchange minerals, stamps and curiosities for the same. O. J. Lache, 1313 Poplar St., Philadelphia, Pa.

6 fonts type, 4 cases, 2 composing sticks, leads, rule, etc., outfit except press, to exchange for good tent, not less than 6x6, or offers; send card before exchanging. Wm. O. Brown, Middlebury, Vt.

I have double barrel muzzle-loading shot gun, watch, orguinette, harmonica, stuffed birds for Household microscope, photo. outfit, books on natural history; specimens or offers. E. O. Tuttle, Bristol, Vt.

A printing-press, chase 5½ by 7 inches, in good order; will exchange for a large self-inking press or type. A. W. Barrett, Canajoharie, N. Y.

A one-keyed flute and pair of No. 10 club skates for rifle; E-flat cornet, cost $25, for an eight or six-keyed flute of equal value; all good; or offers. J. L. Pilkington, Pearsalls, L. I.

For fossils or minerals; fine specimens of Pentremites—two varieties—from sub. carb. rocks; also Flobert rifle, in good condition, and McKinnon pen. M. H. Crump, Bowling Green, Ky.

I have for exchange a collection of about 80 species of fine fossils, all named and making a fine collection, which I wish to exchange for opera glass, microscope, telescope, or offers; correspondence solicited. A. Stapleton, Box 756, Seneca Falls, N. Y.

Wanted, amethyst, moss agates, trilobites, geodes, coral, and coal ferns in exchange for fifty Indian arrowheads, coquina rock and Florida moss. E. V. Sheerar, Wellsville, N. Y.

"Crystallography" (40c.); "Electricity" (40c.); "Selection and Use of Microscope," abridged, (30c.) Either in exchange for "Workshop Companion," or two for "The Microscope," by Ross, or offers. C. H. Denniston, Pulteney, N. Y.

Home Medical Battery, cost $7; Lemair's Field-Glass, No. 2202 of Queen's Catalogue, cost $15.50; Achromatic Spy-Glass, power 25 times. To exchange for books or offers. Emerson Heilman, Heilmandale, Pa.

A small collection of coleoptera, comprising 100 species and 300 specimens, all correctly named, in exchange for bird-skins, insects, books, or eggs. Emil Laurent, 621 Marshall St., Phila., Pa.

A small magic lantern, Ruby pattern, with twelve slides, for a good book on Entomology, with illustrations. Willie R. Hotchkiss, Morrisdale Mines, Clearfield Co., Pa.

Wanted, Thompson's "Witchery of Archery." Must be in good condition. Write before you send. J. Anthony, Jr., Coleta, Whiteside Co., Illinois.

A telescope worth $3.50, for a self-inking printing-press and outfit; chase not less than 2½ by 3½ in. Eddie Judd, 260 Connecticut St., Buffalo, N.Y.

To exchange for offers: $20 scroll-saw, Seneca Falls make, $4 Bailey circular plane, set of Auburn metallic planes, brass-bound four-foot rule, fourfold, Traut's patent combined plow, dado, etc., cost $7. F. A. Rappleye, P.O. Box 12, Farmer Village, Seneca Co., N.Y.

Bee Hive wanted; one of the old-fashioned straw "skeps"; say what you would like in exchange. Apis, care of Young Scientist, 294 Broadway, N Y.

A first-class type writer, in excellent condition, cost $125.00, to exchange for good microscope, telescope, or valuable scientific books; send full particulars. A. B. Box 114, Lewiston, Maine.

A $30 stencil outfit (Spencer's) for a self-inking printing press in good condition, chase about 6 x 9; rich ores and minerals of Idaho for scientific and instructive books, printing press, type, etc. J. P. Clough, Junction, Lemhi Co., Idaho.

Wanted pyrites of iron from Colorado gold mines in exchange for sea shells and other gems; send list of what you have to exchange. S. Ferguson, Eureka Springs, Arkansas.

A banjo in good condition, two pairs of rosewood bones, three splendid games, and a fine set of drawing instruments, for a good cornet, viola, violincello or double bass. L. B. Hill, Kalamazoo, Mich.

Scientific specimens of various kinds for same. Geo. E. Frazier, Caldwell, Ohio.

Lester W. Mann, Randolph, Mass., Box 162, has Demas scroll saw, lathe and tools, emery wheel; $20 worth patterns; Smithograph; large harmonica, cost $1.75; novelties in seeds; for large self-inking press or offers.

10 volumes Chambers' Encyclopædia, American Book Exchange edition (cloth); Bonanza printing press, chase 3 x 5, card type, ink roller; spyglass, power 10 times; for French triplet, 1-5 in., or offers. H. P. Nichols, P. O. Address, Bridgeport, Conn.

A good telescope, also foot-lathe and saw combined, each worth $10.00, for shells, fossils or relics. Independent, Conncautville, Crawford Co., Pa.

Birds' eggs to exchange for others; send list of what you have to exchange. Emil Laurent, 621 Marshall St., Philadelphia, Pa.

Twelve or fifteen volumes of the American Agriculturist to exchange for scientific books or offers. W. H. Osborne, Chardon, Ohio.

Overglaze Painting on Porcelain.—IV.

BY AURELIO DE VEGA.

MEDIUMS.—30. These are requisites, and upon the kind used and upon their quality depends, to an extent greater than is generally supposed, the appearance of the finished work. The mediums are, as their other general name of vehicles indicates, the carriers of the paint, the means by which it may be spread.

31. *Unsatisfactory Mediums.*—Several things have been tried from time to time as vehicles, in fact, pretty well everything that, having some substance of its own and being adapted to be smoothly spread, would hold the pigment in suspension. Thus we find among those not unfavorably mentioned occasionally, glycerine, syrup of the "golden" variety, and gum. The thinning agent for use with these is water. Now, glycerine is a very good thing in its place, as, for instance, when used in moderation for keeping water color moist, or for chapped hands, but it is certainly not in its proper place when on the china painter's palette. Water, when mixed with glycerine or syrup, evaporates very slowly, and the painting would be constantly liable to be smudged. Moreover, the saccharine uncrystallizable portion of the medium would be very likely to boil up in the muffle. Gum, when dry, will, under heat, pulverize and mix with the paint, producing an unsatisfactory appearance. I recommend, therefore, that all such mediums as these be avoided.

32. *Satisfactory Mediums.*—The mediums which are in general use and give every satisfaction, are of two kinds—a spirit and an oil; the latter being the vehicle proper, the former the thinning agent to render practicable the spreading of the mixed oil and paint in a coat of any desired depth or thickness. The spirit and the oil are both either of turpentine or of tar—spirit and oil of turpentine be-

ing used together, and spirit and oil of tar.

(*a.*) *Turpentine.*—Ordinary spirit of turpentine is, I think, too well known to require description. It is procurable at any oil store at about 25 cents a gill in small quantities, and is what house painters use in mixing their oil colors. This kind is not, however, always to be recommended for painting purposes, as frequently it contains impurities, and has more or less of a tone or tint about it. The right kind for painting is the rectified spirit to be procured at an artist's material shop, where the price will probably be ten cents for a little bottle holding about two ounces. This spirit is as clear as the proverbial crystal, and as limpid as the purest water, and when fresh, is colorless and does not present the slightest trace of oil or water. This kind, and this only, should be used in painting. At the same time the common turpentine, when quite clear, and clean, and white, answers very well, as has been noticed in Sec. 28, for washing the brushes and palette with, and for removing paint from the palette knife, etc. The oil of turpentine is also known as fat oil. It is viscid, much of the consistency of golden syrup, and has something of the color of clouded amber. This may be purchased for 25 cents a small bottle, but it may also be prepared from turpentine by the amateur, thus:—Into a saucer—the flatter the better—pour a little spirit of turpentine, say from a dessert to a small tablespoonful, according to the size and flatness of the saucer, and over the saucer place a layer of muslin, sufficiently close in texture to prevent dust getting to the turpentine, and yet not so close as to prevent evaporation. A very good plan is to place the saucer, mouth down, on the muslin, and cut the latter with a ¾-inch margin, then make a narrow hem in the muslin, into which may be run a piece of round elastic, this should then be drawn sufficiently tight to catch well over the edge of the saucer. The arrangement is shown in Fig. 21. The saucer with its turpentine should then be put in a place where evaporation will be free. It should not, however, be put over the fire or a stove so as to hasten the evaporation, or the heat might dissipate the whole. When the spirituous part of the liquid has passed off there will be found left the oil at the bottom of the saucer. Fresh spirit may be added, and the process repeated until there is enough oil to pour off.

(*b.*) *Tar.*—The spirit of tar is in two shades—one a rich amber, the other a dark brown, but both are alike in nature. The oil of tar corresponds to it in the same way as the oil of turpentine does to

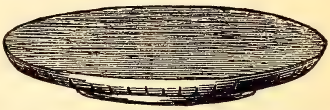

FIG. 2ˉ.—SAUCER FOR PREPARING OIL OF TURPENTINE.

the spirit of turpentine. The spirit and oil of tar are of similar use to the other spirit and oil, and are employed principally by those who object to the vapor of the turpentine as causing headache or affecting the throat.

The spirits of turpentine and of tar are extremely volatile, the former being somewhat more so than the latter; and during the working, sufficient may pass off to render the paint somewhat difficult to deal with. This difficulty is, however, only a slight one, and is easily overcome by the use of a little

(*c.*) *Oil of Lavender*, or oil of spike, as it is sometimes called. This is a perfectly volatile and fluid oil, but very much less volatile than either of the above-mentioned spirits, and a small quantity is added to the other mediums used when it is desired to keep the work *open*, that is—to counteract its drying or fattening through loss of spirit.

Caution.—Fat oil is not entirely free from one of the objections raised above, to the use of the mediums regarded as unsatisfactory, inasmuch as it too will boil up, or blister, or blib, or spit, if used in excess; but in this case the remedy is easy: 1, not to use too much; 2, if much must be used, it can, while fresh, be easily evaporated to dryness with the exhibition of moderate heat.

Boiling Up.—It may here be explained

that the result of boiling up, when there has been too much oil mixed with the paint, is that rough, jagged, or broken-blistery appearance, which is similar to that presented when a glaze has been subjected to a greater heat than it was made to bear, and which may often be seen on common goods. The boiling oil bubbles and raises a thin film of paint. The paint subsides to the edge of the bubble, and when the latter bursts there is left a rough-edged hole, with but little if any paint within its edge, but with too much round it.

33. *The Mediums should be kept* in bottles with closely-fitting stoppers, especially the spirits, as otherwise these would quickly become "fat" by evaporation. For general purposes, corks are preferable to glass stoppers. The plan I have found best is, on getting a new bottle of turpentine, immediately to decant the whole into small bottles. When a large bottle is only half full, the oxygen of the air in it attacks the turpentine with the formation of water and resin. The most useful are little drop bottles, like those in which homœopathic medicines are usually put up, and which are furnished with a little spout.

PAINTS.

34. *General Composition.*—The colors used in painting upon china or earthenware are, for the most part, oxides of certain metals. In only a few cases are the metals in a simple state used, those principally so employed being gold, silver, platinum, and copper; and these are so used only when the natural sheen of the metals is required, or in bronzes. The metal oxides having been rendered as nearly chemically pure as possible, are either singly or two or more in combination, and in the form of a powder, intimately mixed with triturated colorless glasses of varying composition, according to the nature of the oxide and the degree of hardness required in the pigment. The mixture, as ready for use, is an impalpable powder.* When this mixture of colored oxide and colorless glass is, with the aid of the mediums which have been described, properly applied to the glazed ware, and the painted ware gradually raised to a certain degree of heat in a specially constructed kiln called a muffle, the glaze of the ware, which we have seen to be a modification of glass, and the glass forming part of the mixture, both soften sufficiently to enable them to coalesce, and in this increased thickness of glaze, the coloring matter is, in the large majority of cases suspended, and in particles so fine as to be separately discernible only in thin films under the microscope. A few colors, however, such as the deep transparent blues, and yellows from one source, are really, to a certain extent, stained glasses, the glass having more or less completely dissolved the coloring matter. China or enamel colors then, from their containing, as an essential constituent, a glass or flux of vitrifiable composition, are called *vitrifiable pigments.*

*On the more particular composition of china colors, as affecting their tints in combination, I shall have to speak in a future paper, when treating of colors arising from mixture.

35. *Home Manufacture of Colors.*—In this connection I may notice a question which has not unfrequently been put to me, viz., whether an amateur cannot make his own pigments. The answer is that in general it is quite possible for him to do so, but whether it would be a profitable undertaking is quite another matter. The conditions essential to the production in all their perfection of some of the most beautiful colors are such as are not attainable except with a very large expenditure of money, and in circumstances which do not exist in private houses or even in ordinary workshops. In such cases the requisite expenditure could only be profitable with production on an extensive scale and where part of the necessary "machinery" is utilizable for other purposes besides mere color-making; and the circumstances, which include, among other things, the obtainment, perception, and maintenance to a nicety of different degrees of heat in furnaces of special adaptation are not to be found united except in factories devoted to the business.

(*b*) *Flux.*—But these are not the only considerations. A very great difficulty in

the way of attaining perfect success in color-making is the adjustment of the flux. Indeed, it is scarcely too much to say that this constitutes the nicest and most delicate part of the whole process. 1. The flux should be suited to the pigment as regards the composition of the latter; 2, it should be proportionate in quantity to the pigment according to its nature; (3) it should uniformly cohere with the glaze of the ware beneath; and, 4, the different fluxes, whatever their composition, should always vitrefy at one uniform temperature. The degree of nicety to which this adaptation must be carried will be appreciated when it is stated that an excess in one of the ingredients only amounting to between ·3 and ·4 per cent. of the flux may destroy the color.

Speaking generally, then, it is not to the amateur's interest to endeavor to be his own color-maker. To expend dollars on a furnace when for as many dimes he may get as much color as will in the ordinary way last him for some years, will not *pay*. Of course there are a few colors which may be made at home, but even as to these I am inclined to doubt that the domestic manufacture of them would be profitable except as a pastime, seeing that those most easily made are among the cheapest. There are published recipes on the subject which may be consulted by the amateur desirous of trying his hand in this line; but apart from the consideration that some are scarcely intelligible in modern strictness, and others are known to be incorrect, I think I have said enough to show that, except in a few cases, *le jeu ne vaut pas la chandelle.*

36. *Employment of Different Makes in one Painting Unadvisable.*—The point (4) noticed in the last paragraph but one demands further attention as bearing greatly on a very practical consideration. It is essential to the "finish" of a picture that after the firing all the colors should be equally glossy, and should have equally and completely adhered to the glaze of the ware. This end, so far as the painter is concerned, is, as a rule, to be attained by the use in any one painting of the colors of *only one* maker. It is the fact that there is one recognized standard of heat for firing enamel colors, and at this heat, technically known as "rose-color" heat, the color should be developed in all its perfection; but, unfortunately, it is not always the case that colors of *different* makers will fire properly at one heat. In these circumstances it is with pleasure and confidence that I recommend for general use the colors which I now employ, after an experience of those of three other makers, viz., those of the manufacture of Messrs. Hancock & Sons, of Worcester, Eng. Of these I cannot speak too highly. The grinding of them is complete, they do not concrete, they all vitrefy and develop equally, and, a not unimportant point as regards price, the quantity in the No. 2 sized bottles compares very favorably with that offered by other makers.

37. *Dry* v. *Moist Colors.*—These are now issued in the forms of dry powder, oil medium paste, and moist water-color. The relative worth of dry and oil-paste color has been much debated, but it is sufficient to say, that while it must be conceded that there is on first opening a fresh tube of color mixed with an oil medium, some advantage in respect of convenience, it is undeniable that in every other respect the advantage is on the side of the powder color. I cannot do better than give some of the "reasons" of the firm for originally deciding upon powder color:—

"I. Professionals know from experience that the sooner colors are used and fired after mixing with oils, etc., the brighter and better they will be when fired.

"II. Dry colors may be mixed thick or thin as they are required; whereas, if tubes are used and the color is too thin, it is difficult to make it stiffer for any particular purpose," without at the same time running the risk of having the mixture too fat. [A. de V.)

"III. Colors kept in tubes are apt to separate from their oils, if kept any length of time, thereby necessitating the trouble of re-mixing with a palette-knife (as much trouble as mixing in the first instance).

"IV. There is considerable uncertainty in producing, by mixture of various tube

colors, a given tint, for grounds, etc., particularly for large work, as they vary in consistence, and are therefore difficult to measure; whereas, the proportions of dry colors may be correctly weighed, and if a memorandum is kept, the exact tint may be reproduced with certainty, without further experiments.

"V. Moist colors in tubes are apt to become in time, what is technically termed 'fat,' which makes them liable to blister in the fire. Dry colors may be mixed with as little fat oil as experience proves necessary for the particular kind of work in hand, and the artist has it in his power to render them 'fat' or 'cutting, according to the requirements of his work, at the moment."

It is claimed too that the purchaser of dry color has this further advantage: that he obtains so much of the dearer pigment in place of the cheaper medium; and certainly, taking quantity for quantity, a comparison of the prices of the No. 2 sized bottles with those charged by other makers for moist colors, fully supports this claim, and this should be a leading consideration with the amateur, who may save not only the maker's cost of mixing, which is a very simple operation, but also his interest on such cost.

I may add to the foregoing "reasons," that in a foreign moist make which I have used, I have found tubes from which it has been impossible to express the paint, which had become as hard as a rock.

(To be continued.)

Christmas Greens Botany.

BY A. W. ROBERTS.

TO one who has his eyes wide open, much that is instructive and interesting in botany may be learned at any of our large markets during the two weeks preceding Christmas; for next to the big and little Christmas trees, comes the loose Christmas-greens, roping, etc., etc., that are used. In this branch of Christmas greens much interesting information is to be gained, as, for instance, the fact that large shipments of the English mistletoe are received through the Custom House some two weeks before Christmas. This English mistletoe is eagerly bought up by our English, Scotch, Welsh, and German adopted citizens. In habit the mistletoe is a true parasite, and feeds on the sap of the tree on which it grows. The fruit of this curious evergreen consists of a semi-transparent berry, the flesh of which is very sticky, and contains a single seed. The favorite trees of the mistletoe are the apple and oak. So much is this the case with apple trees in some parts of England, where they are cultivated extensively, the mistletoe has become the great pest and destroyer of the apple orchards. But the most curious fact regarding the planting of the seed of the mistletoe is, that it is entirely due to the birds of England that remain in that country during the long winter months; these birds being hard pressed for food, are forced to feed on the sticky berries of the mistletoe, the seeds of which they leave sticking to the branches of the tree on which the mistletoe is growing. These seeds, in course of time, germinate and live on the sap of the tree. As the English mistletoe does not grow in the North of England or Scotland, florists are in the habit of planting the seeds of the mistletoe on young apple and oak trees, and, when the mistletoe has attained a good size, the trees are disposed of at high prices, they being a great curiosity in Scotland and the northern parts of England. The mistletoe was greatly venerated by the ancient Britons, and was considered by the Druids as an absolute and sacred charm against disease and misfortune, the priests at certain seasons of the year, with great solemnity, gathered it from the oak trees with a golden sickle. The ancient custom of kissing under the mistletoe bough during Christmas times, has been handed down since the feudal times. The leaf of the English mistletoe is long and graceful in shape, whilst that of our native mistletoe is short, rounding and clumsy looking; of this variety large quantities are gathered from the live oaks of Florida to be disposed of in the northern markets during Christmas time. From the berries of the mistletoe, the very best of

bird-lime is made by the young naturalists of England, who, being desirous of obtaining the birds of their country in

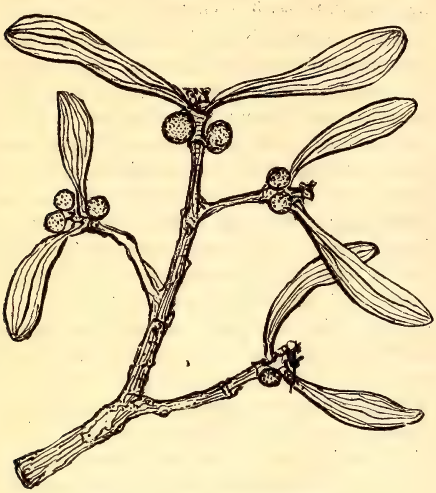

Fig. 1.—ENGLISH MISTLETOE.

their most perfect plumage, make use of the bird-lime in preference to shooting them, which often destroys valuable specimens.

Fig. 2.—AMERICAN MISTLETOE.

One of our most common of Christmas greens, and which is used mostly for the making up of "roping," is the "ground-pine." This beautiful evergreen belongs to the family of club mosses or Lycopodiums of the botanists, and by the florists called "bouquet greens," as large quantities of it is used by them during the winter months for making up bouquets when other green material is scarce. When the flowers of the ground-pine are ripe, they are collected and dried, after which they are shaken and sifted to obtain a powder of a sulphur-yellow color which is the spores of the plant. This curious powder is sold by all druggists, by the name of *Lycopodium.* When in a mass, it is very mobile and smooth to the touch. Druggists use this powder when making pills to prevent them from sticking together; and also in cases where a person's skin has been badly rubbed off through some accident, this curious powder is dusted over the wounded part to which it adheres, and forms an artificial skin. There are other curious qualities possessed by this powder, as for instance, if the surface of a bowl of water is dusted over with it, and also some of it be rubbed over the hand, a piece of money or other object when placed in the water, can be removed from the bottom of the bowl without wetting the skin, the powder seeming to possess a negative or repellant quality to that of water somewhat like oil or other greasy substances. Another interesting quality possessed by this powder, can be illustrated by placing a small quantity of it in a quill or paper tube, or what is still better, in a syringe. Then if the powder be discharged against a candle or gas light, it will produce an instantaneous flash like that of lightning.

The ground-pine sells readily to florists at three dollars a barrel, who generally make up their own Christmas roping. Common roping can be purchased as low as two cents a yard, but it is very thin and apt to fray out in a short time. The best roping sells for five cents per yard. Thousands and thousands of yards of this material are used every Christmas for home, church, and Sunday-school decoration. The larger part of it comes from New Jersey, packed in barrels, which, when kept in a cool and damp

place, will retain its beautiful green color for several weeks. A few weeks before Christmas, hundreds of poor boys and girls are hard at work gathering and winding the ground-pine into roping, and by this means earn enough money with which to purchase warm winter clothing or pay off the taxes on some

Fig, 3.—GROUND-PINE.

small fruit farm. So my merry young readers, when you are festooning your homes or Sunday-school room with this beautiful Jersey evergreen, think how very many little girls and boys have been made happy by gathering and making it up for the boys and girls of New York City.

From Florida large quantities of Spanish moss are sent north a few days previous to Thanksgiving and Christmas. This beautiful moss answers a double purpose. First as a soft and dry material in which to pack the luscious Florida oranges, and also that of a beautiful and graceful evergreen for Christmas times, the cool greyish-green color of which contrasts well with the rich dark greens of our northern evergreen. This curious Spanish moss, as it is called (though it is not a true moss at all, but belongs to the pine-apple family or the *Tillandsias*), has also a considerable commercial value, it being used very extensively by upholsterers for stuffing mattresses, sofas, etc. The process of preparing the moss so as to rid the inner, woody, horsehair-like fibre of its soft outer coating or "bark," is a very slow and tedious one. After gathering it from the trees of the live-oak on which it grows (for like the mistletoe, it is a parasite, though it does not live on the sap of the tree as do the mistletoes, but obtains its support from the moisture of its surroundings and the atmosphere), it is buried in the ground, or is placed in running water, where it is allowed to remain until the outer covering or "bark" is more or less rotted; it is then dried and beaten, and baled, after which it is sent north to be ginned. The

Fig. 4.—FLORIDA MOSS.

ginning removes all small particles of "bark" that still remain attached to the fibre, and at the same time, clears it of dust and foreign substances. It now looks very much like coarse and black horse-hair, and when in a mass, has great spring to it, almost equal to curled horse-hair, and is worth fifteen cents a pound. You would never recognize this material as the once beautiful Spanish moss of Florida.

The holly with its beautifully shaped leaves, and clusters of bright crimson berries, is, undoubtedly, one of our most attractive evergreens, but the leaves soon lose their vivid green when placed in a dry and hot room, otherwise it would outrank all our native evergreen trees. Last year several cases of English holly were sent to New York dealers as an experiment, but it proved to be a failure, in consequence of the leaves falling off after their long journey across the Atlantic ocean.

The best bird-lime for catching birds, mice, and other small animals, is made from the middle bark of the holly, which is well bruised and boiled in water for four or five hours. The water is then poured off, and the bark is placed in pits dug in the earth, and covered with stones. At the end of a fortnight or three weeks, it will have changed into a sort of mucilage by the action of fermentation; it is then pounded in a mortar until reduced to a paste, washed and kneaded in soft water to rid it of all earthy or vegetable matter; it is again placed in the earthen jar for four or five days to purify itself by fermentation, after which it is put up for use. Thousands of young holly trees are manufactured every year into walking canes; they are stained a deep black in imitation of ebony, and the wood being close and heavy, very few people know the difference when highly polished.

Fig. 5.—THE HARTFORD CLIMBING FERN.

The "climbling fern" or "Hartford fern," is one of the most beautiful of all our native ferns. The striking delicacy, beauty of foliage, and graceful habit of this fern adapt it to decorative purposes in its green state; or when carefully pressed and dried, it is formed into graceful festoons and attached to white curtains, or draped around pictures. Thousands of sprays of this fern are gathered and pressed every year to be disposed of by florists during Christmas times. So great became the demand for it, that there was danger of its becoming extinct in the locality at East Windsor Hill, Connecticut, where it grew in great abundance. So large were the quantities taken away yearly, that an act was passed by the Legislature forbidding its wanton destruction. There are two methods of drying and pressing this fern; one is known as the "dry pressed," and the other as the "hot pressed"; the "dry pressed" consists in placing the ferns between sheets of paper or dryers, which are changed every few days. The "hot pressed" is where all moisture is evaporated from the ferns by means of hot flat irons, which are rapidly passed over the ferns; the dry pressed ferns always retain their colors best.

A Skate Foot-Scraper.

SINCE the advent of the beautiful strapless skate, thousands of the old-fashioned "turn-ups" and English skates with their numerous straps and buckles, have been cast aside. In my travels I have come across them hung up in woodsheds, cellars and barns, rusty and uninviting

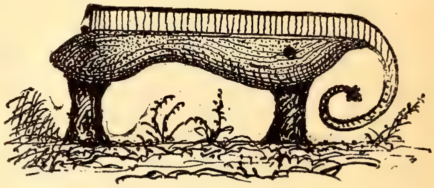

Fig. 1.

looking. No one cared to destroy them, as they had been in the family so many years, and yet there seemed to be no useful way of disposing of them. Having just such a rusty and mouldy pair of "turn-up" skates in my possession since

early boyhood days, I determined to turn them to some account, and yet preserve them as souvenirs of happy boyhood days. After taking away from the body of the skate all the heel and toe-bands, and straps, I burned four holes wit' a heated wire poker through the wooden foot piece of the skate; through these holes were introduced four long screws, which were screwed into the two hickory or chestnut stakes, or uprights shown in the illustration, Fig. 1, these stakes having been first firmly driven into the ground. After the skate was firmly screwed in position on the two upright stakes, both it and the stakes received two coats of green paint, and the result was an excellent scraper for taking mud off boots and shoes.

Fig. 2 shows how an old gate or barn-door hinge may be utilized for the same purpose. This shows one wing of a strap hinge run through two upright pieces of wood. The mode of construction and means of fastening, are quite obvious.

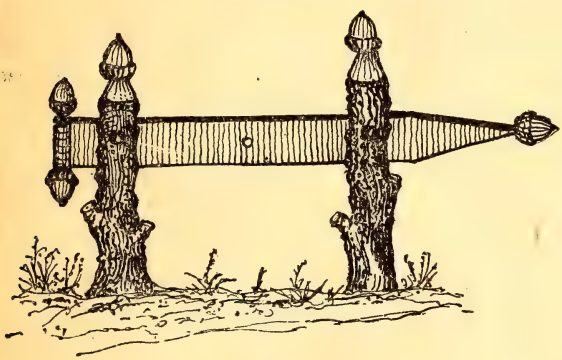

Fig. 2.

Canaries: How to Keep and Breed Them.—V.

BY GORDON STABLES.

CANARIES can be taught a variety of little tricks after they have come to love you. They may also be taught the notes of various other birds, or they will learn tunes played to them on a bird-organ or flute or violin. In either case they must be taught while young, and they must be so placed that they can hear no sounds save those you wish to teach them.

Cats, I may just remark, should be taught to respect your birds. Pussy often gets extremely attached to canaries, and will protect them, but never think of hurting them. I have seen a canary placed in a cat's pen at a show to keep pussy company and sing to her.

Let me conclude by mentioning a few of the ailments canaries are liable to, though these can mostly be prevented by avoiding their common causes, namely, 1, damp; 2, draughts; 3, want of ventilation; 4, the abuse of dainties; 5, bad food; and 6, impure water.

Asthma.—A little glycerine in the water, with a rusty nail, and fifteen drops of tincture of gentian.

Diarrhœa.—Two drops of warm castor-oil first. After a few hours, a small bit of gum arabic, and about twenty drops of tincture of opium in the water, or a little of the ordinary chalk mixture of the shops.

Constipation.—This is a complaint which is more easily and successfully treated by change of diet than by medicine. Give more green food in summer, and in winter a slice of ripe apple or well boiled carrot. If the case is urgent, give two or three drops ofcastor-oil.

Inflammation of the bowels.—The bird is dull and drooping, perhaps lying on its belly on the perch, and evidently in great pain. The lower part of the stomach will be found red and swollen. Give a drop or two of castor-oil to begin. Paint the abdomen, by means of a camel-hair brush, with warm turpentine. Put in the drinking water twenty drops of wine of ipecacuanha, and a bit of gum arabic; or put a drop of each of the former medicines, diluted in two or three drops of water, down the throat thrice a day. Keep warm and handle gently. When the bird begins to come round, feed on steeped biscuits of arrowroot and sweet milk.

Fits.—Fright often brings these on, and the bird may die in one. Hold the sufferer in the open air; blow on it and sprinkle it with water, but do not do this for about a minute after it falls down. The heart cannot recover suddenly. Hanging the bird in the sun or too near the fire may induce apoplectic fits. They are highly dangerous. Take the bird to the cool fresh air, and endeavor to get it to inhale the aroma from a smelling-salts bottle. It will come round gradually. Be careful with your feeding afterwards.

Cramp.—Open the bowels with castor-oil, then put a few drops of paregoric in the daily drinking water. Change the diet; it must not be too stimulating.

Pip.—A name given to a small pimple on the rump. Open with a fine needle when matter is apparent, then dress with cold cream.

Sore feet.—Clean and wash, and anoint with cold cream. Turn the bird into a clean dry cage, then thoroughly do out the old one.

In all cases of illness examine the bird, holding it gently but firmly the while all over. A change of diet is always necessary in sickness, and more warmth. Put the patient in a comfortable well-ventilated room, and see that it wants for nothing needful.

Answers to Guesses.

THE following answers have been handed us in reply to the calls for "guesses" made last month. The answers are correct in each case.

We should be pleased to have the readers of the YOUNG SCIENTIST take a part in this column, as we are sure they may make it both interesting and instructive.

Answer to No. 1.—Meal-worms, sold by all dealers in birds. Used as a special

MEAL-WORM.

food for all the soft-billed birds, mocking-birds, thrushes, sky-larks, etc., etc.

Answer to No. 2.—Tree-toads, kept in glass jars as pets. When a storm is coming, they climb to the top of the ladder, and begin to trill. All Germans are very partial to them. The green variety, common to all Germany, is known as the barometer-frog, and is kept as a pet.

Answer to No. 3.—Our common yellow bird. By depriving any wild bird of its flight feathers, and allowing it the freedom of a room, in course of time it ceases all attempts to fly away; but, when its flight feathers grow out again, off it goes.

Answer to No. 4.—Gathering angle worms. The first man sold them for rum to liquor dealers, who had pet robins or mocking-birds. The second man who gathered them for his pet, had a pet thrush. The fourth man, to use as fish bait on one of the East-River docks, where the lafayette fish were very abundant at the time. He was out of work and out of money, but took this means to provide a breakfast for his family.

Plan for the Furnishing and Decorating a Young Lady's Apartment.

WE will suppose the apartment of a young girl from thirteen to eighteen years of age, decorated with mural hangings in the form of panels of white muslin plaited over a painted design, and enframed in a puffed border of some light material, such as silk, and tufted with small buttons embroidered with braid. This style of decoration is quiet to the eye; the lines are light, simple, and elegant, and the effect produced by the painted design being seen through the folds of the clear muslin, gives an effect suitably fresh and childlike. Bows of ribbon and such like ornaments should have no place here, appertaining, as they undoubtedly do, to a later stage of feminine coquetry, and, though every article in the apartment should display the most *recherche* taste, quietness and simplicity should be the most striking characteristics.

The ceiling is to be hung in the same style as the walls, and composed of an oval and four corners, surrounded by a tufted bordering or frame like the walls. A separate flap of muslin over a painting replaces the cornice in this style of decoration, and at the bottom of this flap is a narrow band of gathered muslin falling over the top of the hanging. The chimney-glass, to be in keeping with the rest, is surmounted by a drapery of clear muslin, the folds of which, draped on either side, replace the tufted frame of the other sections. The dainty bedstead has flowing white double curtains, the interior ones covered with a light embroidery, and the outer ones edged with a narrow drapery forming insertion work.

A plaiting of white muslin, radiating

from a centre, in the shape of a sun, extends over a painted design, and forms the ceiling of the bed.

The coverlit is also composed of embroidered muslin to match the inner curtains. The drapery of the windows and *portieres* must correspond in material and design with that of the bed, with a heading of ruching and small gobelets above each fold, and gathered in the space between each gobelet.

The rest of the suite of this apartment is a cheval-glass or mirror wardrobe, a small secretaire or writing-desk, a night-table, a prie-Dieu, a small sofa, a *chauffeuse* or lounging-chair, and four other chairs of a light and elegant form, simple in effect, not to be out of keeping with the general result.

The execution of the decoration we have just described, though very simple, requires nevertheless great attention and care, especially in the taking of the measures. A plan rigorously adopted on the scale of proportion facilitates the work to be done to a very great degree; for it is only by means of this precaution that the excellent French maxim, "Before driving in the first nail it is well to know where you will drive in the last one," can receive its practical development.

With regard to the frame of the panels of this style of hanging, it is usually of strong card-board, or, better still, of wooden laths about a little more than half an inch in thickness each, and thinned off at the extremities. When this frame has been well adjusted to the exact measure required, a piece of strong linen should be glued over each joining, which gives a great deal of solidity to the whole. The frames of the ceiling and of the separate flaps should be formed of lath somewhat thicker than those that compose the frames of the panels. When all has been well adjusted according to the required measure, the tufting is traced and the frame bored with a gimlet at the place marked for each section of the tufting. This done, a layer of good horse-hair of about $1\frac{1}{2}$ inch in thickness, and over this one or two layers of wadding over the whole extent of the frame. Then the material used for covering the frame is prepared, that is to say, the corresponding number of sections with those on the frame, traced on the reverse side, with sufficient amplitude allowed to each section of the tuftings, and the material pierced with a bodkin at each section to mark the corresponding hole in the wood-work of the frame. Thus prepared, the material is placed over the wadding without being nailed down. Then the braid is placed on the material, and tightened as much as possible, and in such a way that the braid be exactly on the trait made on the frame. Then tuft with a fine needle, passing it through the holes in the woodwork and the material, the thread *passing over* the braid, and rather tightened. When no buttons are used, braid replaces them in this style of tufting, and gives considerable lightness in the general effect.

This tufting being executed, the material is turned down and nailed just on the edge of the frame if a gimp be used as binding, or below the edge if a cord.

With regard to the panels, after the execution of the frames which we have previously described, the painted designs having been carefully and smoothly hung in the places marked out for them, the muslin, or, better still, the grenadine panels (grenadine being at one and the same time much more transparent and durable than muslin) are simply gathered top and bottom, with an allowance in fulness of one-third to the whole—in other words, one-half over and above. Thus prepared, the muslin is now tightly stretched over the painted design, and in such a manner that the gathers are very straight and parallel with each other and as numerous as possible. The frame is placed and fixed to this, and a cable or light twisting of the material, silk or other, employed in the hanging surrounds the whole, producing an effect which is almost sure to be admired for its dainty elegance, novelty, and simplicity.

It will be understood that the painting to which we have referred should be both designed and executed with proper reference to its effect when treated in the way described.

The framework of the ceiling is prepared in the same manner, with due reference to the point from which it will be examined when completed.

We have a very important observation to make here with regard to the cutting destined to cover the separate flaps. All the gathers of this piece of muslin converging to one point, consequently become larger and larger as they approach the angles. To trace the cut of this muslin, a tracing of the real dimensions of the flap should be first executed; divide the line of top and bottom into a given number of equal parts with not too much space between: join the corresponding points at top and bottom by lines. These lines will, of course, become larger and larger, parting from the centre, and will be a certain and sure guide for the development of the muslin by proceeding as follows:—

Draw a straight line equal in length to one length and a half of the length of the top of the flap; divide this line into as many equal parts as you have divided the first tracing. From each point of division of this line (which represents

the straight thread of the muslin which is to be gathered at the top of the flap) drawn down perpendiculars, the length of which will be given by the corresponding lines drawn from top to bottom of the first tracing, the extremities of these perpendiculars deciding the direction of the cutting-out, which forms a curve. If each part of the top and bottom be gathered carefully and with regularity, the result cannot fail to be satisfactory.

We have been induced to present this type of decoration to our readers, in the hope that they may derive advantage from the directions and suggestions we have given, which will be found applicable on many and divers occasions besides the present one. In Paris upholstery decoration for such apartments has been extensively adopted, and we have seen similar effects carried out in both Germany and America, with certain modifications and variations, to which we may return on another occasion.

Our Girl's Department.

This department is intended exclusively for "Our Girls," and we hope to make it both interesting and instructive, and to this end we ask our young lady readers to assist by contributions, suggestions, or illustrations. There are thousands of little things that can be, and have been, made and done by young ladies, pertaining to decorative art, needlework, etc., etc., that would be gladly followed but for a want of knowledge on the subject, and we know of no more pleasing task for a lady than that of teaching her younger sisters that which they are anxious to learn, and which may prove of real benefit to them in the future, as well as being useful and interesting for the present. We trust we will have no difficulty in persuading those who have something nice to show or speak of, to make use of this department. Remember, it is open to all, and if you have anything worth knowing suitable for this column, send it along, and we will give it our best attention. Do not be afraid to write because you may fancy your composition is not perfect, or have other scruples of a similar kind. Do the best you can, and leave the rest to the editor of this department, and we are sure you will be pleased with your work.

Brown-eyed Ruth, the Quaker's daughter,
In her dress of simple grey,
Walked beside her quiet grandpa
'Mid the garden flowers of May.

Bed of tulips bright and golden,
Hyacinths of every shade,
Pansies, like sweet childish faces
Looking up to greet the maid.

How they revelled in the sunshine,
While 'mid clumps of violets blue,
Filling all the air with fragrance,
Glistened still the morning dew.

Then outspoke the little maiden,
Looking at her dress of grey,
"Grandpa, can thee tell t e reason,
Why God made the flowers so gay,

"While we wear the quiet colors
That thee knows we never meet,
E'en in clover or the daisies
That we trample under feet?

"Seems to me a Quaker garden
Should not grow such colors bright."
Roguishly the brown eyes twinkled
While her grandpa laughed outright.

"True it is, my little daughter,
Flowers wear not the Quaker grey;
But they neither toil nor labor
For their beautiful array.

"Feeling neither pride nor envy,
'Mong their sister flowers, thee knows,
Well content to be a daisy
Or a tall and queenly rose.

"Keeping still the same old fashions
Of their grandmothers of yore;
Else how should we know the flowers,
If each spring new tints they bore?

"Even so the Quaker maiden
Should be all content to day.
As a tulip or a pansy,
In her dress of simple grey."

Once again the brown eyes twinkled;
"Grandpa, thee is always right;
So thee sees, by thy own showing,
Some may dress in colors bright.

"Those whom thee calls worldly people,
In their purple and their gold,
Are no gayer than these pansies
Or their grandmothers of old.

"Yet thee knows I am contented
With this quiet life of ours,
Still, for all, I'm glad, dear grandpa,
That there are no Quaker flowers."

— Twenty-five years ago there was sold in Milan a library of 30,000 volumes, all of which were of woman's authorship.

— In Nebraska there is one woman who is an ordained preacher of the Gospel, ten who are physicians, one lawyer, and six who are county superintendents.

— The Queen of Denmark, mother of the Princess of Wales, is an accomplished painter, and has lately presented the little villiage of Klitmoiler, in Jutland, with an altar-piece, entirely executed by her own hands.

— A portrait of Ignatius Loyola, in needlework, the work of French nuns, has been shown at an exhibition. It is only about six inches long, and was worked entirely in knots so fine that the stitches could not be seen without a magnifying glass.

— Mrs. Susan P. Moulton, of Salem, has received a patent for a railroad shackle which is very simple in construction, effective in operation, and if put in general use it is believed would cause a great diminution in the number of accidents in making up a train.

— Miss Mary E. Lovejoy, of Bangor, Maine, is quite largely engaged in the silk business. She has at present 3,000 silk worms. In thirty days from hatching the worms begin to spin, and in nine days more the cocoon is ready to be reeled and spun. It is thought that the silk raising business can be made profitable in Maine.

— Mrs. E. A. Burke, wife of Major E. A. Burke, editor of the New Orleans *Times-Democrat*, has accepted the superintendency of Lafayette-square, the most beautiful spot in that city, whereupon the New Orleans papers are rejoicing, as Mrs. Burke is a public-spirited lady, and will discharge the duties of the position faithfully.

— The town of East Turner, says the Lewiston (Me.) *Journal*, is bragging about a smart girl. The young lady's name is Eva French. She is 16 years of age. In consequence of scarcity of help in the haying season, Miss French, whose father is one of East Turner's well-to-do-farmers, put on her broad-brimmed hat and went into the hay-field. She has this summer driven a pair of horses on the mowing-machine to cut twenty-five acres of grass, and has raked the same with a horse-rake and pitched it into the barn with a horse pitchfork. The farm cut nearly forty tons of hay. In addition, Miss French can bake as good a batch of biscuits or do housework as well as any housewife in Turner.

BEFORE QUESTIONING THE POP.

Sighed the slim to the belle, "Aw, miss, can you tell
Why I'm like that apple you plucked from the tree?"
"Because it," she coughed, "is remarkably soft?"
"Aw, no; it needs paring by you," stammered he.

"Re-pairing, you mean, though because it is green,
And rather insipid, might answer," laughed she,
"And not fully grown." Said the dude, with a groan:
"Aw, were I that apple, perhaps you'd halve me."

"And quarter you, too. Oh, for 'sauce' you will do,"
Spake the miss; "but, now tell me, why you're like the tree?"
"Because—I've a heart," blushed the slim, growing smart.
"Because—trees are sappy and crooked," said she.

"Aw, you're," smiled the slim, "like the tree for you're woo'd."
"You'd better say 'bored,'" said the miss, "as I'm now;
But trees, you perceive, make a bough when they leave,
So you, to be like them, may leave with a bow."

— "Who grasps the moment as it flies, he is the real man." There is a good deal of food for thought in this short sentence for every wife and mother who reads this column. To grasp the right moment in our lives is of so much worth to us; to enjoy the prattle of our children even in the midst of daily anxieties and all the hurry of a busy life; to take the time to smile an answer with the kindest words the friends who sometimes interrupt our work, and, as we are apt to say, waste our day. How much better to do this now rather than to cry out in later years for the impossible; to say, "Oh, for one hour with my little children!" when they have become men and women, and are beyond our reach, and we are left remembering the many hours in which we were not patient with their little hindering ways, and in which we did not grasp the possibilities of happiness. Then, in very homely ways, to grasp the flying moment is profitable; to care for all the material interests of the house-

hold when they should be cared for; to put up the ripe fruit before it has time to soften; to mend the little holes in stockings, the rips in gloves. If women who have work to do would not waste time in useless fretting about the unchangeable nature of their work, they would gain in time and strength.

— Engagement rings are the natural sequences of the summer campaign of the belles of the watering-places, and many a young man is at his wits' end to raise the necessary cash wherewith to secure the preliminary token of future domestic bliss. Ice cream, drives, boating, and pleasure excursions generally have depleted the pockets of the devoted beaux, and in many instances when the question, the momentous question, was asked, it was with fear and trembling that the expected answer was received. On leaving, the happy girl generally says:—"When you get me my ring get me a nice one, Charley, for I want to be proud of it, and all the girls will criticise it, you know. Get a nice solitaire with a skeleton setting, so the diamond will show nicely. I think a pure white stone is the best. That hateful Laura has a colored one, and I believe it is full of flaws. She is always showing it, anyhow, and if she hasn't a scratch on her finger she is continually fixing her hair or arranging her collar. I want a better stone than hers. Won't you get it, dear?"

"I will, darling; I'll get you the best in the market," and he departs with a sinking heart.

The next day he makes an arrangement with some jeweller by which he gets an inferior stone at a high price, which he pays for in weekly instalments. Visits to his girl and the usual presents and theatricals take the remainder of his salary, and when the wedding-day approaches his or her fond parent is obliged to hand over the necessary funds to unite the twain and send them off on their bridal tour. On their return they generally settle down, and the question of the engagement-ring and the attendant incidents form a subject of jocular conversation between them.

— Fifty females employed in the Mint at San Francisco are called adjusters, and their pay is $2 75 a day, counting week days and all holidays but Sundays. Their hours are from 8 o'clock in the morning until 4 in the afternoon, with the exception of Saturdays, when they cease at 2 o'clock. These adjusters occupy two large rooms on the second floor of the Mint. One is used for the adjusting of silver and the other for that of gold. The floors are carpeted, and each lady has a marble-top table, a pair of scales, and a fine, delicate file. Before the gold is turned over to them to be adjusted it goes through the process of being rolled, annealed, cut, and washed. They then take it in a state called "blanks," that is, perfectly smooth, and the weighing is done. It is weighed to see if each piece be of standard weight, which must be of 412½ grains for a silver dollar, a slight discrepancy being allowed on either side. If a coin is found outside of the limit after being weighed by an adjuster, it is returned; if too light it is condemned, and must be remelted; if too heavy, it is filed to its proper weight. This is the ladies' work, and an interesting sight it is to watch the small white fingers deftly handling the shining pieces. A room near the adjusting room has been set aside for the ladies, who use it as a lunch room; two long tables are provided, and a janitress furnishes boiling water for making tea, and also keeps the place neat and clean. Several of the ladies have been in the Mint for several years

---

DICTIONARY OF OSCULATION.

Buss, a kiss.

Rebus, to kiss again.

Pluribus, to kiss irrespective of sex.

Syllabus, to kiss the hand instead of the lip.

Blunderbus, to kiss the wrong person.

Omnibus, to kiss all promiscuously.

Erebus, to kiss in the dark.

Incubus, to have to kiss some one you don't like.

Harquebus, to kiss with a loud smack.

THE

Young Scientist.

A Practical Journal for Amateurs.

(With which are incorporated "THE TECHNOLOGIST," "THE INDUSTRIAL MONTHLY," and "HOME ARTS.")

PUBLISHED MONTHLY AT $1.00 *PER YEAR.*

EDITORS.

SEE WHAT WE ARE GIVING AWAY TO EVERY SUBSCRIBER.

THE success which has attended our efforts during the past year, since the enlargement of the YOUNG SCIENTIST, has determined us to make it still better during 1884. We are now completing our arrangements for accomplishing this—making contracts with contributors, engravers, paper makers, printers, and others—and we are anxious to get our subscription list into shape as soon as possible. We have therefore determined to make the following tempting offer: To every one that sends to this office a subscription for 1884 at full rates, before the 1st of January next, we will send a copy of the "Workshop Companion." This is a book of 164 closely-printed pages, full of matter that is just what every one of our readers, boys and girls, wants. The price is 35 cents, strongly and neatly bound, so that those who accept our offer get the YOUNG SCIENTIST for almost half price.

If you want a copy of this work on these terms, send at once before you forget it.

Subscribers will oblige us very much by sending in their remittances before the first of the year, as by doing so, we may keep their names on our books without change, thus saving us a great deal of trouble.

Boys who are fond of reading the story papers which contain such impossible tales, should try and change their reading, and for the sake of variety, if for nothing else, read some of the following works which we are sure they will find as interesting and much more instructive than anything found in the weekly story papers. Besides, the works named, are such, as every wise person will approve of, and which no parent or guardian will object to; and when we consider that a boy's reading is the most important part of his education, it is a matter worthy of our best attention to have placed in the hands of boys, books that will aid, rather than retard their acquirement of knowledge, and that will be at once both useful and elevating. If a boy takes kindly to sea stories, get him a "Biography of Paul Jones," Southey's "Life of Nelson," or Cooper's "History of the American Navy." After reading these he may be permitted to read "Cooper's sea tales" and Marryat's novels, books that are much healthier than most of the rose water sea stories of the present day. If a boy desires reading of a stirring kind in another direction, let him try one of Mr. Towle's series of books about the "Heroes of History," or Dr. Eggleston's "Lives of Famous Indians," and the reading of these will surely lead the boy on to a desire to know more of the "Heroes" and "Indians" of whom he reads, and then his mind will be ready to take in solid history with enjoyment and profit.

Among other works which the intelligent boy will enjoy, may be mentioned, "Robinson Crusoe," "Arabian Night's Entertainment," "The Swiss Family Robinson," "The Percy Tales" for short readings, "Tales of a Grandfather," "Tales of the Border," "Magna Charta Stories," by Arthur Gilman, and many others of a like nature.

Every book noticed in the present and

previous issues of the YOUNG SCIENTIST, may be placed in the hands of young people with safety, for we shall not notice any book in our columns of which we may have doubts as to its fitness to be read by our younger patrons. Any of the books we have named in the foregoing, when read by an intelligent boy, will prove just as interesting as any of the "HORRIBLE-EYED BILL, OF MURKY GULCH," kind of stories, and much more elevating and instructive.

Seldon informs us that the Christian Church, desirous of abolishing the Saturnalia of the Romans, a festival instituted in honor of Saturn, appointed a festival in honor of Christ, to supersede it. But the observance of the day did not become general until about the year 500. Many curious myths are told concerning Christmas eve, such as that if we go into a cow stable at 12 o'clock at night, we shall find the cattle kneeling; and if we visit bee hives at that time, we may hear the bees singing Christmas Carols to welcome the approaching day.

We deck our houses, schools, and churches with evergreens to remind us of the birth of the great Founder of our Church.

The laurel is used with other evergreens at Christmas, because of its use among the ancient Romans as the emblem of peace, joy, and victory.

The mistletoe is used in all Christmas decorations by the English. Its berries and its green are very beautiful. A full description of it is given in another column of the present number. A branch of the mistletoe is often hung over the doorway on Christmas eve, and if a gentleman can kiss a lady as she passes under the mistletoe, he has on *that* evening a right to the privilege.

The evergreens mostly used in this country are hemlock, spruce, laurel, Canada balsam, and the varieties of ground-pine. The bright red bitter-sweet berries gathered in the fall, add to the beauty of the wreaths.

We have frequently been asked the meaning of the initials affixed to crosses used on that day, such as I. H. C., and I. H. S. The former stands for these Latin words: "*Jesus Humanitatis Consolator*"—Jesus the Consoler of mankind; the latter, "*Jesus Hominum Salvator*"—Jesus the Saviour of men. On some very ancient crosses are found I. N. R. I., "*Jesus Nazarenus Rex Judeaorum*"—Jesus of Nazareth, King of the Jews.

The custom of giving presents at Christmas originated in Germany. It was derived from the ancient feast of Sol. The Christmas tree is of German origin also, and is, perhaps, the most pleasing way of giving presents to those we love.

Perhaps many of our readers will desire to make Christmas trees for their own homes, or for the schools or churches of which they are members; and it may not be amiss to offer a few suggestions regarding them: If the woods are not convenient where a suitable tree might have been found, and when it is necessary to purchase an evergreen from a nursery, a "silver fir" should be obtained if possible, as it is best adapted for the purpose. In large cities suitable trees are easily obtainable, as thousands of them are shipped there for sale. If woods are near, and free access may be had to them, and "silver fir" or "spruce" are not to be found, hemlock may be used; it is the prettiest green, but its branches are not sufficiently firm to bear any considerable weight. Branches may be nailed on here and there to make the tree symmetrical, and it may be trimmed if required. Slats may be used to strengthen the branches if necessary; but when this is done, they should be painted green with some non-poisonous paint mixed in rice water, or a weak solution of glue.

For the base of the tree, a half of a cask or barrel may be used, placing the greatest diameter on the bottom. A hole made through the end of the cask or barrel to admit the woody portion of the tree to pass through, and a brace nailed across the lower portion of the barrel with a hole in it for the foot of the tree to rest in, will make a solid base for the tree. A square box may be made to answer the purpose very well. If necessary, the cask, barrel or box may be screwed

to the floor. The base, whatever it may be, should be painted green, and covered with green moss and little branches of hemlock or pine. If paint is objectionable, green paper or cotton cloth may be used in place of the paint.

The tree, when completed, should be placed in a corner or the centre of the room, and have a white cloth spread under it, both to protect the carpet and to give brilliancy to the tree when the candles on it are lighted.

Pieces of tin cut diamond shaped, and hung thickly among the branches of the tree, will add much to its appearance. Tinsel and gold paper may also be used with good effect. Gilded glass balls and pendants, that may be obtained cheaply. Bright colored ribbons and variegated prints may be made use of with effect by any ingenious young lady or gentleman.

Indeed, when the tree is firmly set in place, the process of decoration may safely be left in the hands of the ladies of the household, who will, doubtless, make good use of all the advantages at hand, not forgetting the all-important Chinese lanterns, and the necessary wax tapers.

It is pleasing and encouraging to see that both pulpit and press are taking up cudgels against that bane of our young folks: "Dime literature." A few Sundays ago Dr. Crosby, in a sermon preached in his church, denounced the publication of the villainous stuff, and strongly advised parents to see that their children were provided with healthful reading. The following, which is taken from the New York *Telegram*, is to the point, and worth reproducing here:

"An interesting illustration of the manner in which dime novels act upon boy's brains has recently been given at Cleveland, where a boy aged fourteen was the organizer of a secret society, to be called 'The Society of the Silver Skulls.' The principles set forth by this delightful association included an unmitigated curse upon all those domestic and friendly relations which men hold dear, and the invocation of various appalling calamities upon whoever should prove a renegade. In the present age there is no reason why good and entertaining reading should not be furnished to boys and girls of all ages. Never has reading of this kind, intended especially for juveniles, so greatly abounded as at present. Never before have so many writers of talent, so many draughtsmen of skill and so many publishers of respectability, backed by money, lent their aid to supplying children with reading matter of the first order. The class of 'literature,' therefore, which comes under the denomination of the dime novel ought to die. Those parents must be very unwatchful or extremely foolish who can allow their sons to pursue a course of reading the tendency of which is to arouse all the worst instincts and extinguish all the best. The Cleveland youth recently disappeared from his home, taking with him two revolvers. This looks as if he were going to join either the cow boys or the Indians, a little fraternization with whom would perhaps dissipate his ideals."

ODD NOTES.

— Photography is one of the miracles of modern times. The art has taken strides with its seven league boots since the time of Daguerre, who made a picture on a metal plate, which had to be turned and twisted almost out of shape before you could find what you were looking after. Lately pictures have been taken with such rapidity that forked lightning is compelled to strike a faster gait to keep up with the process. Dr. Koch tells us that he has photographed with a photo-micrographic camera that most minute filament, the *flagellum* of the bacteria. One might be satisfied with photographing the bacteria as a whole, since it is beyond the reach of naked vision, but to take a picture of an insignificant portion of it is like getting up among fairy tales. Mr. Rockwood also has succeeded in getting satisfactory pictures of the vibrating point in the diaphragm of a telephonic instrument while a person was speaking at it, and by means of a spark from Leyden jars. The work must have been done in the one twenty-four thousandth part of a second. This rapidity

almost exceeds that with which a ward politician accepts office, and is only equalled by the readiness with which a poor girl accepts a rich husband.

— The sixth of a series of lectures by Professor Albert S. Bickmore was delivered on the 10th of November at the American Museum of Natural History. The lecturer took for his subject "Humming Birds." He said:—"Humming birds are only found in the New World. Their principal home is in Central and South America. A few, however, are found up as far as Hudson's Bay. Their favorite place is not in densely wooded forests, but in the open, where there are flowers and fruits. While this family of birds is confined to America, yet there are four hundred different kinds of them. They have two different motions of the wings—one producing the humming sound and the other propelling them the same as other birds. The humming bird lays only two eggs, which are not pointed at either end, but are elliptical. Humming birds take great care of their young. Frequently, when they are disturbed, the male will remove one egg and the female another to a different place."

The lecture was illustrated by a long series of photographic transparancies and by the collection of the museum, which is one of the best in America.

The subject of the next lecture will be "Pheasants and Doves."

— The annual fall games of the Athletic Association of the College of the City of New York took place on the 5th of November at the Manhattan Athletic Club Ground, Eighty-Sixth street and Eighth avenue. A one-hundred-yard handicap was won by E. B. La Fetra, class '86—time, $10\frac{3}{4}$ seconds. A half-mile handicap was won by Harris Smith, class '86—time, 2m. $17\frac{1}{5}$s. A one-mile handicap walk was won by C. A. Clinton, class '86—time, 8m. 59s. A two-hundred-and-twenty-yard hurdle race was won by C. F. Bostwick, class '87—time, $33\frac{1}{2}$ seconds. A one-mile bicycle race, handicap, was won by W. R. Ferris. In a spirited one-mile handicap run T. W. Martin, class '85, came in first—time, 5m. $15\frac{4}{5}$s. The quarter-mile handicap was won by A. J. Murberg, class '87—time, 63 seconds. In the running, broad jump, handicap, C. L. Woolley, class '88, came off victorious by 17 feet 4 inches. The baseball throwing competition was won by D. M. Marvin, class '84, his best effort being 281 feet $8\frac{1}{2}$ inches.

— Prof. C. V. Riley, the entomologist of the Department of Agriculture, has deposited with the Smithsonian Institute his own private collection of insects, with the idea of using it as a nucleus for the development of a collection fitting the dignity of a national museum. The collection deposited comprises some 30,000 species and upward of 150,000 specimens of all orders. The most important addition to the Institute has been Mr. Ridgway's private collection of American birds, containing 2,302 specimens of 778 species, especially important because the specimens have been selected in the field to illustrate variations of color and form due to age, sex and geographical location.

— President Barnard, of Columbia College, in a letter gave the result of careful computations which he had made relative to the disintegration of the Central Park obelisk's surface due to exposure to the weather. His opinion is that it will take 6,000 years of exposure in this climate to reduce the volume of the obelisk to the depth of 1 cm. on each side. "The waste in a century would be, therefore, scarcely a perceptible amount," he concludes.

— Children are very wise. While the philosopher and his family were quizzing each other as to what ought to be done in case of fire, little Jack said, "Father, what would you run for if the house were all ablaze?" The old gentleman declared that he should run for a very valuable manuscript. "I wouldn't," responded the boy; "I should run for the door."

— A party of Italian scientists have just returned from an expedition to the South Pacific, having proved to their own satisfaction that a race of giants once existed in Patagonia. In wandering over Terra del Fuego, they found human bones of marvellously large size.

Our Book Table.

Plaster and Plastering; Mortars and Cements. How to Make and How to Use. Being a Complete Guide for the Plasterer in the Preparation and Application of all kinds of Plaster, Stucco, Portland Cement, Hydraulic Cements, Lime of Tiel, Rosendale and Other Cements, with Useful and Practical Information on the Chemistry, Qualities and Uses of the various kinds of Limes and Cements. Together with Rules for Measuring, Computing and Valuing Plaster and Stucco Work. To which is appended an Illustrated Glossary of Terms used in Plastering, etc. Besides numerous Engravings in the Text, there are Three Plates, giving some forty figures of Ceilings, Centrepieces, Cornices, Panels and Soffits. By Fred. T. Hodgson. Industrial Publication Co., New York. Price (Cloth), $1.00.

For amateurs who have occasion to make plaster casts of any kind, or who may have to use mortar or cements of any kind, this book will be found valuable, as it contains rules and directions for using plaster-of-Paris, cements and mortars for many purposes that the enterprising amateur will sometimes require. Indeed, every man who builds, or has a house built for himself, would find this work a great help to him in understanding and appreciating the value and character of the plastering and stucco work he may have done. To the operative plasterer the work will prove invaluable.

HOLIDAY GIFT BOOKS.

The holidays are at hand, the days on which congratulations are given and received, and on which are made those little gifts that do so much towards tightening the bonds of affection and love that should always exist between friends and relatives. Among these gifts, books always take a prominent place, and we therefore take this opportunity to give such information on this point as we may collect, so that intending purchasers may be able to choose their books with some idea of what they are to get. We take pleasure, therefore, in submitting the following notices of Holiday Gift Books, with prices, when convenient, titles, and such other remarks as we may deem necessary for the interests of our readers. Indeed, we positively will not name a book in these columns that contains between its covers anything that might be considered objectionable.

The Recollections of a Drummer Boy. By Henry M. Kieffer, late of the One Hundred and Fiftieth Regiment, Pennsylvania Volunteers. Illustrated. Jas. R. Osgood & Co., Boston.

Here is a book that will please the boys if anything full of startling adventure, camp life, and funny escapades will. The book is full of interesting events and lively experiences. Relating to a period when the tocsin of war resounded from one end of the land to the other, a fact which gave the author, who took part in the events of those days, an opportunity of tieing together an authentic account of a number of actual events that must prove instructive to young readers, as well as interesting. The author's style is pleasant and easy, and the tone of the work throughout is commendable and elevating.

Three Vassar Girls in England. By Lizzie M. Champney, author of "Three Vassar Girls Abroad." Estes & Lauriet, Boston, Mass. Price $1.50.

It is pleasant to meet again these Three Vassar Girls with whom we once before enjoyed such charming journeyings on the continent; and who, in the present volume, take us through some of the loveliest spots in the mother country. The story itself is pleasantly given, but serves merely as a connecting link for the series of sketches of notable places, buildings, etc., many of them well known in history and fiction.

The yachting cruise in the *Coal Scuttle* gives us many pretty glimpses of the English coast with some of its legendary belongings. In the rambles taken through old towns and over country roads, one can almost see the old homesteads, ruined castles, and stately halls, and smell the violets and sweet brier hedge-rows.

The book is brought out in most attractive form. The illustrations with which it is profusely enriched are by such distinguished artists as Champ, and others equally well known. Many of the plates are full-page in size, and show us many renowned places, adding much to the value of the book. Both for the story itself and the pretty setting given it, the book is worthy a prominent place among the holiday volumes for the coming season.—C. A. H.

The English Bodley Family. By Horace E. Scudder. Houghton, Mifflin & Co., Riverside Press, Cambridge, Mass.

An excellent Holiday Book, being the history of a tramp through England by a group of merry young people, who exchange their opinions regarding historical places, personages, and events. When we say that several of the young people who are introduced to the reader are Americans, the fact will doubtless make our young readers more anxious to procure a copy.

The work is handsomely illustrated with fine wood-cuts of historical places and events, which add very much to its value and instructive quality. The pleasing style and general cheeriness of the work, make it easy and attractive reading.

The American Girl's Home-Book of Work and Play. By Helen Campbell. C. P. Putnam's Sons, New York.

Here is a book that will be hailed with pleasure by the girls, as it is designed exclusively for their use, and for their amusement and instruction. Do

they want to make ornamental work of paper, instructions are to be found here. Do they wish to make all kinds of paper toys, play games, act charades, celebrate Hallow-een, or make fun and amusement for the smaller children, by the aid of this book it may all readily be done.

Part the second gives rules and instructions for out-door games, such as Lawn Tennis, Archery, Croquet, Lawn Billiards, Swimming, Boating, and many other things a girl would like to know. Part the third explains about fancy work of various kinds. How to make Christmas Gifts from Paper, Leather, Bark and many other things. Wax-Flower Making, Wood Carving, Flower and Fruit Culture, Drawing, Designing and Cooking all come in for a fair consideration, and the whole is written in an easy and clear style, and is illustrated with a large number of descriptive cuts, which tend to make the text easily understood. Every house in which there is a girl should contain a copy of this book, for it contains a rich mine of innocent amusement and useful information.

Zigzag Journeys in Northern Lands; from the Rhine to the Arctic. By Hezekiah Butterworth. Estes & Lauriet, Publishers, Boston, Mass. Price (Cloth), $2.25.

This is an excellent book for young people, being amusing, instructive, and interesting. The subject is a history of a summer trip through Holland, Belgium, Germany, Denmark, Norway and Sweden, with historical sketches and anecdotes of the localities visited, and authentic picturesque views of many of the ruins, buildings, and places along the line of travel.

The style is easy and graceful, and the entertaining stories and romantic incidents that are interspersed throughout the whole work, make the book pleasant reading. Indeed, there are few holiday books now obtainable that contain better and healthier reading than the one before us.

Dooryard Folks and a Winter Garden. By Amanda B Harris. Illustrated. Boston: D. Lothrop & Co.

It will not be difficult for our readers to guess who are the "Dooryard Folks" that are described in this charming book. The author tells us all about the animals that frequent our gardens and near woods; about the mole, the mink, the weasel, the fox, the squirrel, the chip munk, and others. And the stories are told in a most delightful way. No young person who has any taste for nature can fail to be interested in the stories, and the author observes so closely, and tells her tale so truthfully, that her work deserves to take, on the shelves of our children's libraries, the place which White's "Natural History of Selborne" occupies on the book shelves of older persons. Parents who wish their children to become familiar with nature can find no better aid than this book.

The number of curious animals of comparatively large size that can be found, even in the vicinity of our large cities, is something surprising to those who have not been close observers. About our own dooryard, which is within twenty miles of New York City, and within less than half an hour's walk of a city of over 50,000 inhabitants, we find the fox, the rabbit, the weasel, the raccoon, the grey and the flying squirrel, besides several other four-footed animals, while amongst birds we find the whip-poor-will, the grouse, the heron, the quail, besides robins, blue-birds, jays, cat-birds, snow-birds, cedar-birds, blackbirds, high-holes, meadow larks, wild pigeons, ring doves, etc., etc. Leaving out the insects, the fauna of any hillside would form a wonderful collection if brought together.

Magna Charta Stories. Edited by Arthur Gilman, A.M. With Full Page Illustrations. Boston: D. Lothrop & Co.

We have here a series of twelve stories by different authors, who each in turn takes up the tale of some noble fight for liberty, and puts it in a shape to interest. No "Indian stories" can be more attractive; no tales of adventure more thrilling; and we sincerely hope that it will take the place of the trashy blood-and-thunder tales which are now so eagerly devoured by many boys.

A Year of Sunshine. By Kate Sanborn. James R. Osgood & Company, Publishers, Boston, Mass.

This is a spicy little book, and consists of numbers of cheerful extracts for every day of the year, selected and arranged by the author. The work has reached its second edition, and bids fair to become a permanent companion to many now in their childhood.

Miss Sanborn has succeeded in stringing together, in this book, many of the most pleasing gems in English literature, and the publishers have supplemented her efforts by presenting them to the public in a style of printing and binding that reflects credit on their judgment, good taste and liberality. Doubtless, thousands of these books will be given to lady friends by intelligent young men during the coming holidays.

Chatterbox for 1883 as usual leads the way for the crowd of books for the coming holidays. The book is full of cheery little stories, admirably adapted for the little ones of both sexes, and besides the stories it contains something like 200 full-page illustrations, all of which are finely engraved. We take pleasure in recommending this book as one worthy of being placed where young children may read it. (Boards, 4to., pp. 412.

Price $1.00. Estes & Lauriet, Publishers, Boston, Mass.)

Cassell, Petter, Galpin & Co., of London, Paris and New York, have just issued their very pleasing gift books for children of small and of large growth. One of them is entitled "Little Folks," and it is really a magazine for the young, consisting of a new and enlarged series. Another is "Sunlight and Shadow," and consists of poems and pictures of light and nature. It is worth remarking, however, that very few poets of note figure in these pages. The third volume is entitled "Jingles and Joys for Wee Girls and Boys," by Mary D. Brine. It fulfils its mission in a very desirable manner and is doomed to popularity.

Astronomy for Amateurs.—December.

BY BERLIN H. WRIGHT.

(All Computations are made for the Latitude and Meridian of New York City.)

THE PLANETS.—DECEMBER, 1883.

Mercury will not be visible in December.

Venus will be five degrees south of the Moon on the first, and about seven on the 31st. She is moving eastward past the stars of the constellation Sagittarius. At the beginning of the month she will be just above the bowl of the Milk-maid's Dipper, and at the close just below the only conspicuous stars in Capricornus—the three of the 3d magnitude in the head of the Goat. She sets as follows:

December 10th—5 49 evening.
" 20th—6 9 "
" 30th—6 33 "

Mars' position has changed but little since last month, being still near the Sickle in Leo, and rising as follows:

December 10th—9 17 evening.
" 20th—8 41 "
" 30th—7 59 "

Jupiter is keeping company with Mars, being about one hour or 15 degrees west of him, and rising as follows:

December 10th—7 54 evening.
" 20th—7 11 "
" 30th—6 26 "

He will be 5 degrees north of the Moon on the 16th. The eclipses of his satellites visible this month are:

Sat.	D.	H. M.		
I.	5	3 26	morn.	Beg.
I.	6	9 54	eve.	"
II.	8	9 12	"	"
IV.	11	10 43	eve.	Beg.
IV.	12	2 37	morn.	end.
I.	13	11 47	eve.	Beg.
II.	15	11 48	"	"
I.	21	1 41	morn.	"
I.	22	8 9	eve.	"
II.	23	2 25	morn.	"
I.	28	3 34	"	"
IV.	28	8 53	eve.	end.

During December the shadow of Jupiter is directed slightly to the right, and as the satellite passes from right to left, all of the above beginnings or disappearances must occur to the right or west of the planet, and as Satellite IV. is so much further removed than the others, his reappearance will be visible, but very close to the western limb of the planet.

Saturn will be in close conjunction with the Moon on the 12th, being but one half of one degree north of that luminary He passes the meridian as follows:

December 10th—10 58 evening.
" 20th—10 16 "
" 30th— 9 34 "

METEORS OR SHOOTING STARS.

The month of December is not remarkable for meteoric displays, however several quite active groups are encountered.

The Andromedes and Geminides mentioned last month, continue into December; the first until the 7th, and the last until the 27th. The Taurids II., radiating from near the great Crab Nebula, 3° S. of Beta Tauri (Aurigæ), Dec. 6th—12th. The Polarids I., from very near the Pole star after the 20th, and a few from near the middle star in the handle of the Great Dipper, in Ursa Major, are the principal ones visible in December.

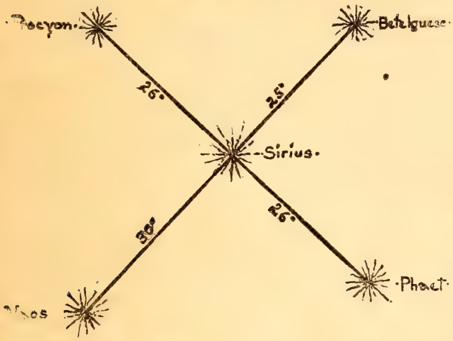
SITUATION OF THE PRINCIPAL STARS, CLUSTERS, AND CONSTELLATIONS IN DECEMBER, AT 9 P.M.

The most beautiful and interesting portion of the firmament, is presented to our view in the evenings of December, January and February. In December the portion lying east of the meridian, possesses the greatest array of glorious objects.

Mira, the wonderful variable, is near the meridian and just below the equator of the heavens. This star has a period of 331d. 8h. 16m. (Peters), and will not be at maximum again until next spring, being now on the decline and almost invisible. It changes from a 3d. magnitude star, to invisibility. A south-east diagonal through the square of Pegasus, produced one and one-half times as far, reaches it. To the left 15°, is the 2d. magnitude star, Menkar, in the head of the Whale, and the only bright star in that large constellation. The Ram, with one bright star in a cluster of dim ones, lies 20° N., and the head of Medusa, of which cluster the variable Algol is one, is in the zenith.

To the left, or east of the meridian, the zodiacal constellations are, in their order from W. to E.: Tauris, Gemini, Cancer and Leo. In the first, are the Pleiades, Hyades and Saturn; in Gemini, the bright stars Castor and Pollux

and a host of other interesting objects; in the next, Jupiter and Præsepe; and in Leo, Mars Regulus and the Sickle. South of the zodiac is a still more brilliant field. Low down in the south the two brilliants, Phaet in the Dove, on the right, and Naos in the Ship on the left, 30° apart, form the southern termini of the legs of the Great Egyptian **X**, having the great Sun, Sirius as its centre, and Procyon in the Lesser Dog, and Betelguese in Orion as the northern termini thus:



To the right of Sirius is the Hare, indicated by a neat four-sided figure, and above it is Rigel. The Trapezium and the Kings or "Stars of Orion's Belt," and Leo and the Sickle, are rising.

To the west or right of the meridian Andromeda, just N.E. of the Great Square of Pegasus, and the **λ** in Aquarius. S.W. of it are the most conspicuous objects. Away in the N. W. we see the Great Cross, with Deneb at its head, and lying in the Milky Way; and the Harp and Vega, two most beautiful objects.

In the circumpolar regions, the Great Dipper, in Ursa Major, is low down and a little to the East. The Little Dipper, Draco and Cassiopeia, are to the left or west of the pole, and the Segment of Perseus, Auriga and Capella, are to the right.

EPHEMERIDES OF THE PRINCIPAL STARS AND CLUSTERS, DECEMBER 21ST, 1883.

		H. M.	
Alpha Andromeda (Alpheratz)	in merid.	6 2	eve.
Omicron Ceti (Mira) variable,	"	8 13	"
Beta Persei (Algol) "	"	9 0	"
Eta Tauri ("Seven Stars" or Pleiades)	"	9 40	"
Alpha Tauri (Aldebaran)	"	10 28	"
Alpha Aurigæ (Capella)	"	11 7	"
Beta Orionis (Rigel)	"	11 8	"
Alpha Orionis (Betelguese)	"	11 48	"
Alpha Canis Majoris (Sirius or "Dog Star") rises		7 39	"
Alpha Canis Minoris (Procyon) rises		7 14	"
Alpha Leonis (Regulus)	"	9 17	eve.
Alpha Virginis (Spica)	"	1 58	mor.
Alpha Bootis (Arcturus)	"	1 1	"
Alpha Scorpionis (Antares) invisible			
Alpha Lyræ (Vega) sets		9 26	eve.
Alpha Aquillæ (Altair) sets		8 14	"
Alpha Cygni (Deneb) "		0 36	mor.
Alpha Pisces Australis (Fomalhaut) sets		8 50	eve.

De Land, Florida.

Novelties for Amateurs.

A number of excellent devices were on exhibition at the American Institute Fair this year, suitable for amateurs and amateur work. Among which we may mention. (1) The Economic Motor, manufactured by the Economic Motor Co., 28 Beekman Street, New York. This is a first class motor for amateurs using lathes, scroll saws, or other machines requiring power from one-half man to four men, and as the cost is only from $75 to $175, the motors may be considered cheap. The power is derived from the rapid ignition in the cylinder of a combustible mixture of illuminating or heating gas and air, which enters the cylinder through automatic valves. When the amount necessary to propel the piston has been drawn in, ignition takes place, and the piston is forced upward to the top of the cylinder, imparting a rotary motion to the crank-shaft and fly-wheel. The momentum of the latter completes the revolution, driving out the product of combustion through an exhaust valve, when the gas and air enter again and the operation is repeated.

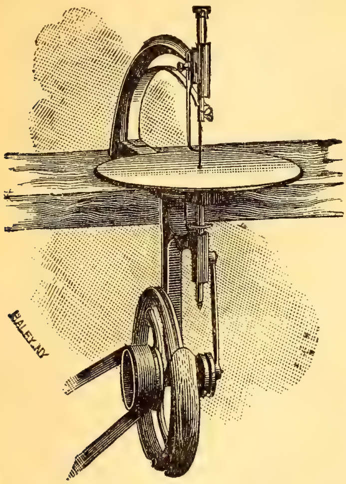
(2) Another useful machine for amateurs—or professionals, for that matter—is the adjustable mitre-planing machine, exhibited by Theodor Schreppel & Co., of 101 Bowery, New York.

This is simply a mitering machine worked with a lever and rack, and is a decided improvement over the old style mitering machines. The facility with which it is worked does away with the necessity of having the attendance of two men to turn out good work, the employment of the lever and rack enabling even a boy to use both cutters without changing his position or using extraordinary exertions, and therefore twice as much work can be easily performed by a boy or unskilled mechanic with this machine than could have been performed by two skilled men with the old fashioned machines. The machine being entirely constructed of metal, the changes of the temperature and atmosphere have no effect upon the same.

(3) Of scroll saws there were quite a number, among which may be mentioned the Challenge and Rival, manufactured by the Seneca Manufacturing Co., and Barnes & Co., of Rockford, Ill.

The Seneca Manufacturing Co. have also in

the market, a new saw, No. 4, which is so arranged that it may be attached to table or workbench. It is simply a new and cheap arrangement of the Challenge Scroll Saw for power, and is easily fastened with screws or bolts to a work bench or any place desired; takes but little room, and is a very



desirable machine for manufacturing purposes, etc. It is driven by a one inch flat belt; has the same capacity for cutting, etc., as the Challenge machine, but has no drilling attachment. The Challenge lathe attachment can be used on this machine.

Besides machines, there were a number of other articles exhibited that many of our readers would no doubt like to know something of.

One of the most artistic, and, as it appeared to us, a useful and instructive article, was a table lamp, exhibited by C. F. A. Hinrichs, of Nos. 29–33 Park Place, New York. The lamp, handsome in itself, and artistically decorated, possessed its greatest value, from our point of view, from the fact that the shade of semi-transparent glass was nearly spherical in shape, and represented a globe of about eight inches in diameter, having on its face the continents, islands, seas, and oceans, shown in colors the same as an ordinary school globe. It will readily be seen how useful this lamp would be where there are children studying geography, after school, during winter evenings. We need not add, that older folks would find this arrangement useful and pleasing when reading in their evening papers of the doings and misdoings of the denizens of distant lands. One of these globe shades should be in every house.

Palm & Fechteler, No. 6 West Fourteenth street, New York, had on exhibition a beautiful assortment of silk and decalcomania ornaments suitable for decorating odor bottles, tidies, cushions, lamp shades, sachets, etc.; in fact, any article made of silk, linen or cotton. The various designs of silk ornaments form very attractive decorations in themselves. However, more handsome and extremely elaborate ornamentations can be made by tastefully combining a variety of the designs, or parts thereof, to almost any desired shape. This method gives considerable scope for a large variety of ingenious designs that may be created by the personal talent and inventive abilities of the amateur.

The Murray Hill Publishing Co., of 129 East Twenty-eighth street, New York, exhibited a novelty called the "Polyopticon," which consists simply of a lamp shade made of heavy binder's board, neatly covered with leatherette, and has metal parts as required, including two reflectors. It is made so as to be easily adjusted to all round-wick or argand lamps (those using straight or students-lamp chimneys), and as these are the best lights for reading, they are to be had almost everywhere. It rests on argand (round wick) burners in such a way as to permit the regulating of the light below. With a good light it is possible to show a picture on a screen six feet distant, and a circle of light four feet in diameter. This makes a common photograph appear four hundred times its real size, or about fifteen times "as large as life." By shortening the distance of the Polyopticon from the screen, the picture becomes brighter and smaller, and can be reduced to "life size," or any size that is desired for sketching a portrait. Thus it is of use to artists. Anyone handy with a pencil can make funny sketches, faces with movable eyes or tongue, or a donkey that can move his ears, and produce effects equal to those made by special "slides" that cost two or three dollars a piece. It is certainly fair to say that all magic lanterns costing under $25 are outdone by the Polyopticon, and that the latter is just the thing for every home that wants a private show for its own amusement. In no other way can so much fun be had for the same amount of money. The instrument complete with a number of views costs less than six dollars. This instrument is capable of affording an immense amount of amusement for the "family circle," or even a gathering of friends.

Scientific News.

—The oldest tree in the world, so far as any one knows, is, says *Knowledge*, the Bo tree of the sacred city of Amarapoora, in Burmah. It was planted 288 B.C., and is therefore now 2,170 years old. Sir James Emerson Tennent gives reasons for believing that the tree is really of this wonderful age, and refers to historic documents in which it is mentioned at different dates, as 182

A.D., 223 A.D., and so on to the present day. "To it," says Sir James, "kings have even dedicated their dominions, in testimony of a belief that it is a branch of the identical fig tree under which Buddha reclined at Urumelaya when he underwent his apotheosis." Its leaves are carried away as streamers by pilgrims, but it is too sacred to touch with a knife, and therefore they are only gathered when they fall. The King Oak in Windsor Forest, England, is 1,000 years old.

—The just now popular word dude, meaning an empty-headed, languid-mannered young swell who bangs his hair, proves to be no foreign importation, but, like many another expressive term, to be of good New England parentage. The word (pronounced in two syllables) has been used in the little town of Salem, N. H., for twenty years past, and it is claimed, was coined there. It is common there to speak of a dapper young man as a "dude of a fellow," of a small animal as "a little dude," of a sweetheart as "my dude" and of an æsthetic youth of the Wilde type as a dude. But how the word attained so sudden and widespread a notoriety puzzles Salem. Its revival at New York is credited to a distinguished Englishman, who remarked, after visiting a rich club, that the young men were all "dudes."

—In a recent lecture on solar physics at the Royal Institution, Sir Wm. Siemens gave his reasons for setting the temperature of the photosphere of the sun at about 2,800 degrees C., instead of about 10,000 degrees, where Rosetti and other late investigators put it. He agrees, in this lower estimate, with Violle, St. Clair, Deville, and Sir William Thompson, and thinks the solar temperature can not much, if at all, exceed that of the most powerful electric arcs. He recognizes fully the fact that a temperature higher than 3,000 degrees C. would be absolutely conclusive against his theory that the solar heat is due to the recombination or burning of compound gases at the surface of the sun. He bases his estimate of the solar temperature upon three foundations: First, the behavior of a carbon rod and a small gas flame in the focus of a reflector exposed to the sun; second, on a comparison between the spectra of various lights—for instance, the Argand burner, an incandescent lamp, the electric arc, and the sun itself, as observed by Langley on Mount Whitney; third, upon experiments on the relation between radiating power, made by means of a long platinum wire heated by an electric current.

Practical Hints.

—In New York City, a short time ago, a man died from poison, communicated while handling some buffalo hides sent from India. His companion worker employed on the same job was taken sick, and after a severe illness finally recovered. Both the men became warm, perspired freely, and repeatedly wiped the sweat from their faces with the bare hand, each of the men having a pimple on the face. Whether the death of the one and the illness of the other was caused by the virus from the hide of a diseased animal, or by the absorption of arsenic used in the preservation of the hides, is not positively known. Probably, however, the cause was disease communicated from an infected animal through its hide, as the Calcutta packers use, frequently, an arsenical preparation on the hides to kill a small brown worm that otherwise might destroy the hides, and instances of poisoning in handling these hides are not uncommon. Some years ago an importer of hides in New York died irom the effects of a bite or sting of a fly which inhabited the loft where the hides were stored.

—Christian Knab, in Munchberg, Bavaria, makes a blue preparation good for marking trunks and boxes, because it readily combines with wood, cloth, etc., and resists the action of the weather. His process is given in the *Deutsche Industrie Zeitung* as follows: 100 pounds of a 30 per cent. fluid extract of logwood are put in a suitable kettle, with 3 quarts of alcohol, to which 2 pounds of hydrochloric acid has already been added.

The mixture is kept at 68° Fahr., and well stirrred until thoroughly mixed. Next he dissolves 10 pounds of (yellow) chromate of potassium in 30 pounds of boiling water, and adds to it 20 pounds of hydrochloric acid, stirring well, and when it has cooled to 86° Fahr., stirs it very slowly into the mixture already in the kettle. The whole is then warmed to about 185° Fahr. The mass, which then becomes an extract, is stirred a short time longer, and to it is added 30 pounds of dextrine mixed with 20 pounds of fine white earth (terra alba), and well stirred through. The mass, when taken from the kettle, is put into a mill, where it is thoroughly worked together. It is, lastly, put into tin boxes and left standing a long time to dry out.

—The fine scrapings of any common cattle's horn steeped in vinegar and bound hot as can be borne upon a wound, will subdue pain almost instantly, and effectually subdue lockjaw. I have often used this remedy, and have never had a failure. In wounds torn and lacerated, as, for example, where a nail has been stepped on penetrating the sole of the foot, and the patient wild with pain, countenance livid, teeth chattering, limbs trembling and lockjaw seeming inevitable, with this remedy I have produced perfect quiet, relaxation of muscles and freedom from pain, and even from soreness of the wound, in the space of fifteen minutes time. I was called in haste to see a young man of 15 years who had stepped on a nail I found him almost in spasms, and had no remedies with me. In the house I found a powder horn, and with a piece of glass went to scraping. As soon as I had a common thimbleful I barely covered it with vinegar and heated it as hot as could be borne, and, setting others to scraping, I applied it to the wound, changed often as soon as cool, adding the scraping accumulated, and with this treatment had the boy easy and out of danger in fifteen minutes. I know not what there is in horn that produces this effect, which I have seen many times, and

have often wished there might be some preparation of this remedy a little more convenient to use than the crude material.—Dr. S.

Notes and Queries.

In continuing this department, which has been found of so much value, we would remind our readers who wish for information on any of the arts and sciences, that they are cordially invited to make their wants known through this column, and those of them who can furnish accurate answers to questions asked are requested to send in replies. Doubtless many of our subscribers may know of methods, processes, or devices that may be better or more suitable for the particular case in question than anything generally known, and it is this reason that induces us to keep this department open for a medium, where an interchange of ideas and practices may be made to the advantage of all our readers. Correspondents will please send their full address when forwarding their communications—either questions of answers—not for publication, unless expressly so stated, but so that we may know where to find the writer if desirable. Communications should be sent in on or before the first or each month previous to publication, to insure insertion in next issue.

Answers.

152. Amateur.—In general nothing more is necessary, after ascertaining your joint is perfectly straight, and as is technically called, out of winding, than to glue both edges, with the glue quite hot, and rub them lengthways till the glue is nearly set, but not chilled; however, when your wood is spongy, or sucks up the glue, the following method will be advisable, as it strengthens the joint, and does away with the necessity of using the glue too thick, which should always be avoided, as the less glue there is between the joint, provided they touch one another, the better, and when the glue is thick, it sooner chills, and we cannot well rub it out from between the joints; the method is to rub with a piece of soft chalk each joint on the edge, and wipe it off again with your finger, so that no lumps remain, and then glue it in the common way; it will be found to hold much faster, particularly when the wood is porous, than when glued without the chalk.—Chip.

153. Episcopalian.—The following explanations are, perhaps, all you will require:

EMBLEMS OF GOD AND THE FATHER.

1. "The Hand Issuing from the Clouds"—Represented either entirely open, in the act of bestowing, or with fingers arranged according to the Greek or Roman gesture of benediction.
2. "The Face, or Bust, in the Clouds"—Not used in modern times.
3. "The Triangle"—Represented with the name of the Father, in Hebrew, in the centre, and surrounded by rays, the triangle symbolizing the Trinity, and the whole sometimes contained in the circle, the emblem of eternity.
4. "The Flood of Light"—(Esek. viii. 2.)

EMBLEMS OF GOD THE SON.

5. "The Fish"—The Greek word for fish (*icthus*) is composed of the initial letters of the Greek words which mean "Jesus Christ, Son of God. Saviour." The fish is one of the most ancient and most common Christian emblems, and has many significations, for which see below.
6. "The Cross"—Christ's suffering; the humanity of Christ.
7. "The Lamb"—This was the type of the Saviour in the Old Testament. See also John i. 28. Bearing a cross, or banner, called the Lamb of God. Represented with a nimbus or aureole.
8. "The Lion"—"The Lion of Judah."
9. "The Vine."

EMBLEMS OF THE HOLY SPIRIT.

10. "The Dove"—The usual representation.
11. "A Man, or a Child"—(Mediæval)—often shown accompanied by a dove.

EMBLEMS OF THE TRINITY.

12. "Three Triangles"
13. "Three Circles"—Circles and triangles were often intermingled.
14. "Three Human Beings," accompanied respectively by the appropriate symbols of the three persons of the Trinity.
15. "Three Fishes."
16. "Two Human Figures," with a Dove between them.
17. "The Father" holding by the cross-beam, a cross with the figure of Christ upon it, and a dove proceeding downwards from the lips of the Father.
18. "The Trefoil or Clover-leaf."—Clericus.

154. Kino.—Guinea-pigs must be kept very cleanly, else their places are apt to smell disagreeably. They are fond of changes of diet. Give oats or grain of some kind once a day, and bread soaked in milk; also an allowance of garden roots, cabbage, greens of any kind, or weeds, such as sowthistle, plaintain, etc. They ought to have water to drink.—Keeper.

155. F. K.—A first-class violin has seventy separate parts. Two form the back, two the belly, six the blocks, six the sides, twelve the lining, twenty-four the purfling, and there is the tail-pin, its peg and fastening, the tail-piece, the bass-bar and sound-post, the bridge, nut, head and scroll, the finger-board, and the four pegs and four strings. The body weighs about half a pound, with the neck and scroll about twenty ounces, and when tuned to pitch the pressure on the bridge is over ninety pounds.—Fiddler.

156. Katie B.—Skins of all kinds can be dressed for making trimmings or muffs simply enough as follows: First, as to cleaning. Stretch the skin, feather, or fur downwards on a board, and tack it there; then with a knife remove every bit of flesh and fat, and scrape it well; then rub over with alum and soda pounded together in a little water; leave it to dry for a day or two, then scrape again and rub down with pumicestone to soften. A final dressing of alum alone will suffice to preserve it, and softening can only be performed by the application of elbow-grease.

Try to obtain fresh skins, if the fur pulls out they are useless. Cut open the skin so as to get at all the fleshy parts, then get some soap-suds or rain water, and well soap them (care being taken in not having water too hot), let them lie for six hours in the water, then well rinse them in clean water, take off all fat and flesh that may adhere to the skin. Then get some bran, and put some in the bottom of a pan, or tub, putting a layer of bran between each skin, then put cold water, till by pressing the bran on top of the skins you can see the water come through, let them stay for two days. Prepare a mixture of 3 parts ground alum and 1 part salt into a paste by adding cold water, and well rub into every part of the skin on the fleshy side, then make a wooden frame, and stretch the skin on it; let it lie, hair downwards, for twelve hours, then go over with the mixture again. Hang up to dry, if possible, where the sun can shine on them. Before they get quite dry, get a piece of pumice-stone and well rub the inside of the skin, and you will find that all the fleshy part will peel off, and leave the skin white, and if the pumice-stone is persevered with, will be perfectly pliable. If the skin should be an extra hard one, go over with the mixture again, adding a little more water, and finish again with pumice-stone. I have nearly a hundred skins made into rugs, which have been in use six years, and they are as good as ever they were. This is my own way of curing them perhaps some one of the readers of the Young Scientist may know of some quicker way. I cannot enlighten you in any other way to make them soft, the principal thing

in regard to that, is the stretching on the wooden frame.—SADIE.

157. ANXIOUS.—When a canvas is broken, rent, or perforated in any part, the piece of canvas that is used to repair the damage is dipped into melted wax, and applied the moment it is taken out, warm as it is, to the part, which has been previously brought together as well as possible, and also saturated with the wax. With great care you flatten down the piece; so that as the wax chills and concretes, the parts adhere and are kept smooth. The whole being made perfectly level, and the excess of the wax removed, a mastic made of white lead mixed with starch is applied; for oil-color does not adhere well to wax. The white is afterwards colored thin, or by washes, according to the tone of the surrounding parts, and repainted.—NEPTUNE.

158. WILLING TO LEARN.—Here are a number of recipes for ebonizing, all of which are said to be good:

1. Infuse gall-nut in vinegar into which rusty nails have been soaked; paint the wood with this, and polish and burnish when dry. 2. Wash the wood repeatedly with a solution of sulphate of iron, made by dissolving 2 oz. of sulphate in a pint of hot water. When dry, apply a hot decoction of logwood and nut-gall two or three times. When dry, clean with a wet sponge and then polish. 3. Brush the wood with a strong decoction of logwood chips several times. When dry, give it a coat of vinegar in which rusty iron has been placed. Dissolve beeswax in turpentine by setting in a warm place; apply warm with a brush, and rub it till it shines. 4. Wash with a concentrated aqueous solution of logwood several times, and then with a solution of acetate of iron of 40 deg. Baume. Repeat till a deep black is produced. 5. Put 2 oz. of logwood chips with 1¼ oz. of copperas in a quart of water, boil, and lay on hot. When dry, wet the surface again, with 2 oz. of steel filings dissolved in half a pint of vinegar. When dry again, sand-paper smooth, then oil, then fill in with powdered dropblack mixed in the filter. Work to be ebonized should be smooth and free from holes. Give it a light coat of quick drying varnish, then rub with finely pulverized pumice-stone and linseed oil until very smooth. 6. Boil ½ pound of chip logwood in two quarts of water, and add ½ oz. of verdigris, and ½ oz. of copperas, strain, and put in ½ pound of rusty steel filings. With this go over the work a second time. 7. A pound of logwood boiled in four quarts of water, add two handfuls of walnut shells or peel, boil up again, take out the chips, add a pint of vinegar, and apply boiling. Afterwards dissolve 1 oz. of green copperas in a quart of boiling water and apply hot. 8. First sponge the wood with a solution of chlorhydrate of aniline in water, to which a small quantity of copper chloride is added. When dry, go over again with a solution of potassium bi-chromate. Repeat this twice or thrice. 9. One gallon of vinegar, ½ pound of green copperas, ¼ pound of China blue, 2 oz. nut-gall, 2 pounds extract of logwood. Boil all these over a slow fire, and add half a pint of iron-rust. Apply as usual. A good varnish for ebonized work is made by dissolving in alcohol some black wax.—X.

159. SADIE.—In answer to Sadie, for instructions how to take impressions of ferns, etc., I will describe the method I adopt, which is—Procure some smooth cartridge paper, then take the ferns or leaves and arrange them in position. If ferns, they look well put in groups; if ivy, it will look well as a border, but whichever it is, put a pin through a leaf here and there, to keep the fronds from moving—very fine pins, or the holes will show. Then procure a small tooth-comb, a stick of Indian ink, and a tooth-brush. Dissolve the ink in water—don't get it in lumps—and dip your brush in the ink—do not get too much on—and rub in gently along the comb, holding it over the group of ferns. If you get too much ink on your brush, it will fall in big drops; the object is to make them as fine as possible. Rub more on near the joints of the ferns, just as in a photograph, and let the color gradually die away to the edge. Take the ferns off, and you will be surprised at the effect you have produced. If done neatly your ferns will bear a strong resemblance to a large-sized photograph. I shall be happy to supply further instructions if these are not sufficient.—KATIE V.

160. ETCHING.—Etching will find this a ticklish job, and great care must be used with the acids in working. He can try the following on a piece of plain glass first, and if it answers, well and good, if not let him write again and I will send another: this being a recipe I have by me, so cannot speak as to its merits. The glass to be etched should first be heated then coated with an even film of wax or paraffin, melted; soon as set, proceed to etch the design or pattern through it with a fine point or graver. Next obtain or make yourself a shallow lead tray and put in it some floride of calcium (fluor spar), in fine powder, mix to a thin paste with some strong oil of vitriol, and place tray on a warm sand bath, which is a box of sand made hot in the oven, when hot enough it will keep hot for some time after; now place the glass tightly over the tray so that the corroding gas comes in contact with the surface exposed by the lines etched. In ten minutes the design will be etched the lines being translucent. If desired to make the etching opaque (white), the plate should be wet before exposing it, a little benzole will remove the superfluous wax or paraffin from the glass.—DIAMOND.

Queries.

1. TURNPIKES.—Can any one tell me why long country roads are sometimes called "Turnpike Roads?"—CURIOUS.

2. DISTEMPER.—Having a fine mastiff dog that appears to be suffering with distemper, I should be pleased if some fellow reader would give me some instruction how I should treat him.—KANSAS.

3. PAINTING PHOTOGRAPHS.—What is used as a medium for painting photographs? Any information will be appreciated by YOUNG CAMERA.

4. VARNISHING PAPERS, PICTURES, OR MAPS.—I have a few colored pictures and maps I should like varnished, and would like to know how the paper should be prepared for receiving the varnish. If some brother amateur who knows all about it, will kindly publish the required information in these columns.—KANSAS CITY.

5. BARBER'S POLES.—Can anyone tell me why barbers always have their signs, or poles, painted in stripes? It seems such a curious practice, that I would like to know its origin if it is traceable.—SIMPLICITY.

6. DAGUERREOTYPES.—Is it known when likenesses were first taken in this country, by aid of a camera?—KANSAS.

7. BRONZE GILDING.—I have tried to gild in bronze on several occasions, but, somehow or another, I never can get the work done sufficiently good enough to satisfy my ideas of good work. If any reader of the YOUNG SCIENTIST should know anything of the process, he or she will have my thanks, by publishing it in the YOUNG SCIENTIST.—AMATEUR.

8. MAHOGANY STAIN.—Will some one publish a recipe for staining mahogany color?—NEFF.

9. POLISHING SCROLL-WORK.—Having some scroll-work to polish or varnish, I would like a few hints on the subject, if not asking too much.—NEW SUBSCRIBER.

10 TURNING ROUND BALLS.—I want to make some round balls in the lathe, and would like to know what sort of an attachment to use for the purpose; will some "expert" amateur "rise and explain," and oblige a NOR-WESTER?
